Flat-Ring Cyclide Coordinates

A coordinate system similar to TOROIDAL COORDINATES but with fourth-degree instead of second-degree surfaces for constant μ so that the toroids of circular CROSS SECTION are replaced by flattened rings, and the spherical bowls are replaced by cyclides of rotation for constant ν. The transformation equations are

$$x=\frac{a}{\Lambda}\operatorname{sn}\mu\operatorname{dn}\nu\cos\psi \tag{1}$$

$$y=\frac{a}{\Lambda}\operatorname{sn}\mu\operatorname{dn}\nu\sin\psi \tag{2}$$

$$z=\frac{a}{\Lambda}\operatorname{cn}\mu\operatorname{dn}\mu\operatorname{sn}\nu\operatorname{cn}\nu, \tag{3}$$

where

$$\Lambda\equiv 1-\operatorname{dn}^2\mu\operatorname{sn}^2\nu \tag{4}$$

and with $\mu\in[0,K]$, $\nu\in[0,K']$, and $\psi\in[0,2\Pi)$. Surfaces of constant μ are given by the flat-ring cyclides

$$\begin{aligned}&(x^2+y^2+z^2)^2+\frac{a^2}{k^4}\\&\quad\times\frac{(1-k^2)^2-2(1-k^2)\operatorname{dn}^2\mu+(1+k^2)\operatorname{dn}^4\mu}{\operatorname{dn}^2\mu\operatorname{cn}^2\mu}z^2\\&\quad-a^2\left(\operatorname{sn}^2\mu+\frac{1}{\operatorname{sn}^2\mu}\right)(x^2+y^2)+\frac{a^4}{k^2}\\&=0,\end{aligned} \tag{5}$$

surfaces of constant v by the cyclides of rotation

$$\left[\frac{\mathrm{dn}^2 v}{a^2}(x^2+y^2)+\frac{\mathrm{cn}^2 v}{a^2\,\mathrm{sn}^2\,v}z^2\right]^2-\frac{2\mathrm{cn}^2 v}{a^2\mathrm{sn}^2 v}z^2-\frac{2\mathrm{dn}^2 v}{a^2}\times(x^2+y^2)+1=0, \quad (6)$$

and surfaces of constant ψ by the half-planes

$$\tan\psi=\frac{x}{y}. \quad (7)$$

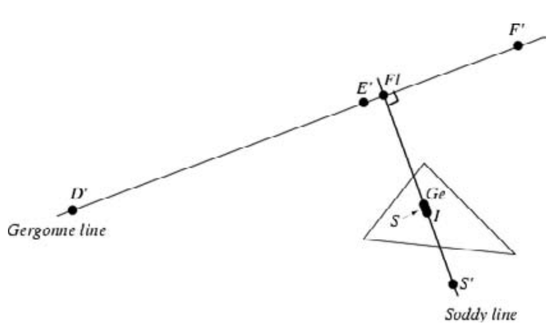
Flattening

The flattening of a SPHEROID (also called OBLATENESS) is denoted ϵ or f. It is defined as

$$\epsilon \equiv \begin{cases} \frac{a-c}{a} = 1-\frac{c}{a} & \text{oblate} \\ \frac{c-a}{a} = \frac{c}{a}-1 & \text{prolate,} \end{cases}$$



where c is the polar RADIUS and a is the equatorial RADIUS.

Flexatube

A FLEXAGON-like structure created by connecting the ends of a strip of four squares after folding along 45°

diagonals. Using a number of folding movements, it is possible to flip the flexatube inside out so that the faces originally facing inward face outward. Gardner (1961) illustrated one possible solution, and Steinhaus (1983) gives a second.

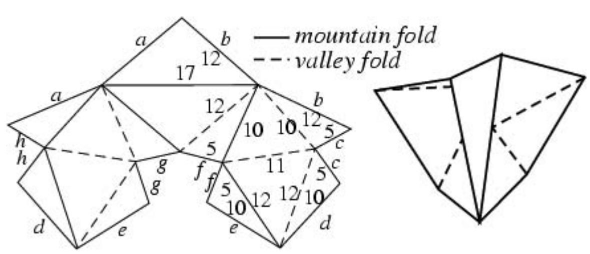
Flexible Graph

A GRAPH G is said to be flexible if the vertices of G can be moved continuously so that (1) the distances between adjacent vertices are unchanged, and (2) at least two nonadjacent vertices change their mutual distances. A graph which is not flexible is said to be RIGID.



See also RIGID GRAPH

Flexible Polyhedron

Although the RIGIDITY THEOREM states that if the faces of a *convex* POLYHEDRON are made of metal plates and the EDGES are replaced by hinges, the POLYHEDRON would be RIGID, concave polyhedra need not be RIGID. A nonrigid polyhedron may be "SHAKY" (infinitesimally movable) or flexible (continuously movable; Wells 1991).

In 1897, Bricard constructed several self-intersecting flexible octahedra (Cromwell 1997, p. 239). Connelly (1978) found the first example of a true flexible polyhedron, consisting of 18 triangular faces (Cromwell 1997, pp. 242–44). Mason discovered a 34-sided flexible polyhedron constructed by erecting a pyramid on each face of a CUBE adjoined square ANTIPRISM (Cromwell 1997). Kuiper and Deligne modified Connelly's polyhedron to create a flexible polyhedron having 18 faces and 11 vertices (Cromwell 1997, p. 245), and Steffen found a flexible polyhedron with only 14 triangular faces and 9 vertices (shown above; Cromwell 1997, pp. 244–47; Mackenzie 1998). Maksimov (1995) proved that Steffen's is the simplest possible flexible polyhedron composed of only triangles (Cromwell 1997, p. 245).

Connelly *et al.* (1997) proved that a flexible polyhedron must keep its VOLUME constant, confirming the so-called BELLOWS CONJECTURE (Mackenzie 1998).

Flip Bifurcation

Let $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be a one-parameter family of C^3 maps satisfying

$$f(0,0) = 0$$

$$\left[\frac{\partial f}{\partial x}\right]_{\mu=0,x=0} = -1$$

$$\left[\frac{\partial^2 f}{\partial x^2}\right]_{\mu=o,x=0} < 0$$

$$\left[\frac{\partial^3 f}{\partial x^3}\right]_{\mu=0,x=0} < 0.$$

Then there are intervals $(\mu_1, 0)$, $(0, \mu_2)$, and $\varepsilon > 0$ such that

1. If $\mu \in (0, \mu_2)$, then $f_\mu(x)$ has one unstable fixed point and one stable orbit of period two for $x \in (-\epsilon, \epsilon)$, and
2. If $\mu \in (\mu_{1,0})$, then $f_\mu(x)$ has a single stable fixed point for $x \in (-\epsilon, \epsilon)$.

This type of BIFURCATION is known as a flip bifurcation. An example of an equation displaying a flip bifurcation is

$$f(x) = \mu - x - x^2.$$

Floor

FLOOR FUNCTION

Floor Function

The function floor function $\lfloor x \rfloor$, also called the greatest integer function, gives the largest INTEGER less than or equal to x. In many computer languages, the floor function is called the INTEGER PART function and is denoted `int(x)`. The name and symbol for the floor function were coined by K. E. Iverson (Graham *et al.* 1990).

Unfortunately, in many older and current works (e.g., Steinhaus 1983, p. 300; Shanks 1993; Ribenboim 1996; Hilbert and Cohn-Vossen 1999, p. 38; Hardy 1999, p. 18), the symbol $[x]$ is used instead of $\lfloor x \rfloor$ (Graham *et al.* 1990, p. 67). Because of the elegant symmetry of the floor function and CEILING FUNCTION symbols $\lfloor x \rfloor$ and $\lceil x \rceil$, and because $[x]$ is such a useful symbol when interpreted as an IVERSON BRACKET, the use of $[x]$ to denote the floor function should be deprecated. In this work, the symbol $[x]$ is used to denote the NEAREST INTEGER FUNCTION since it naturally falls between the $\lfloor x \rfloor$ and $\lceil x \rceil$ symbols.

Since usage concerning fractional part/value and integer part/value can be confusing, the following table gives a summary of names and notations used (D. W. Cantrell). Here, S&O indicates Spanier and Oldham (1987).

notation	name	S&O	Graham *et al.*	*Mathematica*
$\lfloor x \rfloor$	integer-value	Int(x)	floor or integer part	`Floor[x]`
$\mathrm{sgn}(x)\lfloor \lvert x\rvert \rfloor$	integer-part	Ip(x)	no name	`IntegerPart[x]`
$x - \lfloor x \rfloor$	fractional-value	frac(x)	fractional part or $\{x\}$	no name
$\mathrm{sgn}(x)(\lvert x\rvert - \lfloor \lvert x\rvert \rfloor)$	fractional-part	$\mathrm{F_p}(x)$	no name	`FractionalPart[x]`

There are infinitely many integers OF THE FORM $\lfloor (3/2)^n \rfloor$ and $\lfloor (4/3)^n \rfloor$ which are composite, where $\lfloor x \rfloor$ is the FLOOR FUNCTION (Forman and Shapiro, 1967; Guy 1994, p. 220). The first few composite $\lfloor (3/2)^n \rfloor$ occur for $n = 8$, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 23, ... (Sloane's A046037), and the few composite $\lfloor (4/3)^n \rfloor$ occur for $n = 5$, 8, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, ... (Sloane's A046038). Numbers OF THE FORM frac($(3/2)^n$), where frac(x) is the FRACTIONAL PART also appear in WARING'S PROBLEM.

Floquet Analysis

Given a system of periodic ORDINARY DIFFERENTIAL EQUATIONS OF THE FORM

$$\frac{d}{dt}\begin{bmatrix} x \\ y \\ v_x \\ v_y \end{bmatrix} = -\begin{bmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \\ \Phi_{xx} & \Phi_{yy} & 0 & 0 \\ \Phi_{xy} & \Phi_{yy} & 0 & 0 \end{bmatrix}\begin{bmatrix} x \\ y \\ v_x \\ v_y \end{bmatrix}, \tag{1}$$

the solution can be written as a LINEAR COMBINATION of functions OF THE FORM

$$\begin{bmatrix} x(t) \\ y(t) \\ v_x \\ v_y \end{bmatrix} = \begin{bmatrix} x_0 \\ y_0 \\ v_{x0} \\ v_{y0} \end{bmatrix} e^{\mu t} P_\mu(t), \tag{2}$$

where $P_\mu(t)$ is a function periodic with the same period T as the equations themselves. Given an ORDINARY DIFFERENTIAL EQUATION OF THE FORM

$$\ddot{x} + g(t)x = 0, \tag{3}$$

where $g(t)$ is periodic with period T, the ODE has a pair of independent solutions given by the REAL and IMAGINARY PARTS of

$$x + w(t)e^{i\psi(t)} \tag{4}$$

$$\dot{x} = (\dot{w} + iw\dot{\psi})e^{i\psi} \tag{5}$$

$$\ddot{x} = \left[\ddot{w} + i\dot{w}\dot{\psi} + i(\dot{w}\dot{\psi} + w\ddot{\psi} + iw\dot{\psi}^2)\right]e^{i\psi}$$
$$= \left[(\ddot{w} - w\dot{\psi}^2) + i(2\dot{w}\dot{\psi} + w\ddot{\psi})\right]e^{i\psi.} \tag{6}$$

Plugging these into (3) gives

$$\ddot{w} + 2i\dot{w}\dot{\psi} + w(g + i\ddot{\psi} - \dot{\psi}^2) = 0, \tag{7}$$

so the REAL and IMAGINARY PARTS are

$$\ddot{w} + w(g - \dot{\psi}^2) = 0 \tag{8}$$

$$2\dot{w}\dot{\psi} + w\ddot{\psi} = 0. \tag{9}$$

From (9),

$$\frac{2\dot{w}}{w} + \frac{\ddot{\psi}}{\dot{\psi}} = 2\frac{d}{dt}(\ln w) + \frac{d}{dt}[\ln(\dot{\psi})]$$
$$= \frac{d}{dt}\ln(\dot{\psi}w^2) = 0. \tag{10}$$

Integrating gives

$$\dot{\psi} = \frac{c}{w^2}, \tag{11}$$

where C is a constant which must equal 1, so ψ is given by

$$\psi = \int_{to}^{t} \frac{dt}{w^2}. \tag{12}$$

The REAL solution is then

$$x(t) = w(t)\cos[\psi(t)], \tag{13}$$

so

$$\dot{x} = \dot{w}\cos\psi - w\dot{\psi}\sin\psi = \dot{w}\frac{x}{w} - w\dot{\psi}\sin\psi$$
$$= \dot{w}\frac{x}{w} - w\frac{1}{w^2}\sin\psi = \dot{w}\frac{x}{w} - \frac{1}{w}\sin\psi \tag{14}$$

and

$$1 = \cos^2\psi + \sin^2\psi = x^2w^{-2} + \left[w\left(\dot{w}\frac{x}{w} - \dot{x}\right)\right]^2$$
$$= x^2w^{-2} + (\dot{w}x - w\dot{x})^2 \equiv i(x, \dot{x}, t), \tag{15}$$

which is an integral of motion. Therefore, although $w(t)$ is not explicitly known, an integral I always exists. Plugging (10) into (8) gives

$$\ddot{w} + g(t)w - \frac{1}{w^3} = 0, \tag{16}$$

which, however, is not any easier to solve than (3).

Floquet's Theorem

Let $Q(x)$ be a real or complex piecewise-continuous function of the real variable x defined for all values of x that is periodic with minimum period π so that

$$Q(x+\pi)=Q(x). \tag{1}$$

Then the differential equation

$$y^n+Q(x)y=0 \tag{2}$$

has two continuously differentiable solutions $y_1(x)$ and $y_2(x)$, and the characteristic equation is

$$\rho^2-[y_1(\pi)+y_2'(\pi)]\rho+1=0, \tag{3}$$

with eigenvalues $\rho_1=e^{i\alpha\pi}$ and $\rho_2=e^{-i\alpha\pi}$. The Floquet's theorem states that if the roots ρ_1 and ρ_2 are different from each other, then (2) has two linearly independent solutions

$$f_1(x)=e^{i\alpha x}p_1(x) \tag{4}$$

$$f_2(x)=e^{-i\alpha x}p_2(x), \tag{5}$$

where $p_1(x)$ and $p_2(x)$ are period with period π (Magnus and Winkler 1979, p. 4).

Flype

flype

A 180° rotation of a TANGLE. The word "flype" is derived from the old Scottish verb meaning "to turn or fold back." Tait (1898) used this word to indicate a different knot transformation than the one understood in the modern definition, illustrated above (Hoste *et al.* 1998).

Flyping Conjecture

Also called the TAIT FLYPING CONJECTURE. Given two reduced alternating projections of the same KNOT, they are equivalent on the SPHERE IFF they are related by a series of FLYPES. The conjecture was proved by Menasco and Thistlethwaite (1991, 1993) using properties of the JONES POLYNOMIAL. It allows all possible REDUCED alternating projections of a given ALTERNATING KNOT to be drawn.

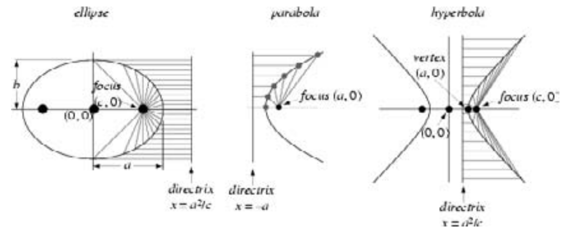
The following table gives properties of different types of conic sections, where k is the



Focal Parameter

The distance p (sometimes also denoted k) from the FOCUS to the DIRECTRIX of a CONIC SECTION. The following table gives the focal parameter for the different types of conics, where a is the SEMIMAJOR AXIS, c is the distances from the origin to the FOCUS, and e is the ECCENTRICITY.

conic	e	$p(a,b)$	$p(a,c)$	$p(a,e)$
ELLIPSE	$0<e<1$	$\frac{b^2}{\sqrt{a^2-b^2}}$	$\frac{a^2-c^2}{c}$	$\frac{a(1-e^2)}{e}$
PARABOLA	$e=1$	$2a$	$2a$	$2a$
HYPERBOLA	$e>1$	$\frac{b^2}{\sqrt{a^2+b^2}}$	$\frac{c^2-a^2}{c}$	$\frac{a(e^2-1)}{e}$

See also CONIC SECTION, DIRECTRIX (CONIC SECTION), ECCENTRICITY, FOCUS

Focus

A point related to the construction and properties of CONIC SECTIONS. HYPERBOLAS and noncircular ELLIPSES have two distinct foci and two associated DIRECTRICES, each DIRECTRIX being PERPENDICULAR to the line joining the two foci (Eves 1965, p. 275).

Foias Constant

A problem listed in a fall issue of *Gazeta Matematica* in the mid-1970s posed the question if $x_1 > 0$ and

$$x_{n+1} = \left(1 + \frac{1}{x_n}\right)^n \tag{1}$$

for $n = 1, 2, ...$, then are there any values for which $x_n \to \infty$? The problem, listed as one given on an entrance exam to prospective freshman in the mathematics department at the University of Bucharest, was solved by C. Foias.

It turns out that there exists exactly one real number

$$\alpha \approx 1.187452351126501 \tag{2}$$

such that if $x_1 = \alpha$, then $x_n \to \infty$. However, no analytic form is known for this constant, either as the root of a function or as a combination of other constants. Moreover, in this case,

$$\lim_{n\to\infty} x_n \frac{\ln n}{n} = 1, \quad (3)$$

which can be rewritten as

$$\lim_{n\to\infty} \frac{x_n}{\pi(n)} = 1, \quad (4)$$

where $\pi(n)$ is the PRIME COUNTING FUNCTION. However, Ewing and Foias (2000) believe that this connection with the PRIME NUMBER THEOREM is fortuitous.

Foias also discovered that the problem stated in the journal was a misprint of the actual exam problem, which used the recurrence $x_{n+1} = (1 + 1/x_n)^{x_n}$ (Ewing and Foias 2000). In this form, the recurrence converges to

$$x_\infty \approx 2.293166287411861031508028291250 8 \quad (5)$$

for all starting values of x_1, which is simply the root of

$$x = \left(1 + \frac{1}{x}\right)^x. \quad (6)$$

Fold Bifurcation

Let $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be a one-parameter family of C^2 MAP satisfying

$$f(0,0) = 0$$

$$\left[\frac{\partial f}{\partial x}\right]_{\mu=0,x=0} = 0$$

$$\left[\frac{\partial^2 f}{\partial x^2}\right]_{\mu=0,x=0} > 0$$

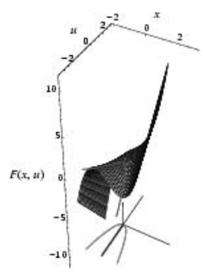
$$\left[\frac{\partial f}{\partial \mu}\right]_{\mu=0,x=0} > 0,$$

then there exist intervals $(\mu_1, 0)$, $(0, \mu_2)$ and $\varepsilon > 0$ such that

1. If $\mu \in (\mu_1, 0)$, then $f_\mu(x)$ has two fixed points in $(-\epsilon, \epsilon)$ with the positive one being unstable and the negative one stable, and
2. If $\mu \in (0, \mu_2)$, then $f_\mu(x)$ has no fixed points in $(-\epsilon, \epsilon)$.

This type of BIFURCATION is known as a fold bifurcation, sometimes also called a SADDLE-NODE BIFURCATION or TANGENT BIFURCATION. An example of an equation displaying a fold bifurcation is

$$\dot{x} = \mu - x^2$$



(Guckenheimer and Holmes 1997, p. 145).

Folding

The points accessible from c by a single fold which leaves a_1, ..., a_n fixed are exactly those points interior to or on the boundary of the intersection of the CIRCLES through c with centers at a_i, for $i = 1, ..., n$. Given any three points in the plane a, b, and c, there is an EQUILATERAL TRIANGLE with VERTICES x, y, and z for which a, b, and c are the images of x, y, and z under a single fold.

Given any four points in the plane a, b, c, and d, there is some SQUARE with VERTICES x, y, z, and w for which a, b, c, and d are the images of x, y, z, and w under a sequence of at most three folds. In addition, any four collinear points are the images of the VERTICES of a suitable SQUARE under at most two folds. Every five (six) points are the images of the VERTICES of suitable regular PENTAGON (HEXAGON) under at most five (six) folds. Wells (1991) illustrates a PENTAGON, HEXAGON, HEPTAGON, and OCTAGON constructed using paper folding.

The least number of folds required for $n \geq 4$ is not known, but some bounds are. In particular, every set of n points is the image of a suitable REGULAR n-gon under at most $F(n)$ folds, where

$$F(n) \leq \begin{cases} \frac{1}{2}(3n-2) & \text{for } n \text{ even} \\ \frac{1}{2}(3n-3) & \text{for } n \text{ odd.} \end{cases}$$

The first few values are 0, 2, 3, 5, 6, 8, 9, 11, 12, 14, 15, 17, 18, 20, 21, ... (Sloane's A007494).

Foliation

Let M^n be an n-MANIFOLD and let $\mathrm{F} = \{F_\alpha\}$ denote a PARTITION of M^n into DISJOINT path-connected SUBSETS. Then F is called a foliation of M^n of codimension c (with $0 < c < n$) if there exists a COVER of M^n by OPEN SETS U, each equipped with a HOMEOMORPHISM $h : U \to \mathbb{R}^n$ or $h : U \to \mathbb{R}^n_+$ which throws each nonempty component of $F_\alpha \cap U$ onto a parallel translation of the standard HYPERPLANE $\mathbb{R}^{n-c}$ in $\mathbb{R}^n$. Each F_α is then called a LEAF and is not necessarily closed or compact.

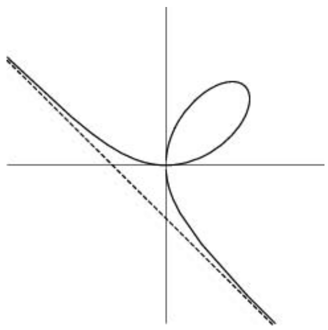
Folium

The word "folium" means leaf-shaped. The polar equation is

$$r = \cos\theta(4a\sin^2\theta - b).$$

If $b \geq 4a$, it is a single folium. If $b = 0$, it is a BIFOLIUM. If $0 < b < 4a$, it is a TRIFOLIUM. The simple folium is the PEDAL CURVE of the DELTOID where the PEDAL POINT is one of the CUSPS.



See also BIFOLIUM, FOLIUM OF DESCARTES, KEPLER'S FOLIUM, QUADRIFOLIUM, ROSE, TRIFOLIUM

References

Lawrence, J. D. *A Catalog of Special Plane Curves.* New York: Dover, pp. 152–53, 1972.

MacTutor History of Mathematics Archive. "Folium." http://www-groups.dcs.st-and.ac.uk/~history/Curves/Folium.html.

Folium of Descartes

A plane curve proposed by Descartes to challenge Fermat's extremum-finding techniques. In parametric form,

$$x = \frac{3at}{1+t^3} \tag{1}$$

$$y = \frac{3at^2}{1+t^3}. \tag{2}$$

The curve has a discontinuity at $t = -1$. The left wing is generated as t runs from -1 to 0, the loop as t runs from 0 to ∞, and the right wing as t runs from $-\infty$ to -1.

The CURVATURE and TANGENTIAL ANGLE of the folium of Descartes, illustrated above, are

$$\kappa(t) = \frac{2(1+t^3)^4}{3(1+4t^2-4t^3-4t^5+4t^6+t^8)^{3/2}} \tag{3}$$

$$\phi(t) = \frac{1}{2}\left[\pi + \tan^{-1}\left(\frac{1-2t^3}{t^4-2t}\right) - \tan^{-1}\left(\frac{2t^3-1}{t^4-2t}\right)\right].$$

$$17 + 4\sqrt{18} \tag{4}$$

Converting the PARAMETRIC EQUATIONS to POLAR COORDINATES gives

$$r^2 = \frac{(3at)^2(1+t^2)}{(1+t^3)^2} \tag{5}$$

$$\theta = \tan^{-1}\left(\frac{y}{x}\right) = \tan^{-1} t, \tag{6}$$

so

$$d\theta = \frac{dt}{1+t^2}. \tag{7}$$

The AREA enclosed by the curve is

$$A = \frac{1}{2}\int r^2\, d\theta = \frac{1}{2}\int_0^\infty \frac{(3at)^2(1+t^2)}{(1+t^3)^2}\frac{dt}{1+t^2}$$
$$= \frac{3}{2}a^2\int_0^\infty \frac{3t^2 dt}{(1+t^3)^2}. \tag{8}$$

Now let $u \equiv 1 + t^3$ so $du = 3t^2 dt$

$$A = \frac{3}{2}a^2\int_1^\infty \frac{du}{u^2} = \frac{3}{2}a^2\left[-\frac{1}{u}\right]_1^\infty = \frac{3}{2}a^2(-0+1) = \frac{3}{2}a^2 \tag{9}$$

In CARTESIAN COORDINATES,

$$x^3 + y^3 = \frac{(3at)^3(1+t^3)}{(1+t^3)^3} = \frac{(3at)^3}{(1+t^3)^2} = 3axy \tag{10}$$

(MacTutor Archive). The equation of the ASYMPTOTE is

$$y = -a - x. \tag{11}$$

Follows

SUCCEEDS

Fontené Theorems

1. If the sides of the PEDAL TRIANGLE of a point P meet the corresponding sides of a TRIANGLE $\Delta O_1O_2O_3$ at X_1, X_2, and X_3, respectively, then P_1X_1, P_2X_2, P_3X_3 meet at a point L common to the CIRCLES $O_1O_2O_3$ and $P_1P_2P_3$. In other words, L is one of the intersections of the NINE-POINT CIRCLE of $A_1A_2A_3$ and the PEDAL CIRCLE of P.
2. If a point moves on a fixed line through the CIRCUMCENTER, then its PEDAL CIRCLE passes through a fixed point on the NINE-POINT CIRCLE.
3. The PEDAL CIRCLE of a point is tangent to the NINE-POINT CIRCLE IFF the point and its ISOGONAL CONJUGATE lie on a LINE through the ORTHOCENTER. FEUERBACH'S THEOREM is a special case of this theorem.

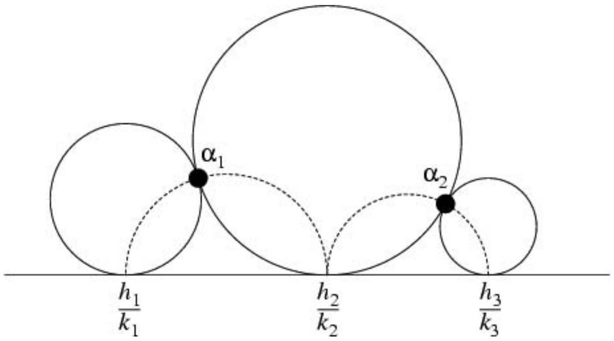
Ford Circle

Pick any two INTEGERS h and k, then the CIRCLE $C(h,\ k)$ of RADIUS $1/(2k^2)$ centered at $(h/k, \pm 1/(2k^2))$ is known as a Ford circle. No matter what and how many hs and ks are picked, none of the Ford circles intersect (and all are tangent to the X-AXIS). This can be seen by examining the squared distance between the centers of the circles with $(h,\ k)$ and (h', k'),

$$d^2 = \left(\frac{h'}{k'} - \frac{h}{k}\right)^2 + \left(\frac{1}{2k'^2} - \frac{1}{2k^2}\right)^2. \tag{1}$$

Let s be the sum of the radii



$$s = r_1 + r_2 = \frac{1}{2k^2} + \frac{1}{2k'^2}, \tag{2}$$

then

$$d^2 - s^2 = \frac{(h'k - hk')^2 - 1}{k^2k'^2}. \tag{3}$$

But $(h'k - k'h)^2 \geq 1$, so $d^2 - s^2 \geq 0$ and the distance between circle centers is $\geq$ the sum of the CIRCLE RADII, with equality (and therefore tangency) IFF $|h'k - k'h| = 1$. Ford circles are related to the FAREY

SEQUENCE (Conway and Guy 1996).

If h_1/k_1, h_2/k_2, and h_3/k_3 are three consecutive terms in a FAREY SEQUENCE, then the circles $c(h_1, k_1)$ and $c(h_2, k_2)$ are tangent at

$$\alpha_1 = \left(\frac{h_2}{k_2} - \frac{k_1}{k_2(k_2^2 + k_1^2)}, \frac{1}{k_2^2 + k_1^2}\right) \tag{4}$$

and the circles $c(h_2, k_2)$ and $C(h_3, k_3)$ intersect in

$$\alpha_2 = \left(\frac{h_2}{k_2} - \frac{k_3}{k_2(k_2^2 + k_3^2)}, \frac{1}{k_2^2 + k_3^2}\right). \tag{5}$$

Moreover, α_1 lies on the circumference of the SEMICIRCLE with diameter $(h_1/k_1, 0) - (h_2/k_2, 0)$ and α_2 lies on the circumference of the SEMICIRCLE with diameter $(h_2/k_2, 0) - (h_3/k_3, 0)$ (Apostol 1997, p. 101).

Forest

An acyclic graph (i.e., a GRAPH without any CIRCUITS). Forests therefore consist only of (possibly disconnected) TREES, hence the name "forest." A forest with k components and n nodes has $n-k$ EDGES. The numbers of forests on $n = 1, 2, ...$ nodes are 1, 2, 3, 6, 10, 20, 37, ... (Sloane's A005195). A graph can be tested to determine if it is acyclic using `AcylicQ[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

CONNECTED forests are TREES.

Fortunate Prime

Let

$$X_k \equiv 1 + p_k\#,$$

where p_k is the kth PRIME and p is the PRIMORIAL, and let q_k be the NEXT PRIME (i.e., the smallest PRIME greater than X_k),

$$q_k = p_{1+\pi}(x_k) = p_{1+\pi(1+p_k\#)}$$

where $\pi(n)$ is the PRIME COUNTING FUNCTION. Then R. F. Fortune conjectured that $F_k \equiv q_k - X_k + 1$ is PRIME for all k. The first values of F_k are 3, 5, 7, 13, 23, 17, 19, 23, ... (Sloane's A005235), and all known values of F_k are indeed PRIME (Guy 1994). The indices of these primes are 2, 3, 4, 6, 9, 7, 8, 9, 12, 18, ... In numerical order with duplicates removed, the Fortunate primes are 3, 5, 7, 13, 17, 19, 23, 37, 47, 59, 61, 67, 71, 79, 89, ... (Sloane's A046066).

Forward Difference

The forward difference is a FINITE DIFFERENCE defined by

$$\Delta a_n \equiv a_{n+1} - a_n. \tag{1}$$

Higher order differences are obtained by repeated operations of the forward difference operator,

$$\Delta^k a_n = \Delta^{k-1} a_{n+1} - \Delta^{k-1} a_n, \tag{2}$$

so

$$\Delta^2 a_n = \Delta_n^2 = \Delta(\Delta_n) = \Delta(a_{n+1} - a_n)$$
$$= \Delta_{n+1} - \Delta_n = a_{n+2} - 2a_{n+1} + a_n. \tag{3}$$

In general,

$$\Delta_n^k \equiv \Delta^k a_n \equiv \sum_{i=0}^{k} (-1)^i \binom{k}{i} a_{n+k-i}, \tag{4}$$

where $\binom{k}{m}$ is a BINOMIAL COEFFICIENT (Sloane and Plouffe 1985, p. 10).

NEWTON'S FORWARD DIFFERENCE FORMULA expresses a_n as the sum of the nth forward differences

$$a_n = a_0 + n\Delta_0 + \frac{1}{2!} n(n+1)\Delta_0^2 + \frac{1}{3!} n(n+1)(n+2)\Delta_0^3 + \ldots \tag{5}$$

where Δ_0^n is the first nth difference computed from the difference table. Furthermore, if the differences a_m, Δa_m, $\Delta^2 a_m$, ..., are known for some fixed value of m, then a formula for the nth term is given by

$$a_{n+m} = \sum_{k=0}^{n} \binom{n}{k} \Delta^k a_m \tag{6}$$

(Sloane and Plouffe 1985, p. 10).

Four Dog Problem

MICE PROBLEM

Four Exponentials Conjecture

Let x_1 and x_2 be two linearly independent complex numbers, and let y_1 and y_2 be two linearly independent complex numbers. Then the four exponential conjecture posits that at least one of

$$e^{x_1 y_1}, e^{x_1 y_2}, e^{x_2 y_1}, e^{x_2 y_2}$$

is TRANSCENDENTAL (Waldschmidt 1979, p. 3.5). The corresponding statement obtained by replacing y_1, y_2 with y_1, y_2, y_3 has been proven and is known as the SIX EXPONENTIALS THEOREM.

Four Travelers Problem

Let four LINES in a PLANE represent four roads in GENERAL POSITION, and let one traveler T_i be walking along each road at a constant (but not necessarily equal to any other traveler's) speed. Say that two travelers T_i and T_j have "met" if they were simultaneously at the intersection of their two roads. Then if T_1 has met all other three travelers (T_2, T_3, and T_4) and T_2, in addition to meeting T_1, has met T_3 and T_4, then T_3 and T_4 have also met!

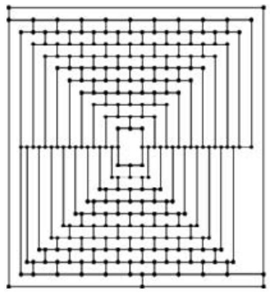
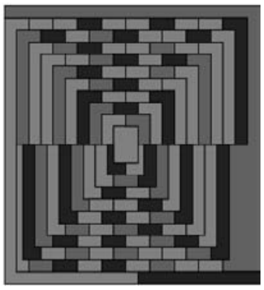
Four-Bug Problem

MICE PROBLEM

Four-Color Problem



FOUR-COLOR THEOREM



Four-Color Theorem

The four-color theorem states that any map in a PLANE can be colored using four-colors in such a way that regions sharing a common boundary (other than a single point) do not share the same color. This problem is sometimes also called GUTHRIE'S PROBLEM after F. Guthrie, who first conjectured the theorem in 1853. The CONJECTURE was then communicated to de Morgan and thence into the general community. In 1878, Cayley wrote the first paper on the conjecture.

Fallacious proofs were given independently by Kempe (1879) and Tait (1880). Kempe's proof was accepted for a decade until Heawood showed an error using a map with 18 faces (although a map with nine faces suffices to show the fallacy). The HEAWOOD CONJECTURE provided a very general assertion for map coloring, showing that in a GENUS 0 SPACE (i.e., either the SPHERE or PLANE), six colors suffice. This number can easily be reduced to five, but reducing the number of colors all the way to four proved very difficult. (The KLEIN BOTTLE is the sole exception to the HEAWOOD CONJECTURE, requiring five colors instead of the six expected for a surface of genus 0.)

Finally, Appel and Haken (1977) announced a computer-assisted proof that four colors were SUFFICIENT. However, because part of the proof consisted of an exhaustive analysis of many discrete cases by a computer, some mathematicians do not accept it. However, no flaws have yet been found, so the proof appears valid. A potentially independent proof has recently been constructed by N. Robertson, D. P. Sanders, P. D. Seymour, and R. Thomas.

Martin Gardner (1975) played an April Fool's joke by (incorrectly) claiming that the map of 110 regions illustrated above requires five colors and constitutes a counterexample to the four-color theorem. However, the coloring of Wagon (1998; 1999, pp. 535–36) clearly shows that this map is, in fact, four-colorable.

Four-Dimensional Geometry

4-DIMENSIONAL GEOMETRY

Fourier Analysis

FOURIER SERIES

Fourier Cosine Series

If $f(x)$ is an EVEN FUNCTION, then $b_n = 0$ and the FOURIER SERIES collapses to

$$f(x) = \frac{1}{2}a_0 + \sum_{n=1}^{\infty} a_n \cos(nx), \tag{1}$$

where

$$a_0 = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)dx = \frac{2}{\pi}\int_0^{\pi} f(x)dx \tag{2}$$

$$a_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\cos(nx)dx$$

$$= \frac{2}{\pi}\int_0^{\pi} f(x)\cos(nx)dx \tag{3}$$

where the last equality is true because

$$f(x)\cos(nx) = f(-x)\cos(-nx) \tag{4}$$

Letting the range go to L,

$$a_0 = \frac{2}{L}\int_0^L f(x)dx \tag{5}$$

$$a_n = \frac{2}{L}\int_0^L f(x)\cos\left(\frac{n\pi x}{L}\right)dx. \tag{6}$$

See also EVEN FUNCTION, FOURIER COSINE TRANSFORM, FOURIER SERIES, FOURIER SINE SERIES

Fourier Cosine Transform

The Fourier cosine transform is the REAL PART of the full complex FOURIER TRANSFORM,

$$\mathcal{F}_c[f(x)] = \Re[\mathcal{F}[f(x)]].$$

In *Mathematica* 4.0, the Fourier cosine transform $F_c(k)$ of a function $f(x)$ is implemented as `FourierCosTransform`[f, x, k], and different choices of a and b can be used by passing the optional `FourierParameters->`$\{a, b\}$ option. In this work, $a = 0$ and $b = -2\pi$.

In version 4.1, the discrete Fourier cosine transform of a list l of real numbers can be computed using `FourierCos`[l] in the *Mathematica* add-on package `LinearAlgebra‘FourierTrig‘` (which can be loaded with the command `<<LinearAlgebra‘`).

Fourier Integral

FOURIER TRANSFORM

Fourier Matrix

The $n \times n$ SQUARE MATRIX F_n with entries given by

$$F_{jk} = e^{2\pi ijk/n} \equiv \omega^{jk} \quad (1)$$

for $j, k = 0, 1, 2, \ldots, n-1$, where i is the IMAGINARY NUMBER $i = \sqrt{-1}$, and normalized by $1\sqrt{n}$ to make it a UNITARY. The Fourier matrix F_2 is given by

$$\mathsf{F}_2 = \frac{1}{\sqrt{2}}\begin{bmatrix} 1 & 1 \\ 1 & i^2 \end{bmatrix}, \quad (2)$$

and the F_4 matrix by

$$\mathsf{F}_4 = \frac{1}{\sqrt{4}}\begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & i & i^2 & i^3 \\ 1 & i^2 & i^4 & i^6 \\ 1 & i^3 & i^6 & i^9 \end{bmatrix}$$

$$= \frac{1}{2}\begin{bmatrix} 1 & & 1 & \\ & 1 & & i \\ 1 & & -1 & \\ & 1 & & -i \end{bmatrix}\begin{bmatrix} 1 & 1 & & \\ 1 & i^2 & & \\ & & 1 & 1 \\ & & 1 & i^2 \end{bmatrix}\begin{bmatrix} 1 & & & \\ & & 1 & \\ & 1 & & \\ & & & 1 \end{bmatrix}. \quad (3)$$

In general,

$$\mathsf{F}_{2n} = \begin{bmatrix} \mathsf{I}_n & \mathsf{D}_n \\ \mathsf{I}_n & -\mathsf{D}_n \end{bmatrix}\begin{bmatrix} \mathsf{F}_n & \\ & \mathsf{F}_n \end{bmatrix}\begin{bmatrix} \text{even-odd} \\ \text{shuffle} \end{bmatrix}, \quad (4)$$

with

$$\begin{bmatrix} \mathsf{F}_n & \\ & \mathsf{F}_n \end{bmatrix} = \begin{bmatrix} \mathsf{I}_{n/2} & \mathsf{D}_{n/2} & & \\ \mathsf{I}_{n/2} & -\mathsf{D}_{n/2} & & \\ & & \mathsf{I}_{n/2} & \mathsf{D}_{n/2} \\ & & \mathsf{I}_{n/2} & -\mathsf{D}_{n/2} \end{bmatrix} \times \begin{bmatrix} \mathsf{F}_{n/2} & & & \\ & \mathsf{F}_{n/2} & & \\ & & \mathsf{F}_{n/2} & \\ & & & \mathsf{F}_{n/2} \end{bmatrix}\begin{bmatrix} \text{even-odd} \\ 0, 2(\text{mod}4) \\ \text{even-odd} \\ 1, 3(\text{mod}4) \end{bmatrix}, \quad (5)$$

where I_n is the $n \times n$ IDENTITY MATRIX and D_n is the DIAGONAL MATRIX with entries 1, ω, ..., ω^{n-1}. Note that the factorization (which is the basis of the FAST FOURIER TRANSFORM) has two copies of F_2 in the center factor MATRIX.

Fourier Series

Fourier series are expansions of PERIODIC FUNCTIONS $f(x)$ in terms of an infinite sum of SINES and COSINES OF THE FORM

$$f(x) = \sum_{n=0}^{\infty} a'_n \cos(nx) + \sum_{n=0}^{\infty} b'_n \sin(nx). \quad (1)$$

Fourier series make use of the ORTHOGONALITY relationships of the SINE and COSINE functions, which can be used to calculate the coefficients a_n and b_n in the sum. The computation and study of Fourier series is known as HARMONIC ANALYSIS.

To compute a Fourier series, use the integral identities

$$\int_{-\pi}^{\pi} \sin(mx)\sin(nx)dx = \pi\delta_{mn} \quad \text{for } n, m \neq 0 \quad (2)$$

$$\int_{-\pi}^{\pi} \cos(mx)\cos(nx)dx = \pi\delta_{mn} \quad \text{for } n, m \neq 0 \quad (3)$$

$$\int_{-\pi}^{\pi} \sin(mx)\cos(nx)dx = 0 \quad (4)$$

$$\int_{-\pi}^{\pi} \sin(mx)dx = 0 \quad (5)$$

$$\int_{-\pi}^{\pi} \cos(mx)dx = 0, \quad (6)$$

where δ_{mn} is the KRONECKER DELTA. Now, expand your function $f(x)$ as an infinite series OF THE FORM

$$f(x) = \sum_{n=0}^{\infty} a_n' \cos(nx) + \sum_{n=0}^{\infty} b_n' \sin(nx)$$

$$= \frac{1}{2}a_0 + \sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx) \quad (7)$$

where we have relabeled the $a_0 = 2a_0'$ term for future convenience but set $b_n = b_n'$ and left $a_n = a_n'$ for $n \geq 1$. Assume the function is periodic in the interval $[-\pi, \pi]$. Now use the orthogonality conditions to obtain

$$\int_{-\pi}^{\pi} f(x)dx$$

$$= \int_{-\pi}^{\pi} \left[\sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx) + \frac{1}{2}a_0\right] dx$$

$$= \sum_{n=1}^{\infty} \int_{-\pi}^{\pi} [a_n \cos(nx) + b_n \sin(nx)]dx + \frac{1}{2}a_0 \int_{-\pi}^{\pi} dx$$

$$= \sum_{n=1}^{\infty} (0+0) + \pi a_0 = \pi a_0 \quad (8)$$

and

$$\int_{-\pi}^{\pi} f(x) \sin(mx)dx$$

$$= \int_{-\pi}^{\pi} \left[\sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx) + \frac{1}{2}a_0\right] \times \sin(mx)dx$$

$$= \sum_{n=1}^{\infty} \int_{-\pi}^{\pi} [a_n \cos(nx) \sin(mx) + b_n \sin(nx) \sin(mx)]dx + \frac{1}{2}a_0 \int_{-\pi}^{\pi} \sin(mx)dx$$

$$= \sum_{n=1}^{\infty} (0 + b_n \pi \delta_{mn}) + 0 = \pi b_n, \quad (9)$$

so

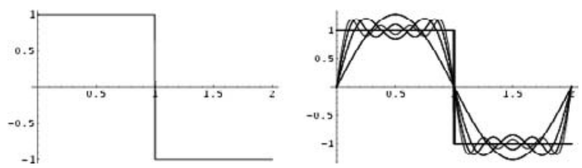
$$\int_{-\pi}^{\pi} f(x) \cos(mx)dx = \int_{-\pi}^{\pi} \left[\sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx) + \frac{1}{2}a_0\right] \cos(mx)dx$$

$$= \sum_{n=1}^{\infty} \int_{-\pi}^{\pi} [a_n \cos(nx) \cos(mx) + b_n \sin(nx) \cos(mx)]dx + \frac{1}{2}a_0 \int_{-\pi}^{\pi} \cos(mx)dx$$

$$= \sum_{n=1}^{\infty} (a_n \pi \delta_{mn} + 0) + 0 = \pi a_n. \quad (10)$$

Plugging back into the original series then gives

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x)dx \quad (11)$$



$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos(nx)dx \quad (12)$$

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin(nx)dx \quad (13)$$

for $n = 1, 2, 3, \ldots$. The series expansion converges to the function $\bar{f}$ (equal to the original function at points of continuity or to the average of the two limits at points of discontinuity)

$$\bar{f} \equiv \begin{cases} \frac{1}{2}\left[\lim_{x \to x_0-} f(x) + \lim_{x \to x_0+} f(x)\right] & \text{for } -\pi < x_0 < \pi \\ \frac{1}{2}\left[\lim_{x \to \pi^+} f(x) + \lim_{x \to \pi^-} f(x)\right] & \text{for } x_0 = -\pi, \pi \end{cases} \quad (14)$$

if the function satisfies the DIRICHLET CONDITIONS.

Near points of discontinuity, a "ringing" known as the GIBBS PHENOMENON, illustrated above, occurs. For a function $f(x)$ periodic on an interval $[-L, L]$, use a change of variables to transform the interval of integration to $[-1, 1]$. Let

$$x \equiv \frac{\pi x'}{L} \quad (15)$$

$$dx = \frac{\pi\, dx'}{L}. \quad (16)$$

Solving for x', $x' = Lx/\pi$. Plugging this in gives

$$f(x') = \tfrac{1}{2}a_0 + \sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x'}{L}\right) + \sum_{n=1}^{\infty} b_n \sin\left(\frac{n\pi x'}{L}\right) \quad (17)$$

$$\begin{cases} a_0 = \frac{1}{L} \int_{-L}^{L} f(x')\, dx' \\ a_n = \frac{1}{L} \int_{-L}^{L} f(x') \cos\left(\frac{n\pi x'}{L}\right) dx' \\ b_n = \frac{1}{L} \int_{-L}^{L} f(x') \sin\left(\frac{n\pi x'}{L}\right) dx' \end{cases} \quad (18)$$

If a function is EVEN so that $f(x)=f(-x)$, then $f(x)\sin(nx)$ is ODD. (This follows since $\sin(nx)$ is ODD and an EVEN FUNCTION times an ODD FUNCTION is an ODD FUNCTION.) Therefore, $b_n = 0$ for all n. Similarly, if a function is ODD so that $f(x)=-f(-x)$, then $f(x)\cos(nx)$ is ODD. (This follows since $\cos(nx)$ is EVEN and an EVEN FUNCTION times an ODD FUNCTION is an ODD FUNCTION.) Therefore, $a_n = 0$ for all n.

Because the SINES and COSINES form a COMPLETE ORTHOGONAL BASIS, the SUPERPOSITION PRINCIPLE holds, and the Fourier series of a LINEAR COMBINATION of two functions is the same as the LINEAR COMBINATION of the corresponding two series. The COEFFICIENTS for Fourier series expansions for a few common functions are given in Beyer (1987, pp. 411–12) and Byerly (1959, p. 51).

The notion of a Fourier series can also be extended to COMPLEX COEFFICIENTS. Consider a real-valued function $f(x)$. Write

$$f(x) = \sum_{n=-\infty}^{\infty} A_n e^{inx}. \tag{19}$$

Now examine

$$\int_{-\pi}^{\pi} f(x)e^{-imx}\,dx = \int_{-\pi}^{\pi}\left(\sum_{n=-\infty}^{\infty} A_n e^{inx}\right)e^{-imx}\,dx$$

$$= \sum_{n=-\infty}^{\infty} A_n \int_{-\pi}^{\pi} e^{i(n-m)x}\,dx$$

$$= \sum_{n=-\infty}^{\infty} A_n \int_{-\pi}^{\pi} \{\cos[(n-m)x] + i\sin[(n-m)x]\}\,dx$$

$$= \sum_{m=-\infty}^{\infty} A_n 2\pi\delta_{mn} = 2\pi A_m, \tag{20}$$

so

$$A_n = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(x)e^{-inx}\,dx. \tag{21}$$

The COEFFICIENTS can be expressed in terms of those in the FOURIER SERIES

$$A_n = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(x)[\cos(nx) - i\sin(nx)]\,dx$$

$$= \begin{cases} \frac{1}{2\pi}\int_{-\pi}^{\pi} f(x)[\cos(nx)+i\sin(nx)]\,dx & n<0 \\ \frac{1}{2\pi}\int_{-\pi}^{\pi} f(x)\,dx & n=0 \\ \frac{1}{2\pi}\int_{-\pi}^{\pi} f(x)[\cos(nx)-i\sin(nx)]\,dx & n>0 \end{cases}$$

$$= \begin{cases} \tfrac{1}{2}(a_n + ib_n) & \text{for } n<0 \\ \tfrac{1}{2}a_0 & \text{for } n=0 \\ \tfrac{1}{2}(a_n - ib_n) & \text{for } n>0 \end{cases} \tag{22}$$

For a function periodic in $[-L/2,\ L/2]$, these become

$$f(x) = \sum_{n=-\infty}^{\infty} A_n e^{i(2\pi nx/L)} \tag{23}$$

$$A_n = \frac{1}{L}\int_{-L/2}^{L/2} f(x)e^{-i(2\pi nx/L)}\,dx. \tag{24}$$

These equations are the basis for the extremely important FOURIER TRANSFORM, which is obtained by transforming A_n from a discrete variable to a continuous one as the length $L \to \infty$.

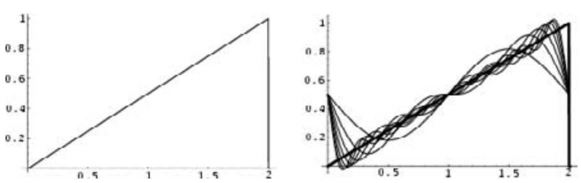
Fourier Series—Power Series

For $f(x)=x^k$ on the INTERVAL $[-L, L)$ and periodic with period $2L$, the FOURIER SERIES is given by

$$a_n=\frac{1}{L}\int_{-L}^{L} x^k \cos\left(\frac{n\pi x}{L}\right)\, dx$$



$$=\frac{2L^k}{1+k}\,{}_1F_2\left(\begin{matrix} & 1+\frac{1}{2}k \\ \frac{1}{2} & \frac{1}{2}(3+k)\end{matrix}; -\tfrac{1}{4}\pi^2 n^2\right)$$

$$b_n=\frac{1}{L}\int_{-L}^{L} x^k \sin\left(\frac{n\pi x}{L}\right)\, dx$$

$$=\frac{2n\pi L^k}{2+k}\,{}_1F_2\left(\begin{matrix} & 1+\frac{1}{2}k \\ \frac{3}{2} & 2+\frac{1}{2}k\end{matrix}; -\tfrac{1}{4}\pi^2 n^2\right),$$

where ${}_1F_2(a;\, b,\, c;\, x)$ is a generalized HYPERGEOMETRIC FUNCTION.

Fourier Series—Sawtooth Wave

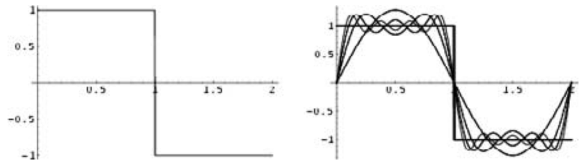
Consider a string of length $2L$ plucked at the right end, then

$$a_0=\frac{1}{L}\int_0^{2L}\frac{x}{2L}\,dx=\frac{1}{2L^2}\left[\tfrac{1}{2}x^2\right]_0^L=\frac{1}{4L^2}(2L)^2=1$$

$$a_n=\frac{1}{L}\int_0^{2L}\frac{x}{2L}\cos\left(\frac{n\pi x}{L}\right)dx$$

$$=\frac{[2n\pi\cos(n\pi)-\sin(n\pi)]\,\sin(n\pi)}{n^2\pi^2}=0$$

$$b_n=\frac{1}{L}\int_0^{2L}\frac{x}{2L}\sin\left(\frac{n\pi x}{L}\right)dx$$



$$=\frac{-2n\pi\cos(2n\pi)+\sin(2n\pi)}{2n^2\pi^2}=-\frac{1}{n\pi}.$$

The Fourier series is therefore

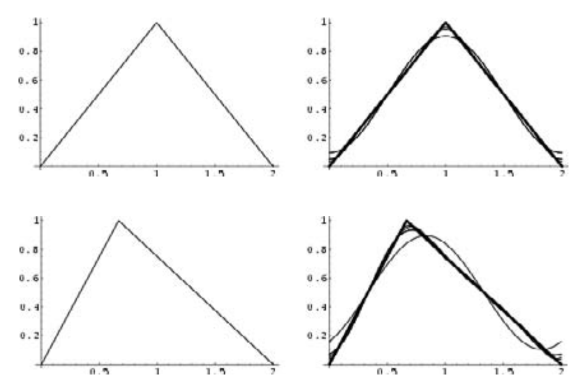
$$f(x)=\tfrac{1}{2}-\frac{1}{\pi}\sum_{n=1}^{\infty}\frac{1}{n}\sin\left(\frac{n\pi x}{L}\right).$$

See also FOURIER SERIES, FOURIER SERIES–SQUARE WAVE, SAWTOOTH WAVE

Fourier Series—Square Wave

Consider a square wave of length $2L$. Since the function is ODD, $a_0=a_n=0$, and

$$b_n=\frac{2}{L}\int_0^L \sin\left(\frac{n\pi x}{L}\right)\, dx$$



$$=\frac{4}{n\pi}\sin^2(\tfrac{1}{2}n\pi)=\frac{4}{n\pi}\begin{cases}0 & n\ \text{even}\\ 1 & n\ \text{odd}\end{cases}.$$

The Fourier series is therefore

$$f(x)=\frac{4}{\pi}\sum_{n=1,3,5,\ldots}^{\infty}\frac{1}{n}\sin\left(\frac{n\pi x}{L}\right).$$

See also FOURIER SERIES, FOURIER SERIES–SAWTOOTH WAVE, SQUARE WAVE

Fourier Series—Triangle

Let a string of length $2L$ have a y-displacement of unity when it is pinned an x-distance which is $((1/m))$ th of the way along the string. The displacement as a function of x is then

$$f_m(x)=\begin{cases}\dfrac{mx}{2L} & 0\le x\le\dfrac{2L}{m}\\[2ex] \dfrac{m}{1-m}\left(\dfrac{x}{2L}-1\right) & \dfrac{2L}{m}\le x\le 2L.\end{cases}$$

The COEFFICIENTS are therefore

$$a_0 = \frac{1}{L}\left[\int_0^{2L/m} \frac{nx}{2L}\,dx + \int_{2L/m}^{2L} \frac{n}{1-n}\left(\frac{x}{2L}-1\right)dx\right]$$

$$= 1$$

$$a_n = \frac{m\left[1 - m - \cos(2\pi n) + m\cos\left(\frac{2n\pi}{m}\right)\right]}{2(m-1)n^2\pi^2}$$

$$= \frac{m^2\left[\cos\left(\frac{2n\pi}{m}\right) - 1\right]}{2(m-1)m^2\pi^2}$$

$$b_n = \frac{m\left[m\sin\left(\frac{2\pi n}{m}\right) - \sin(2\pi n)\right]}{2(m-1)n^2\pi^2}$$

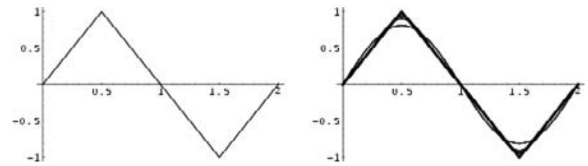
$$= \frac{m^2\sin\left(\frac{2\pi n}{m}\right)}{2(m-1)n^2\pi^2}.$$

The Fourier series is therefore

$$f_m(x) = \tfrac{1}{2} + \frac{m^2}{2(m-1)\pi^2} \times \sum_{n=1}^{\infty}\left\{\frac{1}{n^2}\left[\cos\left(\frac{2n\pi}{m}\right) - 1\right]\cos\left(\frac{n\pi x}{L}\right) + \frac{\sin\left(\frac{2\pi n}{m}\right)}{n^2}\sin\left(\frac{n\pi x}{L}\right)\right\}.$$

If $m = 2$, then a_n and b_n simplify to

$$a_n = -\frac{4}{n^2\pi^2}\sin^2\left(\tfrac{1}{2}n\pi\right) = -\frac{4}{n^2\pi^2}\begin{cases}0 & n = 0, 2, \ldots\\ 1 & n = 1, 3, \ldots\end{cases}$$



$$b_n = 0,$$

giving

$$f_2(x) = \tfrac{1}{2} - \frac{4}{\pi^2}\sum_{n=1,3,5,\ldots}^{\infty}\frac{1}{n^2}\cos\left(\frac{n\pi x}{L}\right).$$

See also FOURIER SERIES

Fourier Series—Triangle Wave

Consider a triangle wave of length $2L$. Since the function is ODD, $a_0 = a_n = 0$, and

$$b_n = \frac{2}{L}\left\{\int_0^{L/2}\frac{x}{L/2}\sin\left(\frac{n\pi x}{L}\right)dx + \int_{L/2}^{0}\left[1 - \frac{2}{L}\left(x - \frac{1}{2}L\right)\right]\sin\left(\frac{n\pi x}{L}\right)dx\right\}dx$$

$$= \frac{32}{\pi^2 n^2}\cos\left(\frac{1}{4}n\pi\right)\sin^3\left(\frac{1}{4}n\pi\right)$$

$$= \frac{32}{\pi^2 n^2}\begin{cases}0 & n = 0, 4, \ldots\\ \frac{1}{4} & n = 1, 5, \ldots\\ 0 & n = 2, 6, \ldots\\ -\frac{1}{4} & n = 3, 7, \ldots\end{cases}$$

$$= \frac{8}{\pi^2 n^2}\begin{cases}(-1)^{(n-1)/2} & \text{for } n \text{ odd}\\ 0 & \text{for } n \text{ even.}\end{cases}$$

The Fourier series is therefore

$$f(x) = \frac{8}{\pi^2}\sum_{n=1,3,5,\ldots}^{\infty}\frac{(-1)^{(n-1)/2}}{n^2}\sin\left(\frac{n\pi x}{L}\right).$$

See also FOURIER SERIES

Fourier Sine Series

If $f(x)$ is an ODD FUNCTION, then $a_n = 0$ and the FOURIER SERIES collapses to

$$f(x) = \sum_{n=1}^{\infty} b_n \sin(nx), \qquad (1)$$

where

$$b_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\sin(nx)\,dx = \frac{2}{\pi}\int_0^{\pi} f(x)\sin(nx)\,dx \qquad (2)$$

for $n = 1, 2, 3, \ldots$. The last EQUALITY is true because

$$f(x)\sin(nx) = [-f(-x)][-\sin(-nx)]$$
$$= f(-x)\sin(-nx). \qquad (3)$$

Letting the range go to L,

$$b_n = \frac{2}{L}\int_0^L f(x)\sin\left(\frac{n\pi x}{L}\right)dx. \quad (4)$$

See also Fourier Cosine Series, Fourier Series, Fourier Sine Transform

Fourier Sine Transform

The Fourier sine transform is the imaginary part of the full complex Fourier transform,

$$\mathcal{F}_s[f(x)] = \Im[\mathcal{F}[f(x)]].$$

In *Mathematica* 4.0, the Fourier sine transform $F_s(k)$ of a function $f(x)$ is implemented as `FourierSinTransform[f, x, k]`, and different choices of a and b can be used by passing the optional `FourierParameters->{a, b}` option. In this work, $a = 0$ and $b = -2\pi$.

In version 4.1, the discrete Fourier sine transform of a list l of real numbers can be computed using `FourierSin[l]` in the *Mathematica* add-on package `LinearAlgebra`FourierTrig`` (which can be loaded with the command `<<LinearAlgebra``).

See also Fourier Cosine Transform, Fourier Transform

Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "FFT of Real Functions, Sine and Cosine Transforms." §12.3 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing, 2nd ed.* Cambridge, England: Cambridge University Press, pp. 504–15, 1992.

Fourier Transform

The Fourier transform is a generalization of the complex Fourier series in the limit as $L \to \infty$. Replace the discrete A_n with the continuous $F(k)dk$ while letting $n/L \to k$. Then change the sum to an integral, and the equations become

$$f(x) = \int_{-\infty}^{\infty} F(k)e^{2\pi ikx}dk \quad (1)$$

$$F(k) = \int_{-\infty}^{\infty} f(x)e^{-2\pi ikx}dx. \quad (2)$$

Here,

$$F(k) = \mathcal{F}[f(x)] = \int_{-\infty}^{\infty} f(x)e^{-2\pi ikx}dx \quad (3)$$

is called the *forward* $(-i)$ Fourier transform, and

$$f(x) = \mathcal{F}^{-1}[F(k)] = \int_{-\infty}^{\infty} F(k)e^{2\pi ikx}dk \quad (4)$$

is called the *inverse* $(+i)$ Fourier transform. The notation $f^{\wedge}(k)$ and $f^{\vee}(x)$ are sometimes used for the Fourier transform and inverse Fourier transform, respectively (Krantz 1999, p. 202).

Note that some authors (especially physicists) prefer to write the transform in terms of angular frequency $\omega \equiv 2\pi\nu$ instead of the oscillation frequency ν. However, this destroys the symmetry, resulting in the transform pair

$$H(\omega) = \mathcal{F}[h(t)] = \int_{-\infty}^{\infty} h(t)e^{-i\omega t}dt \quad (5)$$

$$h(t) = \mathcal{F}^{-1}[H(\omega)] = \frac{1}{2\pi}\int_{-\infty}^{\infty} H(\omega)e^{i\omega t}d\omega. \quad (6)$$

To restore the symmetry of the transforms, the convention

$$g(y) = \mathcal{F}[f(t)] = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} f(t)e^{-iyt}dt \quad (7)$$

$$f(t) = \mathcal{F}^{-1}[g(y)] = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} g(y)e^{iyt}dy \quad (8)$$

is sometimes used (Mathews and Walker 1970, p. 102). In general, the Fourier transform pair may be defined using two arbitrary constants a and b as

$$F(\omega) = \sqrt{\frac{|b|}{(2\pi)^{1-a}}}\int_{-\infty}^{\infty} f(t)e^{ib\omega t}dt \quad (9)$$

$$f(t) = \sqrt{\frac{|b|}{(2\pi)^{1+a}}}\int_{-\infty}^{\infty} F(\omega)e^{-ib\omega t}dw. \quad (10)$$

In *Mathematica* 4.0, the Fourier transform $F(k)$ of a function $f(x)$ is implemented as `FourierTransform[f, x, k]`, and different choices of a and b can be used by passing the optional `FourierParameters->{a, b}` option. By default, *Mathematica* takes `FourierParameters` as $(0, 1)$. Unfortunately, a number of other conventions are in widespread use. For example, $(0, 1)$ is used in modern physics, $(1, -1)$ is used in pure mathematics and systems engineering, $(1, 1)$ is used in probability theory for the computation of the characteristic function, $(-1, 1)$ is used in classical physics, and $(0, -2\pi)$ is used in signal processing. In this work, following Bracewell (1999, pp. 6–), *it is always assumed that* $a = 0$ and $b = -2\pi$ unless otherwise stated. This choice often results in greatly simplified transforms of common functions such as 1, $\cos(2\pi k_0 x)$, etc.

Since any function can be split up into even and odd portions $E(x)$ and $O(x)$,

$$f(x) = \tfrac{1}{2}[f(x) + f(-x)] + \tfrac{1}{2}[f(x) - f(-x)] = E(x) + O(x), \quad (11)$$

a Fourier transform can always be expressed in terms of the Fourier cosine transform and Fourier sine transform as

$$\mathcal{F}[f(x)] = \int_{-\infty}^{\infty} E(x)\cos(2\pi kx)dx - i\int_{-\infty}^{\infty} O(x)\sin(2\pi kx)dx. \quad (12)$$

A function $f(x)$ has a forward and inverse Fourier transform such that

$$f(x) = \begin{cases} \int_{-\infty}^{\infty} e^{2\pi ikx}\left[\int_{-\infty}^{\infty} f(x)e^{-2\pi ikx}dx\right]dk & \text{for } f(x) \text{ continuous at } x \\ \frac{1}{2}[f(x_+)+f(x_-)] & \text{for } f(x) \text{ discontinous at } x, \end{cases} \quad (13)$$

provided that

1. $\int_{-\infty}^{\infty}|f(x)|dx$ exists.
2. There are a finite number of discontinuities.
3. The function has bounded variation. A SUFFICIENT weaker condition is fulfillment of the LIPSCHITZ CONDITION

(Ramirez 1985, p. 29). The smoother a function (i.e., the larger the number of continuous DERIVATIVES), the more compact its Fourier transform.

The Fourier transform is linear, since if $f(x)$ and $g(x)$ have Fourier transforms $F(k)$ and $G(k)$, then

$$\int [af(x)+bg(x)]e^{-2\pi ikx}dx$$

$$= a\int_{-\infty}^{\infty} f(x)e^{-2\pi ikx}dx + b\int_{-\infty}^{\infty} g(x)e^{-2\pi ikx}dx$$

$$aF(k)+bG(k). \quad (14)$$

Therefore,

$$\mathcal{F}[af(x)+bg(x)] = a\mathcal{F}[f(x)] + b\mathcal{F}(g(x)] = aF(k)+bG(k). \quad (15)$$

The Fourier transform is also symmetric since $F(k) = \mathcal{F}[f(x)]$ implies $F(-k) = \mathcal{F}[f(-x)]$.

Let $f * g$ denote the CONVOLUTION, then the transforms of convolutions of functions have particularly nice transforms,

$$\mathcal{F}(f * g) = \mathcal{F}[f]\mathcal{F}[g] \quad (16)$$

$$\mathcal{F}[fg] = \mathcal{F}[f] * \mathcal{F}[g] \quad (17)$$

$$\mathcal{F}^{-1}[\mathcal{F}(f)\mathcal{F}(g)] = f * g \quad (18)$$

$$\mathcal{F}^{-1}[\mathcal{F}(f) * \mathcal{F}(g)] = fg. \quad (19)$$

The first of these is derived as follows:

$$\mathcal{F}[f * g] = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-2\pi ikx}f(x')g(x-x')dx'dx$$

$$= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\left[e^{-2\pi ikx'}f(x')dx'\right]\times\left[e^{-2\pi ik(x-x')}g(x-x')dx\right]$$

$$= \left[\int_{-\infty}^{\infty} e^{-2\pi ikx'}f(x')dx'\right]\left[\int_{-\infty}^{\infty} e^{-2\pi ikx''}g(x'')dx''\right]$$

$$= \mathcal{F}[f]\mathcal{F}[g], \quad (20)$$

where $x'' \equiv x - x'$.

There is also a somewhat surprising and extremely important relationship between the AUTOCORRELATION and the Fourier transform known as the WIENER-KHINTCHINE THEOREM. Let $\mathcal{F}[f(x)] = F(k)$, and $\bar{f}$ denote the COMPLEX CONJUGATE of f, then the Fourier transform of the ABSOLUTE SQUARE of $F(k)$ is given by

$$\mathcal{F}[|F(k)|^2] = \int_{-\infty}^{\infty} \bar{f}(\tau)f(\tau+x)d\tau. \quad (21)$$

The Fourier transform of a DERIVATIVE $f'(x)$ of a function $f(x)$ is simply related to the transform of the function $f(x)$ itself. Consider

$$\mathcal{F}[f'(x)] = \int_{-\infty}^{\infty} f'(x)e^{-2\pi ikx}dx. \quad (22)$$

Now use INTEGRATION BY PARTS

$$\int v\,du = [uv] - \int u\,dv \quad (23)$$

with

$$du = f'(x)dx \quad v = e^{-2\pi ikx} \quad (24)$$

$$u = f(x) \quad dv = -2\pi ike^{-2\pi ikx}dx, \quad (25)$$

then

$$\mathcal{F}[f'(x)] = \left[f(x)e^{-2\pi ikx}\right]_{-\infty}^{\infty} - \int_{-\infty}^{\infty} f(x)(-2\pi ike^{-2\pi ikx}dx). \quad (26)$$

The first term consists of an oscillating function times $f(x)$. But if the function is bounded so that

$$\lim_{x\to\pm\infty} f(x) = 0 \quad (27)$$

(as any physically significant signal must be), then the term vanishes, leaving

$$\mathcal{F}[f'(x)] = 2\pi ik\int_{-\infty}^{\infty} f(x)e^{-2\pi ikx}dx = 2\pi ikF[f(x)]. \quad (28)$$

This process can be iterated for the nth DERIVATIVE to yield

$$F\left[f^{(n)}(x)\right] = (2\pi ik)^n F[f(x)]. \quad (29)$$

The important MODULATION THEOREM of Fourier transforms allows $F[\cos(2\pi k_0 x)f(x)]$ to be expressed in terms of $\mathcal{F}[f(x)] = F(k)$ as follows,

$$\mathscr{F}[\cos(2\pi k_0 x)f(x)] \equiv \int_{-\infty}^{\infty} f(x)\cos(2\pi k_0 x)e^{-2\pi ikx}dx$$

$$= \tfrac{1}{2}\int_{-\infty}^{\infty} f(x)e^{2\pi ik_0 x}e^{-2\pi ikx}dx + \tfrac{1}{2}\int_{-\infty}^{\infty} f(x)e^{-2\pi ik_0 x}e^{-2\pi ikx}dx$$

$$= \tfrac{1}{2}\int_{-\infty}^{\infty} f(x)e^{-2\pi i(k-k_0)x}dx + \tfrac{1}{2}\int_{-\infty}^{\infty} f(x)e^{-2\pi i(k+k_0)x}dx$$

$$= \tfrac{1}{2}[F(k-k_0)+F(k+k_0)]. \tag{30}$$

Since the DERIVATIVE of the Fourier transform is given by

$$F'(k) \equiv \frac{d}{dx}\mathscr{F}[f(x)] = \int_{-\infty}^{\infty}(-2\pi ix)f(x)e^{-2\pi ikx}dx, \tag{31}$$

it follows that

$$F'(0) = -2\pi i\int_{-\infty}^{\infty} xf(x)dx. \tag{32}$$

Iterating gives the general FORMULA

$$\mu_n \equiv \int_{-\infty}^{\infty} x^n f(x)dx = \frac{F^{(n)}(0)}{(-2\pi i)^n}. \tag{33}$$

The VARIANCE of a FOURIER TRANSFORM is

$$\sigma_f^2 = \langle (xf - \langle xf\rangle)^2\rangle, \tag{34}$$

and it is true that

$$\sigma_{f+g} = \sigma_f + \sigma_g. \tag{35}$$

If $f(x)$ has the Fourier transform $F(k)$, then the Fourier transform has the shift property

$$\int_{-\infty}^{\infty} f(x-x_0)e^{-2\pi ikx}dx$$

$$= \int_{-\infty}^{\infty} f(x-x_0)e^{-2\pi i(x-x_0)k}e^{-2\pi i(kx_0)}d(x-x_0)$$

$$= e^{-2\pi ikx_0}F(k), \tag{36}$$

so $f(x-x_0)$ has the Fourier transform

$$F[f(x-x_0)] = e^{-2\pi ikx_0}F(k). \tag{37}$$

If $f(x)$ has a Fourier transform $F(k)$, then the Fourier transform obeys a similarity theorem.

$$\int_{-\infty}^{\infty} f(ax)e^{-2\pi ikx}dx = \frac{1}{|a|}\int_{-\infty}^{\infty} f(ax)e^{-2\pi i(ax)(k/a)}d(ax)$$

$$= \frac{1}{|a|}F\left(\frac{k}{a}\right), \tag{38}$$

so $f(ax)$ has the Fourier transform $|a|^{-1}F(k/a)$.

The "equivalent width" of a Fourier transform is

$$w_e \equiv \frac{\int_{-\infty}^{\infty} f(x)dx}{f(0)} = \frac{F(0)}{\int_{-\infty}^{\infty} F(k)dk}. \tag{39}$$

The "autocorrelation width" is

$$w_a \equiv \frac{\int_{-\infty}^{\infty} f * \bar{f}dx}{[f * \bar{f}]_0} = \frac{\int_{-\infty}^{\infty} fdx\int_{-\infty}^{\infty}\bar{f}dx}{\int_{-\infty}^{\infty} f\bar{f}dx}, \tag{40}$$

where $f * g$ denotes the CROSS-CORRELATION of f and g and $\bar{f}$ is the COMPLEX CONJUGATE.

Any operation on $f(x)$ which leaves its AREA unchanged leaves $F(0)$ unchanged, since

$$\int_{-\infty}^{\infty} f(x)dx = F[f(0)] = f(0). \tag{41}$$

In 2-D, the Fourier transform becomes

$$F(x,y) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(k_x,k_y)e^{-2\pi i(k_x x+k_y y)}dk_x dk_y \tag{42}$$

$$F(k_x,k_y) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,y)e^{2\pi i(k_x x+k_y y)}dxdy. \tag{43}$$

Similarly, the n-D Fourier transform can be defined for $\mathbf{k}$, $\mathbf{x}\in\mathbb{R}^n$ by

$$F(\mathbf{x}) = \underbrace{\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}}_{n} f(\mathbf{k})e^{-2\pi i\mathbf{k}\cdot\mathbf{x}}d^n\mathbf{k} \tag{44}$$

$$f(\mathbf{k}) = \underbrace{\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}}_{n} F(\mathbf{x})e^{-2\pi i\mathbf{k}\cdot\mathbf{x}}d^n\mathbf{x}. \tag{45}$$

Fourier Transform—1

The FOURIER TRANSFORM of the CONSTANT FUNCTION $f(x)=1$ is given by

$$\mathcal{F}[1]=\int_{-\infty}^{\infty} e^{-2\pi ikx}\,dx=\delta(k),$$

according to the definition of the DELTA FUNCTION.

See also DELTA FUNCTION, FOURIER TRANSFORM

Fourier Transform—Cosine

$$\mathcal{F}[\cos(2\pi k_0 x)]=\int_{-\infty}^{\infty} e^{2\pi ikx}\left(\frac{e^{2\pi ik_0x}+e^{-2\pi ik_0x}}{2}\right)dx$$

$$=\tfrac{1}{2}\int_{-\infty}^{\infty}\left[e^{-2\pi i(k-k_0)x}+e^{-2\pi i(k+k_0)x}\right]dx$$

$$=\tfrac{1}{2}[\delta(k-k_0)+\delta(k+k_0)],$$

where $\delta(x)$ is the DELTA FUNCTION.

See also COSINE, FOURIER TRANSFORM, FOURIER TRANSFORM–SINE

Fourier Transform—Delta Function

The FOURIER TRANSFORM of the DELTA FUNCTION is given by

$$\mathcal{F}[\delta(x-x_0)]=\int_{-\infty}^{\infty}\delta(x-x_0)e^{-2\pi ikx}\,dx=e^{-2\pi ikx_0}.$$

See also DELTA FUNCTION, FOURIER TRANSFORM

Fourier Transform—Exponential Function

The FOURIER TRANSFORM of $e^{-k_0|x|}$ is given by

$$\mathcal{F}\left[e^{-k_0|x|}\right]=\int_{-\infty}^{\infty} e^{-k_0|x|}e^{-2\pi ikx}\,dx$$

$$=\int_{-\infty}^{0} e^{-2\pi ikx}e^{2\pi xk_0}\,dx+\int_{0}^{\infty} e^{-2\pi ikx}e^{-2\pi k_0x}\,dx$$

$$=\int_{-\infty}^{0}[\cos(2\pi kx)-i\,\sin(2kx)]e^{2\pi k_0x}\,dx.$$

$$+\int_{0}^{\infty}[\cos(2\pi kx)-i\,\sin(2\pi kx)]e^{-2\pi k_0x}\,dx. \qquad (1)$$

Now let $u\equiv -x$ so $du=-dx$, then

$$\mathcal{F}\left[e^{-k_0|x|}\right]=\int_{0}^{\infty}[\cos(2\pi ku)+i\,\sin(2\pi ku)]e^{-2\pi k_0u}\,du$$

$$+\int_{0}^{\infty}[\cos(2\pi ku)-i\,\sin(2\pi ku)]e^{-2\pi k_0u}\,du$$

$$=2\int_{0}^{\infty}\cos(2\pi ku)e^{-2\pi kou}\,du, \qquad (2)$$

which, from the DAMPED EXPONENTIAL COSINE INTEGRAL, gives

$$\mathcal{F}\left[e^{-2\pi k_0|x|}\right] = \frac{1}{\pi}\frac{k_0}{k^2 + k_0^2}, \qquad (3)$$

which is a LORENTZIAN FUNCTION.

See also DAMPED EXPONENTIAL COSINE INTEGRAL, EXPONENTIAL FUNCTION, FOURIER TRANSFORM, LORENTZIAN FUNCTION

Fourier Transform—Gaussian

The FOURIER TRANSFORM of a GAUSSIAN FUNCTION $f(x) \equiv e^{-ax^2}$ is given by

$$F(k) = \int_{-\infty}^{\infty} e^{-ax^2} e^{-2\pi ikx} dx$$

$$= \int_{-\infty}^{\infty} e^{-ax^2} [\cos(2\pi kx) - i \sin(2\pi ix)] dx$$

$$= \int_{-\infty}^{\infty} e^{-ax^2} \cos(2\pi kx) dx - i\int_{-\infty}^{\infty} e^{-ax^2} \sin(2\pi kx) dx.$$

The second integrand is ODD, so integration over a symmetrical range gives 0. The value of the first integral is given by Abramowitz and Stegun (1972, p. 302, equation 7.4.6), so

$$F(k) = \sqrt{\frac{\pi}{a}} e^{-\pi^2 k^2/a},$$

and a GAUSSIAN transforms to a GAUSSIAN.

See also GAUSSIAN FUNCTION, FOURIER TRANSFORM

Fourier Transform—Heaviside Step Function

The FOURIER TRANSFORM of the HEAVISIDE STEP FUNCTION $H(x)$ is given by

$$\mathcal{F}[H(x)] = \int_{-\infty}^{\infty} e^{-2\pi ikx} H(x) dx = \frac{1}{2}\left[\delta(k) - \frac{i}{\pi k}\right],$$

where $\delta(k)$ is the DELTA FUNCTION.

See also FOURIER TRANSFORM, HEAVISIDE STEP FUNCTION

Fourier Transform—Inverse Function

The FOURIER TRANSFORM of the GENERALIZED FUNCTION $1/x$ is given by

$$\mathcal{F}\left(-PV\frac{1}{\pi x}\right) = -\frac{1}{\pi} PV\int_{-\infty}^{\infty} \frac{e^{-2\pi ikx}}{x} dx \qquad (1)$$

$$= PV\int_{-\infty}^{\infty} \frac{\cos(2\pi kx) - i\sin(2\pi kx)}{x} dx \qquad (2)$$

$$= \begin{cases} -\dfrac{2i}{\pi}\displaystyle\int_0^{\infty} \frac{\sin(2\pi kx)}{x} dx & \text{for } k < 0 \\ \dfrac{2i}{\pi}\displaystyle\int_0^{\infty} \frac{\sin(2\pi kx)}{x} dx & \text{for } k > 0 \end{cases} \qquad (3)$$

$$= \begin{cases} -i & \text{for } k < 0 \\ i & \text{for } k > 0, \end{cases} \qquad (4)$$

where PV denotes the CAUCHY PRINCIPAL VALUE. Equation (4) can also be written as the single equation

$$\mathcal{F}\left(-PV\frac{i}{\pi x}\right) = i[1 - 2H(-k)], \qquad (5)$$

where $H(x)$ is the HEAVISIDE STEP FUNCTION. The integrals follow from the identity

$$\int_0^{\infty} \frac{\sin(2\pi kx)}{x} dx = \int_0^{\infty} \frac{\sin(2\pi kx)}{2\pi kx} d(2\pi kx)$$

$$= \int_0^{\infty} \operatorname{sinc} z\, dz = \frac{1}{2}\pi. \qquad (6)$$

See also FOURIER TRANSFORM

Fourier Transform—Lorentzian Function

$$\mathcal{F}\left[\frac{1}{\pi}\frac{\frac{1}{2}\Gamma}{(x - x_0)^2 + \left(\frac{1}{2}\Gamma\right)^2}\right] = e^{-2\pi ikx_0 - \Gamma\pi|k|}.$$

This transform arises in the computation of the CHARACTERISTIC FUNCTION of the CAUCHY DISTRIBUTION.

See also FOURIER TRANSFORM, LORENTZIAN FUNCTION

Fourier Transform—Ramp Function

Let $R(x)$ be the RAMP FUNCTION, then the FOURIER TRANSFORM of $R(x)$ is given by

$$\mathcal{F}[R(x)] = \int_{-\infty}^{\infty} e^{-2\pi ikx} R(x) dx = \pi i\delta'(2\pi k) - \frac{1}{4\pi^2 k^2},$$

where $\delta'(x)$ is the DERIVATIVE of the DELTA FUNCTION.

See also RAMP FUNCTION

Fourier Transform—Rectangle Function

Let $\Pi(x)$ be the RECTANGLE FUNCTION, then the FOURIER TRANSFORM is

$$\mathscr{F}[\Pi(x)] = \text{sinc}(\pi k),$$

where $\text{sinc}(x)$ is the SINC FUNCTION.

See also FOURIER TRANSFORM, RECTANGLE FUNCTION, SINC FUNCTION

Fourier Transform—Sine

$$\mathscr{F}[\sin(2\pi k_0 x)] = \int_{-\infty}^{\infty} e^{-2\pi ikx}\left(\frac{e^{2\pi ik_0x} - e^{-2\pi ik_0x}}{2i}\right)dx$$

$$= \tfrac{1}{2}i\int_{-\infty}^{\infty}\left[-e^{-2\pi i(k-k_0)x} + e^{-2\pi i(k+k_0)x}\right]dt$$

$$= \tfrac{1}{2}i[\delta(k+k_0) - \delta(k-k_0)],$$

where $\delta(x)$ is the DELTA FUNCTION.

HANKEL TRANSFORM

Fourier-Budan Theorem

For any real α and β such that $\beta > \alpha$, let $p(\alpha) \neq 0$ and $p(\beta) \neq 0$ be real polynomials of degree n, and $v(x)$ denote the number of sign changes in the sequence $\{p(x), p'(x), ..., p^{(n)}(x)\}$. Then the number of zeros in the interval $[\alpha, \beta]$ (each zero counted with proper multiplicity) equals $v(\alpha) - v(\beta)$ minus an even nonnegative integer.

Fourier-Mellin Integral

The inverse of the LAPLACE TRANSFORM

$$\text{F(t)} = \mathscr{L}^{-1}[f(s)] = \frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty} e^{st}f(s)ds$$

$$f(s) = \mathscr{L}[\text{F(t)}] = \int_0^{\infty}\text{F(t)e}^{-\text{st}}dt.$$

See also BROMWICH INTEGRAL, LAPLACE TRANSFORM

Fourier-Stieltjes Transform

Let $f(x)$ be a positive definite, measurable function on the INTERVAL $(-\infty, \infty)$. Then there exists a monotone increasing, real-valued bounded function $\alpha(t)$ such that

$$f(x) = \int_{-\infty}^{\infty} e^{itx}d\alpha(t)$$

for "ALMOST ALL" x. If $\alpha(t)$ is nondecreasing and bounded and $f(x)$ is defined as above, then $f(x)$ is called the Fourier-Stieltjes transform of $\alpha(t)$, and is both continuous and positive definite.

Four-Knot

FIGURE-OF-EIGHT KNOT

Four-Square Theorem

LAGRANGE'S FOUR-SQUARE THEOREM

Four-Vector

A four-element vector

$$a^\mu = \begin{bmatrix} a^0 \\ a^1 \\ a^2 \\ a^3 \end{bmatrix}, \quad (1)$$

which transforms under a LORENTZ TRANSFORMATION like the POSITION FOUR-VECTOR. This means it obeys

$$a'^\mu = \Lambda^\mu_\nu a^\nu \quad (2)$$

$$a_\mu \cdot b_\mu \equiv a_\mu b^\mu \quad (3)$$

$$a_\mu \cdot b^\mu = a'_\mu b'_\mu \quad (4)$$

where Λ^μ_μ is the LORENTZ TENSOR. Multiplication of two four-vectors with the METRIC $g_{\mu\nu}$ gives products OF THE FORM

$$g_{\mu\nu}x^\mu x^\nu = (x^0)^2 - (x^1)^2 - (x^2)^2 - (x^3)^2. \quad (5)$$

In the case of the POSITION FOUR-VECTOR, $x^0 = ct$ (where c is the speed of light) and this product is an invariant known as the spacetime interval.

Fox's H-Function

A very general function defined by

$$H(z)=H_{p,q}^{m,n}\left[z\left|\begin{matrix}(a_1,\alpha_1),\ldots,(a_p,\alpha_p)\\(b_1,\beta_1),\ldots,(b_p,\beta_p)\end{matrix}\right.\right]$$

$$=\frac{1}{2\pi i}\int_C\frac{\Pi_{j=1}^{m}\Gamma(b_j-\beta_i s)\Pi_{j=1}^{n}\Gamma(1-a_j+a_j s)}{\Pi_{j=m+1}^{q}\Gamma(1-b_j+\beta_j s)\Pi_{j=n+1}^{qp}\Gamma(a_j-a_j s)}$$

$$\times z^s ds,$$

where $0\leq m\leq q$, $0\leq n\leq p$, $\alpha_j,\beta_j>0$, and a_j,b_j are complex numbers such that the pole of $\Gamma(b_j-\beta_j s)$ for $j=1$, 2, ..., m coincides with any pole of $\Gamma(1-a_j+\alpha_j s)$ for $j=1$, 2, ..., n. In addition C, is a contour in the complex s-plane from $\omega-i\infty$ to $\omega+i\infty$ such that $(b_j+k)/\beta_j$ and $(a_j-1-k)/\alpha_j$ lie to the right and left of C, respectively.

A. Kilbas has derived a complete description for the asymptotic expansion of the H-function.

F-Polynomial

Kauffman Polynomial F

Frac

Fractional Part

Fractal

An object or quantity which displays self-similarity, in a somewhat technical sense, on all scales. The object need not exhibit *exactly* the same structure at all scales, but the same "type" of structures must appear on all scales. A plot of the quantity on a log-log graph versus scale then gives a straight line, whose slope is said to be the fractal dimension. The prototypical example for a fractal is the length of a coastline measured with different length rulers. The shorter the ruler, the longer the length measured, a paradox known as the coastline paradox.

Illustrated above are the fractals known as the Gosper island, Koch snowflake, box fractal, Sierpinski sieve, Barnsley's fern, and Mandelbrot set.

Fractal Dimension

The term "fractal dimension" is sometimes used to refer to what is more commonly called the CAPACITY DIMENSION (which is, roughly speaking, the exponent D in the expression $n(\epsilon) = \epsilon^{-D}$, where $n(\epsilon)$ is the minimum number of OPEN SETS of diameter ϵ needed to cover the set). However, it can more generally refer to any of the dimensions commonly used to characterize fractals (e.g., CAPACITY DIMENSION, CORRELATION DIMENSION, INFORMATION DIMENSION, LYAPUNOV DIMENSION, MINKOWSKI-BOULIGAND DIMENSION).

See also BOX-COUNTING DIMENSION, CAPACITY DIMENSION, CORRELATION DIMENSION, FRACTAL DIMENSION, HAUSDORFF DIMENSION, INFORMATION DIMENSION, LYAPUNOV DIMENSION, MINKOWSKI-BOULIGAND DIMENSION, POINTWISE DIMENSION, Q-DIMENSION

Fractal Land

CAROTID-KUNDALINI FRACTAL

Fractal Process

A 1-D MAP whose increments are distributed according to a NORMAL DISTRIBUTION. Let $y(t-\Delta t)$ and $y(t+\Delta t)$ be values, then their correlation is given by the BROWN FUNCTION

$$r = 2^{2H-1} - 1.$$

When $H = 1/2$, $r = 0$ and the fractal process corresponds to 1-D Brownian motion. If $H > 1/2$, then $r > 0$ and the process is called a PERSISTENT PROCESS.

If $H < 1/2$, then $r < 0$ and the process is called an ANTIPERSISTENT PROCESS.

See also ANTIPERSISTENT PROCESS, PERSISTENT PROCESS

References

von Seggern, D. *CRC Standard Curves and Surfaces.* Boca Raton, FL: CRC Press, 1993.

Fractal Sequence

Given an INFINITIVE SEQUENCE $\{x_n\}$ with associated array $a(i,j)$, then $\{x_n\}$ is said to be a fractal sequence

1. If $i+1=x_n$, then there exists $m<n$ such that $i=x_m$,
2. If $h<i$, then, for every j, there is exactly one k such that $a(i,j)<a(h,k)<a(i,j+1)$.

(As i and j range through N, the array $A=a(i,j)$, called the associative array of x, ranges through all of N.) An example of a fractal sequence is 1, 1, 1, 1, 2, 1, 2, 1, 3, 2, 1, 3, 2, 1, 3, ...

If $\{x_n\}$ is a fractal sequence, then the associated array is an INTERSPERSION. If x is a fractal sequence, then the UPPER-TRIMMED SUBSEQUENCE is given by $\lambda(x)=x$, and the LOWER-TRIMMED SUBSEQUENCE $V(x)$ is another fractal sequence. The SIGNATURE of an IRRATIONAL NUMBER is a fractal sequence.

Fractal Valley

CAROTID-KUNDALINI FUNCTION

Fractile

QUANTILE

Fraction

A RATIONAL NUMBER expressed in the form a/b (in-line notation) or $\frac{a}{b}$ (traditional "display" notation), where a is called the NUMERATOR and b is called the DENOMINATOR. When written in-line, the slash "/" between NUMERATOR and DENOMINATOR is called a SOLIDUS.

A PROPER FRACTION is a fraction such that $a/b<1$, and a LOWEST TERMS FRACTION is a fraction with common terms canceled out of the NUMERATOR and DENOMINATOR.

The Egyptians expressed their fractions as sums (and differences) of UNIT FRACTIONS. Conway and Guy (1999) give a table of Roman NOTATION for fractions, in which multiples of 1/12 (the UNCIA) were given separate names.

See also ADJACENT FRACTION, ANOMALOUS CANCELLATION, COMMON FRACTION, COMPLEX FRACTION, CONTINUED FRACTION, DENOMINATOR, EGYPTIAN FRACTION, FAREY SEQUENCE, GOLDEN RULE, HALF, LOWEST TERMS FRACTION, MATRIX FRACTION, MEDIANT, MIXED FRACTION, NUMERATOR, PANDIGITAL FRACTION, PROPER FRACTION, PYTHAGOREAN FRACTION, QUARTER, RATIONAL NUMBER, SOLIDUS, UNIT FRACTION

Fractional Calculus

The study of an extension of derivatives and integrals to noninteger orders. Fractional calculus is based on the definition of the FRACTIONAL INTEGRAL as

$$D^{-\nu}f(t)=\frac{1}{\Gamma(\nu)}\int_0^t (t-\xi)^{\nu-1}f(\xi)d\xi,$$

where $\Gamma(\nu)$ is the GAMMA FUNCTION. From this equation, FRACTIONAL DERIVATIVES can also be defined.

See also DERIVATIVE, FRACTIONAL DERIVATIVE, FRACTIONAL DIFFERENTIAL EQUATION, FRACTIONAL INTEGRAL, INTEGRAL, MULTIPLE INTEGRAL

Spanier, J. and Oldham, K. B. *The Fractional Calculus: Integrations and Differentiations of Arbitrary Order.* New York: Academic Press, 1974.

Fractional Derivative

The fractional derivative of $f(t)$ of order $\mu>0$ (if it exists) can be defined in terms of the FRACTIONAL INTEGRAL $D^{-\nu}f(t)$ as

$$D^{\mu}f(t)=D^{m}\left[D^{-(m-\mu)}f(t)\right], \quad (1)$$

where m is an integer $\geq \lceil \mu \rceil$, where $\lceil x \rceil$ is the CEILING FUNCTION. The SEMIDERIVATIVE corresponds to $\mu=1/2$.

The fractional derivative of the function t^λ is given by

$$D^\mu t^\lambda = D^m\left[D^{-(m-\mu)}t^\lambda\right]$$

$$= D^n\left[\frac{\Gamma(\lambda+1)}{\Gamma(\lambda+m-\mu+1)}t^{\lambda+m-\mu}\right]$$

$$= \frac{\Gamma(\lambda+1)(\lambda-\mu+m)(\lambda-\mu+m-1)\cdots(\lambda-\mu+1)}{\Gamma(1+m+\lambda-\mu)}t^{\lambda-\mu}$$

$$= \frac{\Gamma(\lambda+1)(1+\lambda-\mu)_m}{\Gamma(1+m+\lambda-\mu)}t^{\lambda-\mu}$$

$$= \frac{\Gamma(\lambda+1)}{\Gamma(\lambda-\mu+1)}t^{\lambda-\mu} \quad (2)$$

for $\lambda > -1, \mu > 0$. The fractional derivative of the CONSTANT FUNCTION $f(t) = c$ is then given by

$$D^\mu c = c\lim_{\lambda\to 0}\frac{\Gamma(\lambda+1)}{\Gamma(\lambda-\mu+1)}t^{\lambda-\mu} = \frac{ct^{-\mu}}{\Gamma(1-\mu)}. \quad (3)$$

The fractional derivate of the Et-FUNCTION is given by

$$D^\rho E_t(\nu, a) = E_t(\nu-\rho, a) \quad (4)$$

for $\nu > 0, \rho \neq 0$.

It is always true that, for $\mu, \nu > 0$,

$$D^{-\mu}D^{-\nu}f(t) = D^{-(\mu+\nu)} \quad (5)$$

but *not* always true that

$$D^\mu D^\nu = D^{\mu+\nu} \quad (6)$$

A FRACTIONAL INTEGRAL can also be similarly defined. The study of fractional derivatives and integrals is called FRACTIONAL CALCULUS.

Fractional Differential Equation

The solution to the differential equation

$$\left[D^{2v} + aD^v + bD^0\right]y(t) = 0$$

is

$$y(t) = \begin{cases} e_\alpha(t) - e_\beta(t) \\ \quad \text{for } \alpha \neq \beta \\ te^{\alpha t}, \sum_{k=-(q-1)}^{q-1}\alpha^k(q-|k|)D^{1-(k+1)v}(te^{\alpha^q t}) \\ \quad \text{for } \alpha = \beta \neq 0 \\ \dfrac{t^{2v-1}}{\Gamma(2v)} \\ \quad \text{for } \alpha = \beta = 0, \end{cases}$$

where

$$q = \frac{1}{v}$$

$$e_\beta(t) = \sum_{k=0}^{q-1}\beta^{q-k-1}E_t(-kv, \beta^q),$$

$E_t(a, x)$ is the Et-FUNCTION, and $\Gamma(n)$ is the GAMMA FUNCTION.

Fractional Fourier Transform

The fractional Fourier transform is generally understood to correspond to a rotation in time-frequency phase space, where the usual FOURIER TRANSFORM corresponds to a rotation of 90° ($\pi/2$ radians). A fractional Fourier transform can be used to detect frequencies which are not INTEGER multiples of the lowest DISCRETE FOURIER TRANSFORM frequency.

See also DISCRETE FOURIER TRANSFORM, FOURIER TRANSFORM

Fractional Integral

Denote the nth DERIVATIVE D^n and the n-fold INTEGRAL D^{-n}. Then

$$D^{-1}f(t) = \int_0^t f(\xi)\,d\xi. \quad (1)$$

Now, if the equation

$$D^{-n}f(t) = \frac{1}{(n-1)!}\int_0^t (t-\xi)^{n-1}f(\xi)\,d\xi \quad (2)$$

for the MULTIPLE INTEGRAL is true for n, then

$$D^{-(n+1)}f(t) = D^{1}\left[\frac{1}{(n-1)!}\int_0^t (t-\xi)^{n-1}f(\xi)\,d\xi\right]$$

$$= \int_0^t \left[\frac{1}{(n-1)!}\int_0^x (x-\xi)^{n-1}f(\xi)d\xi\right] dx. \tag{3}$$

Interchanging the order of integration gives

$$D^{-(n+1)}f(t) = \frac{1}{n!}\int_0^t (t-\xi)^n f(\xi)\,d\xi. \tag{4}$$

But (2) is true for $n = 1$, so it is also true for all n by INDUCTION. The fractional integral of $f(t)$ of order $\nu > 0$ can then be defined by

$$D^{-\nu}f(t) = \frac{1}{\Gamma(\nu)}\int_0^t (t-\xi)^{\nu-1}f(\xi)d\xi, \tag{5}$$

where $\Gamma(\nu)$ is the GAMMA FUNCTION.

The fractional integral of order 1/2 is called a SEMI-INTEGRAL.

The fractional integral can only be given in terms of elementary functions for a small number of functions. For example,

$$D^{-\nu}t^{\lambda} = \frac{\Gamma(\lambda+1)}{\Gamma(\lambda+\nu+1)}t^{\lambda+\nu} \quad \text{for } \lambda > -1, \nu > 0 \tag{6}$$

$$D^{-\nu}e^{at} = \frac{1}{\Gamma(\nu)}e^{at}\int_0^t x^{\nu-1}e^{-ax}dx$$

$$= \frac{a^{-\nu}e^{at}\gamma(\nu, at)}{\Gamma(\nu)} = \equiv E_t(\nu, a), \tag{7}$$

where $\gamma(a, x)$ is a lower incomplete GAMMA FUNCTION and $E_t(\nu, a)$ is the *Et*-FUNCTION. From (6), the fractional integral of the CONSTANT FUNCTION $f(t) = c$ is given by

$$D^{-\nu}c = c\lim_{\lambda\to 0}\frac{\Gamma(\lambda+1)}{\Gamma(\lambda+\nu+1)}t^{\lambda+\nu} = \frac{t^{\mu}}{\Gamma(\nu+1)}. \tag{8}$$

A FRACTIONAL DERIVATIVE can also be similarly defined. The study of fractional derivatives and integrals is called FRACTIONAL CALCULUS.

See also FRACTIONAL CALCULUS, SEMI-INTEGRAL

Fractional Part

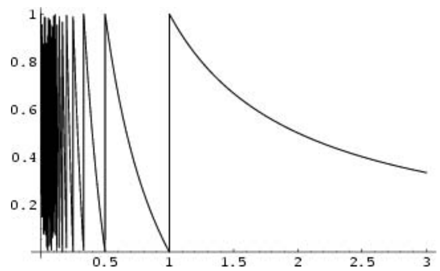
The function frac x giving the fractional (noninteger) part of a REAL NUMBER x. The symbol $\{x\}$ is sometimes used instead of frac x (Graham *et al.* 1994, p. 70), but this notation is not used in this work due to possible confusion with the SET containing the element x.

Unfortunately, there is no universal agreement on the meaning of frac x for $x < 0$ and there are two common definitions. Let $\lfloor x \rfloor$ be the FLOOR FUNCTION, then the *Mathematica* command `FractionalPart[x]` is defined as

$$\text{frac } x \equiv \begin{cases} x - \lfloor x \rfloor & x \geq 0 \\ x - \lfloor x \rfloor - 1 & x < 0 \end{cases} \tag{1}$$

(left figure). This definition has the benefit that frac x + int $x = x$, where int x is the INTEGER PART of x. Although Spanier and Oldham (1987) use the same definition as *Mathematica*, they mention the formula only very briefly and then say it will not be used further. Graham *et al.* (1994, p. 70), and perhaps most other mathematicians, use the different definition

$$\text{frac } x = x - \lfloor x \rfloor, \tag{2}$$



(right figure).

Since usage concerning fractional part/value and integer part/value can be confusing, the following table gives a summary of names and notations used (D. W. Cantrell). Here, S&O indicates Spanier and Oldham (1987).

notation	name	S&O	Graham *et al.*	*Mathematica*
$\lfloor x \rfloor$	integer-value	Int(x)	floor or integer part	`Floor[x]`

$\operatorname{sgn}(x)\lfloor\lvert x\rvert\rfloor$	integer-part	$\operatorname{Ip}(x)$	no name	`IntegerPart[x]`
$x-\lfloor x\rfloor$	fractional-value	$\operatorname{frac}(x)$	fractional part or $\{x\}$	no name
$\operatorname{sgn}(x)(\lvert x\rvert-\lfloor\lvert x\rvert\rfloor)$	fractional-part	$\operatorname{F_P}(x)$	no name	`FractionalPart[x]`

The (possibly scaled) periodic waveform corresponding to the latter definition is known as the SAWTOOTH WAVE.

The fractional part of $1/x$ has the interesting analytic integrals

$$\int_{1/2}^{1}\operatorname{frac}\left(\frac{1}{x}\right)dx=\int_{1/2}^{1}\left(\frac{1}{x}-1\right)dx=\ln 2-\tfrac{1}{2} \tag{3}$$

$$\int_{1/3}^{1/2}\operatorname{frac}\left(\frac{1}{x}\right)dx=\int_{1/3}^{1/2}\left(\frac{1}{x}-2\right)dx=\ln 3-\ln 2-\tfrac{1}{3} \tag{4}$$

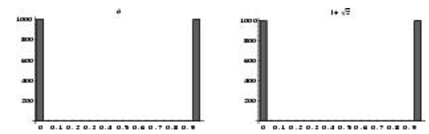
$$\int_{1/4}^{1/3}\operatorname{frac}\left(\frac{1}{x}\right)dx=\int_{1/4}^{1/3}\left(\frac{1}{x}-3\right)dx$$

$$=\ln 4-\ln 3-\tfrac{1}{4}. \tag{5}$$

The integral

$$I=\int_{0}^{1}\operatorname{frac}\left(\frac{1}{x}\right)dx \tag{6}$$

is therefore a TELESCOPING SUM given by



$$I=\int_{0}^{1}\operatorname{frac}\left(\frac{1}{x}\right)dx=\lim_{n\to\infty}\left[\ln n-\sum_{k=2}^{n}\frac{1}{k}\right]$$

$$=1-\gamma+\lim_{n\to\infty}(\ln n-\Psi_0(1+n)), \tag{7}$$

where γ is the EULER-MASCHERONI CONSTANT and $\Psi_k(x)$ is the POLYGAMMA FUNCTION. The quantity on the right is 0, so

$$I=1-\gamma. \tag{8}$$

A consequence of WEYL'S CRITERION is that the sequence $\{\operatorname{frac}(nx)\}$ is dense and EQUIDISTRIBUTED in the interval $[0, 1]$ for irrational x, where $n = 1, 2, ...$ (finch).

Hardy and Littlewood (1914) proved that the sequence $\{\operatorname{frac}(x^n)\}$ is EQUIDISTRIBUTED for *almost all* real numbers $x>1$ (i.e., the exceptional set has LEBESGUE MEASURE ZERO). Exceptional numbers include the positive integers, $1+\sqrt{2}$ (Finch), and the GOLDEN RATIO ϕ. The plots above illustrate the distribution of $\operatorname{frac}(x^n)$ for $x=e$, ϕ, and $1+\sqrt{2}$. Candidate members of the *measure one* set are easy to find, but difficult to proven. However, Levin has explicitly constructed such an example (Drmota and Tichy 1997).

The properties of $\{\operatorname{frac}((3/2)^n)\}$, the simplest such sequence for a rational number $x>1$ have been extensively studied (Finch). For example, $\{\operatorname{frac}((3/2)^n)\}$ has infinitely many ACCUMULATION POINTS in both $[0, 1/2]$ and $[1/2, 1]$ (Pisot 1938, Vijayaraghavan 1941). Furthermore, Flatto *et al.* (1995) proved that any subinterval of $[0, 1]$ containing all but at most finitely many ACCUMULATION POINTS of $\operatorname{frac}((3/2)^n)$ must have length at least 1/3. Surprisingly, the sequence $\{\operatorname{frac}((3/2)^n)\}$ is also connected with the COLLATZ PROBLEM and with WARING'S PROBLEM.

In particular, WARING'S PROBLEM can be solved completely if the inequality

$$\operatorname{frac}\left[\left(\frac{3}{2}\right)^n\right]\leq 1-\left(\frac{3}{4}\right)^n \tag{9}$$

holds. No counterexample to this inequality is known, and it is even believed that can be extended to

$$\left(\frac{3}{4}\right)^n<\operatorname{frac}\left[\left(\frac{3}{2}\right)^n\right]<1-\left(\frac{3}{4}\right)^n \tag{10}$$

for $n>7$ (Finch; Bennett 1993, 1994). Furthermore, the constant 3/4 can be decreased to 0.5769 (Beukers 1981 and Dubitskas 1990). Unfortunately, these inequalities have not been proved.

Fractran

Fractran is an algorithm applied to a given list f_1, f_2, ..., f_k of FRACTIONS. Given a starting INTEGER N, the Fractran algorithm proceeds by repeatedly multiplying the integer at a given stage by the first element f_t given an integer PRODUCT. The algorithm terminates when there is no such f_t.

The list

$$\frac{17}{91}, \frac{78}{85}, \frac{19}{51}, \frac{23}{38}, \frac{29}{33}, \frac{77}{29}, \frac{95}{23}, \frac{77}{19}, \frac{1}{17}, \frac{11}{13}, \frac{13}{11}, \frac{15}{2}, \frac{1}{7}, \frac{55}{1}$$

with starting integer $N = 2$ generates a sequence 2, 15, 825, 725, 1925, 2275, 425, 390, 330, 290, 770, ... (Sloane's A007542). Conway (1987) showed that the only other powers of 2 which occur are those with PRIME exponent: 2^2, 2^3, 2^5, 2^7, ...

Frame

A closed curve associated with a knot which is displaced along the normal by a small amount. For K is parameterized by $x^\mu(s)$ for $0 \le s \le L$ along the length of the knot by parameter s, the frame K_f associated with K is

$$y^\mu = x^\mu(s) + \epsilon n^\mu(s),$$

where ϵ is a small parameter, $n^\mu(s)$ is a unit VECTOR FIELD normal to the curve at s.

Fréchet Bounds

Any bivariate distribution function with marginal distribution functions F and G satisfies

$$\max\{F(x)+G(y)-1,0\} \le H(x,y) \le \min\{F(x),G(y)\}.$$

Fréchet Derivative

A function f is Fréchet differentiable at a if

$$\lim_{x\to a}\frac{f(x)-f(a)}{x-a}$$

exists. This is equivalent to the statement that ϕ has a removable DISCONTINUITY at a, where

$$\phi(x) \equiv \frac{f(x)-f(a)}{x-a}.$$

Every function which is Fréchet differentiable is also Carathéodory differentiable.

See also CARATHÉODORY DERIVATIVE, DERIVATIVE

Fréchet Filter

COFINITE FILTER

Fréchet Space

A complete metrizable space, sometimes also with the restriction that the space be locally convex. A Fréchet space is a TOPOLOGICAL VECTOR SPACE which is COMPLETE. Its topology is also defined by a COUNTABLE family of SEMINORMS.

For example, the space of SMOOTH FUNCTIONS on $[0, 1]$ is a Fréchet space. Its topology is the C-INFINITY TOPOLOGY, which is given by the countable family of SEMINORMS,

$$\|f\|_\alpha = \sup|D^\alpha f|.$$

Because $f_n \to f$ in this topology implies that f is smooth, i.e.,

$$D^\alpha f_n \to D^\alpha f,$$

any CAUCHY SEQUENCE has a limit in the space of SMOOTH FUNCTIONS, i.e., it is COMPLETE.

Fredholm's Theorem

This entry contributed by VIKTOR BENGTSSON

Fredholm's theorem states that, if A is an $m \times n$ matrix, then the ORTHOGONAL COMPLEMENT of the ROW SPACE of A is the NULLSPACE of A, and the ORTHOGONAL COMPLEMENT of the COLUMN SPACE of A is the NULLSPACE of $\mathsf{A}^\perp$,

$$(\text{Row } \mathsf{A})^\perp = \text{Null } \mathsf{A}$$

$$(\text{Col } \mathsf{A})^\perp = \text{Null } \mathsf{A}^\perp.$$

See also Column Space, Nullspace, Orthogonal Decomposition, Row Space

Free

When referring to a planar object, "free" means that the object is regarded as capable of being picked up out of the plane and flipped over. As a result, mirror images are equivalent for free objects.

The word "free" is also used in technical senses to refer to a free group, free semigroup, free tree, free variable, etc.

In algebraic topology, a free abstract mathematical object is generated by n elements in a "free manner" ("freely"), i.e., such that the n elements satisfy no nontrivial relations among themselves. To make this more formal, an algebraic gadget X is freely generated by a subset G if, for any function $f: G \to Y$ where Y is any other algebraic gadget, there exists a unique homomorphism (which has different meanings depending on what kind of gadgets you're dealing with) $g: X \to Y$ such that g restricted to G is f.

If the algebraic gadgets are vector spaces, then G freely generates X iff G is a basis for X. If the algebraic gadgets are Abelian groups, then G freely generates X iff X is a direct sum of the integers, with G consisting of the standard basis.

See also Fixed, Free Group, Free Variable, Freely, Gadget, Mirror Image, Rank

Free Abelian Group

A free Abelian group is a group G with a subset which generates the group G with the only relation being $ab = ba$. That is, it has no torsion. All such groups are a direct product of the integers $\mathbb{Z}$, and have rank given by the number of copies of $\mathbb{Z}$. For example, $\mathbb{Z} \times \mathbb{Z} = \{(n, m)\}$ is a free Abelian group of rank 2. A minimal subset b_1, ..., b_n that generates a free Abelian group is called a basis, and gives G as

$$G = \mathbb{Z}b_1 + \cdots + \mathbb{Z}b_n.$$

A free Abelian group is an Abelian group, but is not a free group (except when it has rank one, i.e., $\mathbb{Z}$). Free Abelian groups are the free modules in the case when the ring is the ring of integers $\mathbb{Z}$.

See also Abelian Group, Free Group, Free Module, Group, Torsion (Group)

Free Action

A group action $G \times X \to X$ is called free when there are no fixed points. That is, for any point x there is at least one transformation which does not fix x. The group is said to act freely.

The basic example of a free group action is the action of a group on itself by left multiplication $L: G \times G \to G$. As long as the group has more than the identity element, there is no element h which satisfies $gh = h$ for all g. An example of a free action which is not transitive is the action of $\mathbb{S}^1$ on $\mathbb{S}^3 \subset \mathbb{C}^2$ by $e^{i\theta} \cdot (\mathbb{Z}_1, \mathbb{Z}_2) = (e^{i\theta}\mathbb{Z}_1, e^{i\theta}\mathbb{Z}_2)$, which defines the Hopf fibration.

See also Effective Action, Free Action, Group, Isotropy Group, Matrix Group, Orbit (Group), Quotient Space (Lie Group), Representation, Topological Group, Transitive Group Action

Free Group

The generators of a group G are defined to be the smallest subset of group elements such that all other elements of G can be obtained from them and their inverses. A group is a free group if no relation exists between its generators (other than the relationship between an element and its inverse required as one of the defining properties of a group). For example, the additive group of whole numbers is free with a single generator, 1.

See also Free Abelian Group, Free Semigroup

Free Semigroup

A semigroup with a noncommutative product in which no product can ever be expressed more simply in terms of other elements.

See also Free Group, Semigroup

Free Tree

A tree which is not rooted, i.e., a normal tree with no node singled out for special treatment (Skiena 1990, p. 107).

See also Rooted Tree, Tree

French Curve

French curves are plastic (or wooden) templates having an edge composed of several different curves. French curves are used in drafting (or were before computer-aided design) to draw smooth curves of almost any desired curvature in mechanical drawings. Several typical French curves are illustrated above.

While an undergraduate at MIT, Feynman (1997, p. 23) used a French curve to illustrate the fallacy of learning without understanding. When he pointed out to his colleagues in a mechanical drawing class the "amazing" fact that the TANGENT at each point on the curve was horizontal, none of his classmates realized that this was trivially true, since the DERIVATIVE (tangent) at an extremum (lowest or highest point) of *any* curve is zero (horizontal), as they had already learned in CALCULUS class.

French Metro Metric

The French metro metric is an example for disproving apparently intuitive but false properties of METRIC SPACES. The metric consists of a distance function on the plane such that for all $a, b \in \mathbb{R}^2$,

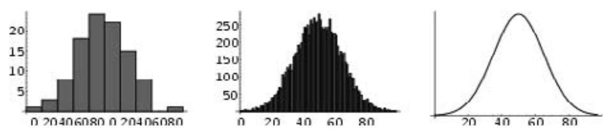
$$d(a,b) = \begin{cases} |a-b| & \text{if } a = cb \quad \text{for some} \quad c \in \mathbb{R} \\ |a|+|b| & \text{otherwise,} \end{cases}$$

where $|a|$ is the normal distance function on the plane. This metric has the property that for $r < |a|$, the OPEN BALL of radius r around a is an open line segment along vector a, while for $r > |a|$, the OPEN BALL is the union of a line segment and an OPEN DISK around the origin.

Frenet Formulas

Also known as the Serret-Frenet formulas, these vector differential equations relate inherent properties of a parametrized curve. In matrix form, they can be written

$$\begin{bmatrix} \dot{\mathbf{T}} \\ \dot{\mathbf{N}} \\ \dot{\mathbf{B}} \end{bmatrix} = \begin{bmatrix} 0 & \kappa & 0 \\ -\kappa & 0 & \tau \\ 0 & -\tau & 0 \end{bmatrix} \begin{bmatrix} \mathbf{T} \\ \mathbf{N} \\ \mathbf{B} \end{bmatrix},$$



where $\mathbf{T}$ is the unit TANGENT VECTOR, $\mathbf{N}$ is the unit NORMAL VECTOR, $\mathbf{B}$ is the unit BINORMAL VECTOR, τ is the TORSION, κ is the CURVATURE, and $\dot{\mathbf{x}}$ denotes $d\mathbf{x}/ds$.

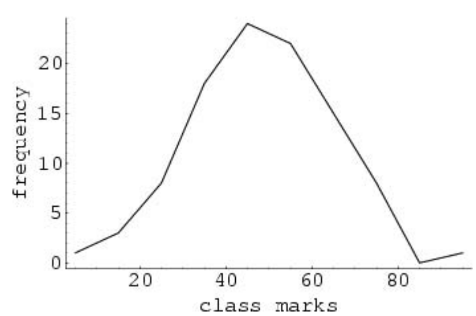
Kenney, J. F. and Keeping, E. S. "Frequency Curves." §2.5 in *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, pp. 26–8, 1962.

Frequency Distribution

The tabulation of raw data obtained by dividing it into CLASSES of some size and computing the number of data elements (or their fraction out of the total) falling within each pair of CLASS BOUNDARIES. The following table shows the frequency distribution of the data set illustrated by the histogram below.



class interval	class mark	absolute frequency	relative frequency	cumulative absolute frequency	relative cumulative frequency
0.00–9.99	5	1	0.01	1	0.01
10.00–9.99	15	3	0.03	4	0.04
20.00–9.99	25	8	0.08	12	0.12
30.00–9.99	35	18	0.18	30	0.30
40.00–9.99	45	24	0.24	54	0.54
50.00–9.99	55	22	0.22	76	0.76
60.00–9.99	65	15	0.15	91	0.91
70.00–9.99	75	8	0.08	99	0.99
80.00–9.99	85	0	0.00	99	0.99
90.00–9.99	95	1	0.01	100	1.00

Fresnel Integrals

In physics, the Fresnel integrals are most often defined by

$$C(u) + iS(u) \equiv \int_0^u e^{i\pi x^2/2}\,dx$$
$$= \int_0^u \cos\left(\tfrac{1}{2}\pi x^2\right)dx + i\int_0^u \sin\left(\tfrac{1}{2}\pi x^2\right)dx, \qquad (1)$$

so

$$C(u) \equiv \int_0^u \cos\left(\tfrac{1}{2}\pi x^2\right)dx \qquad (2)$$

$$S(u) \equiv \int_0^u \sin\left(\tfrac{1}{2}\pi x^2\right)dx. \qquad (3)$$

The Fresnel integrals are implemented in *Mathematica* as `FresnelC[z]` and `FresnelC[z]`
They satisfy

$$C(\pm\infty) = -\tfrac{1}{2} \tag{4}$$

$$S(\pm\infty) = \tfrac{1}{2}. \tag{5}$$

Related functions are defined as

$$C_1(z) \equiv \sqrt{\frac{2}{\pi}}\int_0^x \cos t^2 dt \tag{6}$$

$$S_1(z) \equiv \sqrt{\frac{2}{\pi}}\int_0^x \sin t^2 dt \tag{7}$$

$$C_2(z) \equiv \frac{1}{\sqrt{2\pi}}\int \frac{\cos t}{\sqrt{t}} dt \tag{8}$$

$$S_2(z) \equiv \frac{1}{\sqrt{2\pi}}\int \frac{\sin t}{\sqrt{t}} dt. \tag{9}$$

An asymptotic expansion for $x \gg 1$ gives

$$C(u) \approx \frac{1}{2} + \frac{1}{\pi u}\sin\left(\tfrac{1}{2}\pi u^2\right) \tag{10}$$

$$S(u) \approx \frac{1}{2} - \frac{1}{\pi u}\cos\left(\tfrac{1}{2}\pi u^2\right). \tag{11}$$

Therefore, as $u \to \infty$, $C(u) = 1/2$ and $S(u) = 1/2$. The Fresnel integrals are sometimes alternatively defined as

$$x(t) = \int_0^t \cos(v^2) dv \tag{12}$$

$$y(t) = \int_0^t \sin(v^2) dv. \tag{13}$$

Letting $x = v^2$ so $dx = 2v\ dv = 2\sqrt{x}\ dv$, and $dv = x^{-1/2} dx/2$

$$x(t) = \tfrac{1}{2}\int_0^{\sqrt{t}} x^{-1/2} \cos x\, dx \tag{14}$$

$$y(t) = \tfrac{1}{2}\int_0^{\sqrt{t}} x^{-1/2} \sin x\, dx. \tag{15}$$

In this form, they have a particularly simple expansion in terms of SPHERICAL BESSEL FUNCTIONS OF THE FIRST KIND. Using

$$j_0(x) = \frac{\sin x}{x} \tag{16}$$

$$n_1(x) = -j_{-1}(x) = -\frac{\cos x}{x}, \tag{17}$$

where $n_1(x)$ is a SPHERICAL BESSEL FUNCTION OF THE SECOND KIND

$$x(t^2) = -\tfrac{1}{2}\int_0^t n_1(x) x^{1/2} dx$$

$$= \tfrac{1}{2}\int_0^t j_{-1}(x) x^{1/2} dx = x^{1/2}\sum_{n=0}^{\infty} j_{2n}(x) \tag{18}$$

$$y(t^2) = \tfrac{1}{2}\int_0^t j_0(x) x^{1/2} dx$$

$$= x^{1/2}\sum_{n=0}^{\infty} j_{2n+1}(x). \tag{19}$$

Frey Curve

Let $a^p + b^p = c^p$ be a solution to FERMAT'S LAST THEOREM. Then the corresponding Frey curve is

$$y^2 = x(x - a^p)(x + b^p). \quad (1)$$

Frey showed that such curves cannot be MODULAR, so if the TANIYAMA-SHIMURA CONJECTURE were true, Frey curves couldn't exist and FERMAT'S LAST THEOREM would follow with b EVEN and $a \equiv -1 \pmod 4$. Frey curves are SEMISTABLE. Invariants include the DISCRIMINANT

$$(a^p - 0)^2(-b^p - 0)[a^p - (-b)^p]^2 = a^{2p}b^{2p}c^{2p}. \quad (2)$$

The MINIMAL DISCRIMINANT is

$$\Delta = 2^{-8}a^{2p}b^{2p}c^{2p}, \quad (3)$$

the CONDUCTOR is

$$N = \prod_{l|abc} l, \quad (4)$$

and the J-INVARIANT is

$$j = \frac{2^8(a^{2p} + b^{2p} + a^p b^p)^3}{a^{2p}b^{2p}c^{2p}} = \frac{2^8(c^{2p} - b^p c^p)^3}{(abc)^{2p}}. \quad (5)$$

Friendly Giant Group

MONSTER GROUP

Friendly Number

AMICABLE PAIR, FRIENDLY NUMBER

Friendly Pair

Define

$$\sum(n) \equiv \frac{\sigma(n)}{n},$$

where $\sigma(n)$ is the DIVISOR FUNCTION. Then a PAIR of distinct numbers (k, m) is a friendly pair (and k is said to be a FRIEND of m) if

$$\sum(k) = \sum(m).$$

For example, (4320, 4680) are a friendly pair, since $\sigma(4320) = 15120$, $\sigma(4680) = 16380$, and

$$\sum(4320) \equiv \frac{15120}{4320} = \frac{7}{2}$$

$$\sum(4680) \equiv \frac{16380}{4680} = \frac{7}{2}.$$

The first few friendly pairs, ordered by smallest maximum element are (6, 28), (30, 140), (80, 200), (40, 224), (12, 234), (84, 270), (66, 308), ... (Sloane's A050972 and A050973).

Numbers which do not have FRIENDS are called SOLITARY NUMBERS. A sufficient (but not necessary) condition for n to be a SOLITARY NUMBER is that $(\sigma(n), n) = 1$, where (a, b) is the GREATEST COMMON DIVISOR of a and b.

Hoffman (1998, p. 45) uses the term "friendly numbers" to describe AMICABLE PAIRS.

Frieze Pattern

In general, a frieze consists of repeated copies of a single motif.

$$\begin{matrix} & b & \\ a & & d \\ & c & \end{matrix}$$

Conway and Guy (1996) define a frieze pattern as an arrangement of numbers at the intersection of two sets of perpendicular diagonals such that $a+d=b+c+1$ (for an additive frieze pattern) or $ad=bc+1$ (for a multiplicative frieze pattern) in each diamond.

Steinbach, P. *Field Guide to Simple Graphs.* Albuquerque, NM: Design Lab, 1990.

Frobenius Map

A map $x \mapsto x^p$ where p is a PRIME.

Frobenius Method

If x_0 is an ordinary point of the ORDINARY DIFFERENTIAL EQUATION, expand y in a TAYLOR SERIES about x_0, letting

$$y=\sum_{n=0}^{\infty} a_n x^n. \quad (1)$$

Plug y back into the ODE and group the COEFFICIENTS by POWER. Now, obtain a RECURRENCE RELATION for the nth term, and write the TAYLOR SERIES in terms of the a_ns. Expansions for the first few derivatives are

$$y=\sum_{n=0}^{\infty} a_n x^n \quad (2)$$

$$y'=\sum_{n=1}^{\infty} n a_n x^{n-1}=\sum_{n=0}^{\infty}(n+1)a_{n+1}x^n \quad (3)$$

$$y''=\sum_{n=2}^{\infty} n(n-1)a_n x^{n-2}=\sum_{n=0}^{\infty}(n+2)(n+1)a_{n+2}x^n. \quad (4)$$

If x_0 is a regular singular point of the ORDINARY DIFFERENTIAL EQUATION,

$$P(x)y''+Q(x)y'+R(x)y=0, \quad (5)$$

solutions may be found by the Frobenius method or by expansion in a LAURENT SERIES. In the Frobenius method, assume a solution OF THE FORM

$$y=x^k\sum_{n=0}^{\infty} a_n x^n, \quad (6)$$

so that

$$y=x^k\sum_{n=0}^{\infty} a_n x^n=\sum_{n=0}^{\infty} a_n x^{n+k} \quad (7)$$

$$y'=\sum_{n=0}^{\infty} a_n(n+k)x^{k+n-1} \quad (8)$$

$$y''=\sum_{n=0}^{\infty} a_n(n+k)(n+k-1)x^{k+n-2}. \quad (9)$$

Now, plug y back into the ODE and group the COEFFICIENTS by POWER to obtain a recursion FORMULA for the a_nth term, and then write the TAYLOR SERIES in terms of the a_ns. Equating the a_0 term to 0 will produce the so-called INDICIAL EQUATION, which will give the allowed values of k in the TAYLOR SERIES.

FUCHS'S THEOREM guarantees that at least one POWER SERIES solution will be obtained when applying the Frobenius method if the expansion point is an ordinary, or regular, SINGULAR POINT. For a regular SINGULAR POINT, a LAURENT SERIES expansion can also be used. Expand y in a LAURENT SERIES, letting

$$y=c_{-n}x^{-n}+\cdots+c_0+c_1x+\cdots+c_nx^n+\cdots \quad (10)$$

Plug y back into the ODE and group the COEFFICIENTS by POWER. Now, obtain a recurrence FORMULA for the c_nth term, and write the TAYLOR EXPANSION in terms of the c_ns.

Frobenius Pseudoprime

Let $f(x)$ be a MONIC POLYNOMIAL of degree d with discriminant Δ. Then an ODD INTEGER n with $(n, f(0)\Delta) = 1$ is called a Frobenius pseudoprime with respect to $f(x)$ if it passes a certain algorithm given by Grantham (1996). A Frobenius pseudoprime with respect to a POLYNOMIAL $f(x) \in \mathbb{Z}[x]$ is then a composite Frobenius probably prime with respect to the POLYNOMIAL $x - a$.

While 323 is the first LUCAS PSEUDOPRIME with respect to the Fibonacci polynomial $x^2 - x - 1$, the first Frobenius pseudoprime is 5777. If $f(x) = x^3 - rx^2 + sx - 1$, then any Frobenius pseudoprime n with respect to $f(x)$ is also a PERRIN PSEUDOPRIME. Grantham (1997) gives a test based on Frobenius pseudoprimes which is passed by COMPOSITE NUMBERS with probability at most 1/7710.

Fuchsian System

A system of linear differential equations

$$\frac{dy}{dz} = A(z)y,$$

with $A(z)$ an ANALYTIC $n \times n$ MATRIX, for which the MATRIX $A(z)$ is ANALYTIC in $\mathbb{C}\backslash\{a_1,\ldots,a_N\}$ and has a POLE of order 1 at a_j for $j=1$, ..., N. A system is Fuchsian IFF there exist $n \times n$ matrices B_1, ..., B_N with entries in $\mathbb{Z}$ such that

$$A(z) = \sum_{j=1}^N \frac{B_j}{z-a_j}$$

$$\sum_{j=1}^N B_j = v.$$

Fuglede's Conjecture

Fuglede (1974) conjectured that a domain Ω admits a SPECTRUM IFF it is possible to tile $\mathbb{R}^d$ by a family of translates of Ω. Fuglede proved the conjecture in the special case that the tiling set or the spectrum are lattice subsets of $\mathbb{R}^d$ and Iosevich *et al.* (1999) proved that no smooth symmetric convex body Ω with at least one point of nonvanishing GAUSSIAN CURVATURE can admit an orthogonal basis of exponentials. However, the general conjecture is still far from being proved (Iosevich *et al.* 1999).

Fuhrmann Center

The center of the FUHRMANN CIRCLE, given by the MIDPOINT of the line joining the NAGEL POINT and ORTHOCENTER (which forms a DIAMETER of the FUHRMANN CIRCLE).

See also FUHRMANN CIRCLE, NAGEL POINT, ORTHOCENTER

Fuhrmann Circle

The CIRCUMCIRCLE of the FUHRMANN TRIANGLE. The ORTHOCENTER H, NAGEL POINT Na, and at least six other noteworthy points lie on the Fuhrmann circle (Honsberger 1995, p. 49). In particular, HNa is a DIAMETER of the Fuhrmann circle. It also passes through the points T, U, and V which are a distance $2r$ along the ALTITUDES from the vertices, where r is the INRADIUS of ΔABC (Honsberger 1995, p. 52).

Fuhrmann's Theorem

Let the opposite sides of a convex CYCLIC HEXAGON be a, a', b, b', c, and c', and let the DIAGONALS e, f, and g be so chosen that a, a', and e have no common VERTEX (and likewise for b, b', and f), then

$$efg = aa'e + bb'f + cc'g + abc + a'b'c'.$$

This is an extension of PTOLEMY'S THEOREM to the HEXAGON.

Full Angle

An ANGLE equal to 360°.

See also ACUTE ANGLE, ANGLE, OBTUSE ANGLE, REFLEX ANGLE, RIGHT ANGLE, STRAIGHT ANGLE

Full Reptend Prime

A PRIME p for which $1/p$ has a maximal period DECIMAL EXPANSION of $p-1$ DIGITS, sometimes called a long prime (Conway and Guy 1996, pp. 157–63 and 166–71). A prime is full reptend IFF 10 is a PRIMITIVE ROOT modulo p. No general method is known for finding full reptend primes. The first few numbers with maximal decimal expansions are 7, 17, 19, 23, 29, 47, 59, 61, 97, ... (Sloane's A001913).

Full Width at Half Maximum

The full width at half maximum (FWHM) is a parameter commonly used to describe the width of a "bump" on a curve or function. It is given by the distance between points on the curve at which the function reaches half its maximum value. The following table gives the analytic and numerical full widths for several common curves.

Function	Formula	FWHM
Bartlett	$1-\frac{\lvert x\rvert}{a}$	a
Blackman		$0.810957a$
Connes	$\left(1-\frac{x^2}{a^2}\right)$	$\sqrt{4-2\sqrt{2}a}$
Cosine	$\cos\left(\frac{\pi x}{2a}\right)$	$\frac{4}{3}a$
Gaussian	$e^{-x2/(2\sigma^2)}$	$2\sqrt{2\ln 2}\sigma$
Hamming		$1.05543a$
Hanning		a
Lorentzian	$\frac{\frac{1}{2}\Gamma}{x^2+\left(\frac{1}{2}\Gamma\right)^2}$	Γ
Welch	$1-\frac{x^2}{a^2}$	$\sqrt{2}a$

GEODESIC DOME

Function

A relation which uniquely associates members of one SET with members of another SET. More formally, a function from A to B is an object f such that every $a \in A$ is uniquely associated with an object $f(a) \in B$. A function is therefore a MANY-TO-ONE (or sometimes ONE-TO-ONE) relation. Examples of functions include $\sin x$ (MANY-TO-ONE), x (ONE-TO-ONE), x^2 (two-to-one except for the single point $x=0$), etc. The term "MAP" is synonymous with function.

Several notations are commonly used to represent functions. The most rigorous notation is $f: x \to f(x)$, which specifies that f is function acting upon a single number x (i.e., f is a univariate, or one-variable, function) and returning a value $f(x)$. To be even more precise, a notation like "$f: \mathbb{R} \to \mathbb{R}$, where $f(x)=x^2$" is sometimes used to explicitly specify the domain and range of the function. The slightly different "maps to"

notation $f : x \mapsto f(x)$ is sometimes also used when the function is explicitly considered as a "map."

Generally speaking, the symbol f refers to the function itself, while $f(x)$ refers to the *value* taken by the function when evaluated at a point x. However, especially in more introductory texts, the notation $f(x)$ is commonly used to refer to the *function* f itself (as opposed to the value of the function evaluated at x). In this context, the argument x is considered to be a DUMMY VARIABLE whose presence indicates that the function f takes a single argument (as opposed to $f(x, y)$, etc.). While this notation is deprecated by professional mathematicians, it is the more familiar one for most nonprofessionals. Therefore, unless indicated otherwise by context, the notation $f(x)$ is taken in this work to be a shorthand for the more rigorous $f : x \to f(x)$.

Poincaré remarked with regard to the proliferation of pathological functions, "Formerly, when one invented a new function, it was to further some practical purpose; today one invents them in order to make incorrect the reasoning of our fathers, and nothing more will ever be accomplished by these inventions."

Function Element

A function element is an ORDERED PAIR (f, U) where U is a disk $D(Z_0, r)$ and f is an ANALYTIC FUNCTION defined on U. If W is an OPEN SET, then a function element in W is a pair (f, U) such that $U \subseteq W$.

Function of the First Kind

FIRST KIND

Function of the Second Kind

SECOND KIND

Function of the Third Kind

THIRD KIND

Function Space

$f(I)$ is the collection of all real-valued continuous functions defined on some interval I. $f^{(n)}(I)$ is the collection of all functions $\in f(I)$ with continuous nth DERIVATIVES. A function space is a TOPOLOGICAL VECTOR SPACE whose "points" are functions.

See also FUNCTIONAL, FUNCTIONAL ANALYSIS, OPERATOR

Functional

A functional is a real-valued function on a VECTOR SPACE V, usually of functions. For example, the ENERGY functional on the UNIT DISK D assigns a number to any differentiable function $f : D \to \mathbb{R}$,

$$E(f) : \int D\|\nabla f\|^2 dA.$$

For the functional to be continuous, it is necessary for the VECTOR SPACE V of functions to have an appropriate TOPOLOGY. The widespread use of functionals in applications, such as the CALCULUS OF VARIATIONS, gave rise to FUNCTIONAL ANALYSIS.

The reason the term "functional" is used is because V can be a space of functions, e.g.,

$$V = \{f : [0, 1] \to \mathbb{R} \text{ such that } f \text{ is continuous}\}$$

in which case $T(f) = f(0)$ is a LINEAR FUNCTIONAL on V.

Functional Analysis

A branch of mathematics concerned with infinite dimensional spaces (mainly FUNCTION SPACES) and mappings between them. The SPACES may be of different, and possibly INFINITE, DIMENSIONS. These

mappings are called OPERATORS or, if the range is on the REAL line or in the COMPLEX PLANE, FUNCTIONALS.

See also FUNCTIONAL, FUNCTIONAL EQUATION, GENERALIZED FUNCTION, OPERATOR

Functional Calculus

An early name for CALCULUS OF VARIATIONS. The term is also sometimes used in place of PREDICATE CALCULUS.

Functional Congruence

A CONGRUENCE OF THE FORM

$$f(x) \equiv g(x) (\bmod n)$$

where $f(x)$ and $g(x)$ are both INTEGER POLYNOMIALS. Functional congruences are sometimes also called "identical congruences" (Nagell 1951, p. 74).

See also CONGRUENCE

Functional Derivative

A generalization of the concept of the DERIVATIVE to GENERALIZED FUNCTIONS.

Functional Distribution

GENERALIZED FUNCTION

Functional Equation

An equation OF THE FORM $f(x, y, ...) = 0$, where f contains a finite number of independent variables, known functions, and unknown functions which are to be solved for. Many properties of functions can be determined by studying the types of functional equations they satisfy. For example, the GAMMA FUNCTION $\Gamma(z)$ satisfies the functional equations

$$\Gamma(1+z) = z\Gamma(z)$$

$$\Gamma(1-z) = -z\Gamma(-z).$$

Fundamental Forms

There are three types of so-called fundamental forms. The most important are the first and second (since the third can be expressed in terms of these). The fundamental forms are extremely important and useful in determining the metric properties of a surface, such as LINE ELEMENT, AREA ELEMENT, NORMAL CURVATURE, GAUSSIAN CURVATURE, and MEAN CURVATURE. Let M be a REGULAR SURFACE with $\mathbf{v}_P, \mathbf{w}_P$ points in the TANGENT SPACE $M_\mathbf{P}$ of M. Then the FIRST FUNDAMENTAL FORM is the INNER PRODUCT of tangent vectors,

$$\mathrm{I}(\mathbf{v_P}, \mathbf{w_P}) = \mathbf{v_P} \cdot \mathbf{w_P}. \tag{1}$$

For $M \in \mathbb{R}^3$, the SECOND FUNDAMENTAL FORM is the symmetric bilinear form on the TANGENT SPACE $M_\mathbf{P}$,

$$\mathbf{II}(\mathbf{v_p}, \mathbf{w_p}) = S(\mathbf{v_p}) \cdot \mathbf{w_p}, \tag{2}$$

where S is the SHAPE OPERATOR. The THIRD FUNDAMENTAL FORM is given by

$$\mathbf{III}(\mathbf{v_p}, \mathbf{w_p}) = S(\mathbf{v_p}) \cdot S(\mathbf{w_p}). \tag{3}$$

The FIRST and SECOND FUNDAMENTAL FORMS satisfy

$$\mathbf{I}(a\mathbf{X}_u + b\mathbf{X}_v, a\mathbf{X}_u + b\mathbf{X}_v) = Ea^2 + 2Fab + Gb^2 \tag{4}$$

$$\mathbf{II}(a\mathbf{X}_u + b\mathbf{X}_v, a\mathbf{X}_u + b\mathbf{X}_v) = ea^2 + 2fab + gb^2 \tag{5}$$

where $x : U \to \mathbb{R}^3$ is a REGULAR PATCH and $\mathbf{x}_u$ and $\mathbf{x}_v$ are the partial derivatives of $\mathbf{x}$ with respect to parameters u and v, respectively. Their ratio is simply the NORMAL CURVATURE

$$k(\mathbf{v_p}) = \frac{\mathbf{II}(\mathbf{v_p})}{\mathbf{I}(\mathbf{v_p})} \tag{6}$$

for any nonzero TANGENT VECTOR. The third fundamental form is given in terms of the first and second forms by

$$\mathbf{III} - 2H\mathbf{II} + K\mathbf{I} = 0, \tag{7}$$

where H is the MEAN CURVATURE and K is the GAUSSIAN CURVATURE.

The first fundamental form (or LINE ELEMENT) is given explicitly by the RIEMANNIAN METRIC

$$ds^2 = Edu^2 + 2Fdudv + Gdv^2. \tag{8}$$

It determines the ARC LENGTH of a curve on a surface. The coefficients are given by

$$E = \mathbf{x}_{uu} = \left|\frac{\partial \mathbf{x}}{\partial u}\right|^2 \tag{9}$$

$$F = \mathbf{x}_{uv} = \frac{\partial \mathbf{x}}{\partial u} \cdot \frac{\partial \mathbf{x}}{\partial v} \tag{10}$$

$$G = \mathbf{x}_{vv} = \left|\frac{\partial \mathbf{x}}{\partial v}\right|^2. \tag{11}$$

The coefficients are also denoted $g_{uu} = E$, $g_{uv} = F$, and $g_{vv} = G$. In CURVILINEAR COORDINATES (where $F = 0$), the quantities

$$h_u \equiv \sqrt{g_{uu}} = \sqrt{E} \tag{12}$$

$$h_v \equiv \sqrt{g_{vv}} = \sqrt{G} \tag{13}$$

are called SCALE FACTORS.

The second fundamental form is given explicitly by

$$e\ du^2 + 2f\ du\mathrm{d}v + g\ dv^2 \tag{14}$$

where

$$e = \sum_i X_i \frac{\partial^2 x_i}{\partial u^2} \tag{15}$$

$$f = \sum_i X_i \frac{\partial^2 x_i}{\partial u \partial v} \tag{16}$$

$$g = \sum_i X_i \frac{\partial^2 x_i}{\partial v^2}, \tag{17}$$

and X_i are the DIRECTION COSINES of the surface normal. The second fundamental form can also be written

$$e = -\mathbf{N}_u \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uu} \tag{18}$$

$$f = -\mathbf{N}_v \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uv} = \mathbf{N}_{vu} \cdot \mathbf{x}_{vu}$$

$$= \mathbf{N}_u \cdot \mathbf{x}_v \tag{19}$$

$$g = -\mathbf{N}_v \cdot \mathbf{x}_v = \mathbf{N} \cdot \mathbf{x}_{vv}, \tag{20}$$

where $\mathbf{N}$ is the NORMAL VECTOR, or

$$e = \frac{\det(\mathbf{x}_{uu}\mathbf{x}_u\mathbf{x}_v)}{\sqrt{EG - F^2}} \tag{21}$$

$$f = \frac{\det(\mathbf{x}_{uv}\mathbf{x}_u\mathbf{x}_v)}{\sqrt{EG - F^2}} \tag{22}$$

$$g = \frac{\det(\mathbf{x}_{vv}\mathbf{x}_u\mathbf{x}_v)}{\sqrt{EG - F^2}}. \tag{23}$$

Fundamental Group

The fundamental group of an ARCWISE-CONNECTED set X is the GROUP formed by the sets of EQUIVALENCE CLASSES of the set of all LOOPS, i.e., paths with initial and final points at a given BASEPOINT p, under the EQUIVALENCE RELATION of HOMOTOPY. The IDENTITY ELEMENT of this group is the set of all paths HOMOTOPIC to the degenerate path consisting of the point p. The fundamental groups of HOMEOMORPHIC spaces are ISOMORPHIC. In fact, the fundamental group only depends on the HOMOTOPY TYPE of X. The fundamental group of a TOPOLOGICAL SPACE was introduced by Poincaré (Munkres 1993, p. 1).

The following is a table of the fundamental group for some common spaces, where π_1 denotes the fundamental group, H_1 is the first integral HOMOLOGY, $\times$ denotes the GROUP DIRECT PRODUCT, $\mathbb{Z}$ denotes the RING of integers, and $\mathbb{Z}_n$ is the CYCLIC GROUP of order n.

space	symbol	π_1	H_1
CIRCLE	$\mathbb{S}^1$	$\mathbb{Z}$	$\mathbb{Z}$
figure eight		$\mathbb{Z} \coprod \mathbb{Z}$	$\mathbb{Z} \times \mathbb{Z}$
SPHERE	$\mathbb{S}^2$	0	0
TORUS	$\mathbb{T}$	$\mathbb{Z} \times \mathbb{Z}$	$\mathbb{Z} \times \mathbb{Z}$
TORUS of genus g	Σ_g	F_g	$\mathbb{Z}^{2g}$
REAL PROJECTIVE PLANE	$\mathbb{RP}^2$	$\mathbb{Z}_2$	$\mathbb{Z}_2$
KLEIN BOTTLE		$\frac{\mathbb{Z} \coprod \mathbb{Z}}{(aba^{-1}b)}$	$\mathbb{Z} \times \mathbb{Z}_2$
COMPLEX PROJECTIVE SPACE	$\mathbb{CP}^n$	0	0
n-torus	$\mathbb{T}^n$	$\mathbb{Z}^n$	$\mathbb{Z}^n$

The group product $a * b$ of LOOP a and LOOP b is given by the path of a followed by the path of b. The identity element is represented by the constant path, and the inverse of a is given by traversing a in the opposite direction. The fundamental group is independent of the choice of basepoint because any loop through p is HOMOTOPIC to a loop through any other point q. So it makes sense to say the "fundamental group of X."

The diagram above shows that a loop followed by the opposite loop is homotopic to the constant loop, i.e., the identity. That is, it starts by traversing the path a, and then turns around and goes the other way, a^{-1}. The composition is deformed, or homotoped, to the constant path, along the original path a.

A space with a trivial fundamental group (i.e., every loop is homotopic to the constant loop), is called SIMPLY CONNECTED. For instance, any CONTRACTIBLE space, like EUCLIDEAN SPACE, is simply connected. The SPHERE is SIMPLY CONNECTED, but not CONTRACTIBLE. By definition, the UNIVERSAL COVER $\tilde{X}$ is simply connected, and loops in X lift to paths in $\tilde{X}$. The lifted paths in the universal cover define the DECK TRANSFORMATIONS, which form a GROUP isomorphic to the fundamental group.

The underlying set of the fundamental group of X is the set of based HOMOTOPY CLASSES from the circle to X, denoted $[\mathbb{S}^1, X]$. For general spaces X and Y, there is no natural group structure on $[X, Y]$, but when there is, X is called a H-SPACE. Besides the circle, every SPHERE $\mathbb{S}^n$ is a H-SPACE, defining the HOMOTOPY GROUPS. In general, the fundamental group is NON-ABELIAN. However, the higher HOMOTOPY GROUPS are Abelian. In some special cases, the fundamental group is Abelian. For example, the

animation above shows that $a * b = b * a$ in the TORUS. The red path goes before the green path. The animation is a homotopy between the loop that goes around the inside first and the loop that goes around the outside first.

Since the first integral HOMOLOGY $H_1(X, \mathbb{Z})$ of X is also represented by loops, which are the only 1-dimensional objects with no boundary, there is a GROUP HOMOMORPHISM

$$\alpha : \pi_1(X) \to H_1(X, \mathbb{Z}),$$

which is SURJECTIVE. In fact, the KERNEL of α is the COMMUTATOR SUBGROUP and α is called ABELIANIZATION.

The fundamental group of X can be computed using VAN KAMPEN'S THEOREM, when X can be written as a union $X = \cup_i X_i$ of spaces whose fundamental groups are known.

When $f : X \to Y$ is a continuous map, then the fundamental group pushes forward. That is, there is a map $f_* : \pi_1(X) \to \pi_1(Y)$ defined by taking the image of loops from X. The pushforward is natural, i.e., $(f \circ g)_* = f_* \circ g_*$ whenever the composition of two maps is defined.

Fundamental Homology Class

FUNDAMENTAL CLASS

Fundamental Lemma of Calculus of Variations

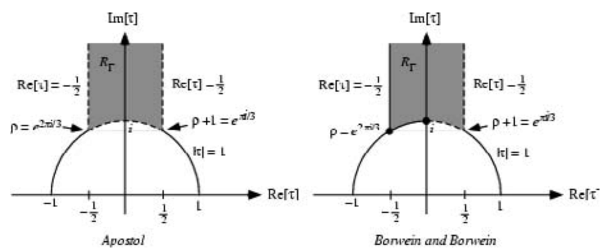
If

$$\int_a^b M(x)h(x)\,dx = 0$$

$\forall h(x)$ with CONTINUOUS second PARTIAL DERIVATIVES, then

$$M(x) = 0$$

on the OPEN INTERVAL (a, b).



Fundamental Polytope

PRIMITIVE POLYTOPE

Fundamental Region

Let G be a SUBGROUP of the MODULAR GROUP GAMMA. Then an open subset R_G of the UPPER HALF-PLANE H is called a fundamental region of G if

1. No two distinct points of R_G are equivalent under G,
2. If $\tau \in H$, then there is a point τ' in the closure of R_G such that τ' is equivalent to τ under G.

A fundamental region R_Γ of the MODULAR GROUP GAMMA is given by $\tau \in H$ such that $|\tau| > 1$ and $|\tau + \bar{\tau}| < 1$, illustrated above, where $\bar{\tau}$ is the COMPLEX CONJUGATE of τ (Apostol 1997, p. 31). Borwein and Borwein (1987, p. 113) define the boundaries of the region slightly differently by including the boundary points with $\Re[\tau] \leq 0$.

Fundamental Theorem of Algebra

Every POLYNOMIAL EQUATION having COMPLEX COEFFICIENTS and degree ≥ 1 has at least one COMPLEX ROOT. This theorem was first proven by Gauss. It is equivalent to the statement that a POLYNOMIAL $P(z)$ of degree n has n values z_i (some of them possibly degenerate) for which $P(z_i) = 0$. Such values are called POLYNOMIAL ROOTS. An example of a POLYNOMIAL with a single ROOT of multiplicity > 1 is $z^2 - 2z + 1 = (z-1)(z-1)$, which has $z = 1$ as a ROOT of multiplicity 2.

For RINGS more general than the complex polynomials $\mathbb{C}[x]$, there does not necessarily exist a unique factorization. However, a PRINCIPAL RING is a structure for which the proof of the unique factorization property is sufficiently easy while being quite general and common.

Fundamental Theorem of Gaussian Quadrature

The ABSCISSAS of the N-point GAUSSIAN QUADRATURE FORMULA are precisely the ROOTS of the ORTHOGONAL POLYNOMIAL for the same INTERVAL and WEIGHTING FUNCTION.

See also GAUSSIAN QUADRATURE

Fundamental Theorem of Genera

Consider $h_+(d)$ proper equivalence classes of forms with discriminant d equal to the field discriminant, then they can be subdivided equally into 2^{r-1} genera of $h_+(d)/2^{r-1}$ forms which form a SUBGROUP of the proper equivalence class group under composition (Cohn 1980, p. 224), where r is the number of distinct prime divisors of d. This theorem was proved by Gauss in 1801.

Fundamental Theorems of Calculus

The first fundamental theorem of calculus states that, if f is CONTINUOUS on the CLOSED INTERVAL $[a, b]$ and F is the ANTIDERIVATIVE (INDEFINITE INTEGRAL) of f on $[a, b]$, then

$$\int_a^b f(x)dx = F(b) - F(a). \tag{1}$$

The second fundamental theorem of calculus lets f be CONTINUOUS on an OPEN INTERVAL I and lets a be any point in I. If F is defined by

$$F(x) = \int_a^x f(t)dt, \tag{2}$$

then

$$F'(x) = f(x) \tag{3}$$

at each point in I.

The fundamental theorem of calculus along curves states that if $f(z)$ has a CONTINUOUS ANTIDERIVATIVE $F(z)$ in a region R containing a parameterized curve $\gamma : z = z(t)$ for $\alpha \le t \le \beta$, then

$$\int_\gamma f(z)dz = F(z(\beta)) - F(z(\alpha)). \tag{4}$$

Fundamental Unit

In a REAL QUADRATIC FIELD, there exists a special UNIT η known as the fundamental unit such that all units ρ are given by $\rho = \pm\eta^m$, for $m = 0, \pm 1, \pm 2, \ldots$. The notation ε_0 is sometimes used instead of η (Zucker and Robertson 1976). The fundamental units for REAL QUADRATIC FIELDS $\mathbb{Q}(\sqrt{D})$ may be computed from the fundamental solution of the PELL EQUATION

$$T^2 - DU^2 = \pm 4,$$

where the sign is taken such that the solution (T, U) has smallest possible positive T (LeVeque 1977; Cohn 1980, p. 101; Hua 1982; Borwein and Borwein 1986, p. 294). If the positive sign is taken, then one solution is simply given by $(T, U) = (2x, 2y)$, where (x, y) is the solution to the PELL EQUATION

$$x^2 - Dy^2 = 1$$

However, this need not be the *minimal* solution. For example, the solution to Pell equation

$$x^2 - 21y^2 = 1$$

is $(x, y) = (55, 12)$, so $(T, U) = (2x, 2y) = (110, 24)$, but $(T, U) = (5, 1)$ is the minimal solution. Given a minimal (T, U) (Sloane's A048941 and A048942), the fundamental unit is given by

$$\eta = \frac{1}{2}(T + U\sqrt{D})$$

(Cohn 1980, p. 101).

The following table gives fundamental units for small D.

D	$\eta(D)$	D	$\eta(D)$
2	$1+\sqrt{2}$	54	$485+66\sqrt{54}$
3	$2+\sqrt{3}$	55	$89+12\sqrt{55}$
5	$\frac{1}{2}(1+\sqrt{5})$	56	$15+2\sqrt{56}$
6	$5+2\sqrt{6}$	57	$151+20\sqrt{57}$
7	$8+3\sqrt{7}$	58	$99+13\sqrt{58}$
8	$\frac{1}{2}(1+2\sqrt{8})$	59	$530+69\sqrt{59}$
10	$3+\sqrt{10}$	60	$\frac{1}{2}(8+\sqrt{60})$
11	$10+3\sqrt{11}$	61	$\frac{1}{2}(39+5\sqrt{61})$
12	$7+2\sqrt{12}$	62	$63+8\sqrt{62}$
13	$\frac{1}{2}(3+\sqrt{13})$	63	$8+\sqrt{63}$
14	$15+4\sqrt{14}$	65	$8+\sqrt{65}$
15	$4+\sqrt{15}$	66	$65+8\sqrt{66}$
17	$4+\sqrt{17}$	67	$48842+5967\sqrt{67}$
18	$17+4\sqrt{18}$	68	$\frac{1}{2}(8+\sqrt{68})$
19	$170+39\sqrt{19}$	69	$\frac{1}{2}(25+3\sqrt{69})$
20	$\frac{1}{2}(4+\sqrt{20})$	70	$251+30\sqrt{70}$
21	$\frac{1}{2}+(5+\sqrt{21})$	71	$3480+413\sqrt{71}$
22	$197+42\sqrt{22}$	72	$17+2\sqrt{72}$
23	$24+5\sqrt{23}$	73	$1068+125\sqrt{73}$
24	$5+\sqrt{24}$	74	$43+5\sqrt{74}$

Funnel

The funnel surface is a REGULAR SURFACE and SURFACE OF REVOLUTION defined by the Cartesian equation

$$Z = \frac{1}{2}\ln(x^2 + y^2) \tag{1}$$

and the PARAMETRIC EQUATIONS

$$x(u, v) = u \cos v \tag{2}$$

$$y(u, v) = u \sin v \tag{3}$$

$$z(u, v) = \ln u \tag{4}$$

for $u > 0$ and $v \in [0, 2\pi)$. The coefficients of the FIRST FUNDAMENTAL FORM are

$$E = 1 + \frac{1}{u^2} \tag{5}$$

$$F = 0 \tag{6}$$

$$G = u^2, \tag{7}$$

the coefficients of the SECOND FUNDAMENTAL FORM are

$$e = -\frac{1}{u\sqrt{1+u^2}} \tag{8}$$

$$f = 0 \tag{9}$$

$$g = \frac{u}{\sqrt{1+u^2}}, \tag{10}$$

the AREA ELEMENT is

$$dA = \sqrt{1+u^2}\, du \wedge dv, \tag{11}$$

and the Gaussian and mean curvatures are

$$K = -\frac{1}{(1+u^2)^2} \tag{12}$$

$$H = \frac{1}{2u(1+u^2)^{3/2}}. \tag{13}$$

Both the surface area and volume of the solid are infinite.

Gabriel's Horn

The surface of revolution of the function $y = 1/x$ about the x-axis for $x \geq 1$. It has finite volume

$$V = \int_1^\infty \pi y^2\, dx = \pi \int_1^\infty \frac{dx}{x^2}$$
$$= \pi \left[-\frac{1}{x} \right]_1^\infty = \pi[0 - (-1)] = \pi,$$

but infinite surface area, since

$$S = \int_1^\infty 2\pi y \sqrt{1 + y'^2}\, dx$$
$$> 2\pi \int_1^\infty y\, dx = 2\pi \int_1^\infty \frac{dx}{x} = 2\pi[\ln x]_1^\infty$$
$$= 2\pi[\ln \infty - 0] = \infty.$$

This leads to the paradoxical consequence that while Gabriel's horn can be filled up with π cubic units of paint, an infinite number of square units of paint are needed to cover its surface!

Galois Extension

This entry contributed by NICOLAS BRAY

An extension F of a field K is said to be a Galois extension of K, if for every $x \in F - K$, there is an element of the GALOIS GROUP of the extension which does not fix x (i.e., there exits $\sigma \in \mathrm{Aut}_K F$ such that $\sigma(x) \neq x$)).

See also GALOIS EXTENSION FIELD

Galois Extension Field

If K is the SPLITTING FIELD over a FIELD F of a separable POLYNOMIAL $f(x)$, then the EXTENSION FIELD K/F is a Galois extension field.

See also EXTENSION FIELD, GALOIS EXTENSION, SPLITTING FIELD

References

Dummit, D. S. and Foote, R. M. *Abstract Algebra, 2nd ed.* Englewood Cliffs, NJ: Prentice-Hall, pp. 475–76, 1998.

Galois Field

FINITE FIELD

Galois Group

Let L be a FIELD EXTENSION of K, denoted L/K, and let G be the set of AUTOMORPHISMS of L/K, that is, the set of AUTOMORPHISMS σ of L such that $\sigma(x) = x$ for every $x \in K$, so that K is fixed. Then G is a GROUP of transformations of L, called the Galois group of L/K.

The Galois group of $(\mathbb{C}/\mathbb{R})$ consists of the IDENTITY ELEMENT and COMPLEX CONJUGATION. These functions both take a given REAL to the same real.

See also ABHYANKAR'S CONJECTURE, FINITE GROUP, GROUP

Galois's Theorem

An algebraic equation is algebraically solvable IFF its GROUP is SOLVABLE. In order that an irreducible equation of PRIME degree be solvable by radicals, it is NECESSARY and SUFFICIENT that all its ROOTS be rational functions of two ROOTS.

See also ABEL'S IMPOSSIBILITY THEOREM, SOLVABLE GROUP

Galoisian

An algebraic extension E of F for which every IRREDUCIBLE POLYNOMIAL in F which has a single ROOT in E has *all* its ROOTS in E is said to be Galoisian. Galoisian extensions are also called algebraically normal.

Gambler's Ruin

Let two players each have a finite number of pennies (say, n_1 for player one and n_2 for player two). Now, flip one of the pennies (from either player), with each player having 50% probability of winning, and give the penny to the winner. Now repeat the process until one player has all the pennies.

If the process is repeated indefinitely, the probability that *one* of the two player will *eventually* lose all his pennies must be 100%. In fact, the chances P_1 and P_2 that players one and two, respectively, will be rendered penniless are

$$P_1 = \frac{n_2}{n_1 + n_2}$$

$$P_2 = \frac{n_1}{n_1 + n_2},$$

i.e., your chances of going bankrupt are equal to the ratio of pennies your opponent starts out to the total number of pennies.

Therefore, the player starting out with the smallest number of pennies has the greatest chance of going bankrupt. Even with equal odds, the longer you gamble, the greater the chance that the player starting out with the most pennies wins. Since casinos have more pennies than their individual patrons, this principle allows casinos to always come out ahead in the long run. And the common practice of playing games with odds skewed in favor

of the house makes this outcome just that much quicker.

Game

A game is defined as a conflict involving gains and losses between two or more opponents who follow formal rules. The study of games belongs to a branch of mathematics known as GAME THEORY.

Game Expectation

Let the elements in a PAYOFF MATRIX be denoted a_{ij}, where the is are player A's STRATEGIES and the js are player B's STRATEGIES. Player A can get at least

$$\min_{j \leq n} a_{ij} \tag{1}$$

for STRATEGY i. Player B can force player A to get no more than $\max_{j \leq m} a_{ij}$ for a STRATEGY j. The best STRATEGY for player A is therefore

$$\max_{i \leq m} \min_{j \leq n} a_{ij}, \tag{2}$$

and the best STRATEGY for player B is

$$\min_{j \leq n} \max_{i \leq m} a_{ij}. \tag{3}$$

In general,

$$\max_{i \leq m} \min_{j \leq n} a_{ij} \leq \min_{j \leq n} \max_{i \leq m} a_{ij}. \tag{4}$$

Equality holds only if a SADDLE POINT is present, in which case the quantity is called the VALUE of the game.

LIFE

Game Theory

A branch of MATHEMATICS and LOGIC which deals with the analysis of GAMES (i.e., situations involving parties with conflicting interests). In addition to the mathematical elegance and complete "solution" which is possible for simple games, the principles of game theory also find applications to complicated games such as cards, checkers, and chess, as well as real-world problems as diverse as economics, property division, politics, and warfare.

Gamma

GAMMA FUNCTION, INCOMPLETE GAMMA FUNCTION

Gamma Distribution

A general type of STATISTICAL DISTRIBUTION which is related to the BETA DISTRIBUTION and arises naturally in processes for which the waiting times between POISSON DISTRIBUTED events are relevant. Gamma distributions have two free parameters, labeled α and θ, a few of which are illustrated above.

Given a POISSON DISTRIBUTION with a rate of change λ, the DISTRIBUTION FUNCTION $D(x)$ giving the waiting times until the hth Poisson event is

$$\begin{aligned} D(x) = P(X \le x) = 1 - P(x > x) &= 1 - \sum_{k=0}^{h-1} \frac{(\lambda x)^k e^{-\lambda x}}{k!} \\ &= 1 - e^{-\lambda x} \sum_{k=0}^{h-1} \frac{(\lambda x)^k}{k!} = 1 - \frac{\Gamma(h,\ x\lambda)}{\Gamma(h)} \end{aligned} \tag{1}$$

for $x \in [0,\ \infty)$, where $\Gamma(x)$ is a complete GAMMA FUNCTION, and $\Gamma(a,\ x)$ an INCOMPLETE GAMMA FUNCTION. With h an integer, this distribution is a DISCRETE DISTRIBUTION known as the ERLANG DISTRIBUTION. The probability function $P(x)$ is then obtained by differentiating $D(x)$,

$$\begin{aligned} P(x) = D'(x) &= \lambda e^{-\lambda x} \sum_{k=0}^{h-1} \frac{(\lambda x)^k}{k!} - e^{-\lambda x} \sum_{k=0}^{h-1} \frac{k(\lambda x)^{k-1}\lambda}{k!} \\ &= \lambda e^{-\lambda x} + \lambda e^{-\lambda x} \sum_{k=1}^{h-1} \frac{(\lambda x)^k}{k!} - e^{-\lambda x} \sum_{k=1}^{h-1} \frac{k(\lambda x)^{k-1}\lambda}{k!} \\ &= \lambda e^{-\lambda x} - \lambda e^{-\lambda x} \sum_{k=1}^{h-1} \left[\frac{k(\lambda x)^{k-1}}{k!} - \frac{(\lambda x)^k}{k!} \right] \\ &= \lambda e^{-\lambda x} \left\{ 1 - \sum_{k=1}^{h-1} \left[\frac{(\lambda x)^{k-1}}{(k-1)!} - \frac{(\lambda x)^k}{k!} \right] \right\} \\ &= \lambda e^{-\lambda x} \left\{ 1 - \left[1 - \frac{(\lambda x)^{h-1}}{(h-1)!} \right] \right\} = \frac{\lambda(\lambda x)^{h-1}}{(h-1)!}\ e^{-\lambda x}. \end{aligned} \tag{2}$$

Now let $\alpha \equiv h$ (not necessarily an integer) and define $\theta \equiv 1/\lambda$ to be the time between changes. Then the above equation can be written

$$P(x)\ \frac{x^{\alpha-1} e^{-x/\theta}}{\Gamma(\alpha)\theta^\alpha} \tag{3}$$

for $x \in [0,\ \infty)$. The CHARACTERISTIC FUNCTION describing this distribution is

$$\phi(t) = \mathscr{F}\left\{ \frac{x^{-x/\theta} x^{\alpha-1}}{\Gamma(\alpha)\theta^\alpha} [\tfrac{1}{2}(1 + \operatorname{sgn} x)] \right\} = (1 - it\theta)^{-\alpha}, \tag{4}$$

where $\mathscr{F}[f]$ is the FOURIER TRANSFORM with parameters $a = b = 1$, and the MOMENT-GENERATING FUNCTION is

$$M(t) = \int_0^\infty \frac{e^{tx} x^{\alpha-1} e^{-x/\theta}\ dx}{\Gamma(\alpha)\theta^\alpha} = \int_0^\infty \frac{x^{\alpha-1} e^{-(1-\theta t)x/\theta}\ dx}{\Gamma(\alpha)\theta^\alpha}. \tag{5}$$

giving moments about 0 of

$$\mu'_r = \frac{\theta^r \Gamma(\alpha + r)}{\Gamma(\alpha)} \tag{6}$$

(Papoulis 1984, p. 147).

In order to explicitly find the MOMENTS of the distribution using the MOMENT-GENERATING FUNCTION, let

$$y \equiv \frac{(1 - \theta t)x}{\theta} \tag{7}$$

$$dy = \frac{1 - \theta t}{\theta}\ dx, \tag{8}$$

so

$$\begin{aligned} M(t) &= \int_0^\infty \left(\frac{\theta y}{1 - \theta t} \right)^{\alpha - 1} \frac{e^{-y}}{\Gamma(\alpha)\theta^\alpha} \frac{\theta\ dy}{1 - \theta t} \\ &= \frac{1}{(1 - \theta t)^\alpha \Gamma(\alpha)} \int_0^\infty y^{\alpha-1} e^{-y}\ dy \end{aligned}$$

$$= \frac{1}{(1-\theta t)^{\alpha}}, \quad (9)$$

giving the logarithmic MOMENT-GENERATING FUNCTION as

$$R(t) \equiv \ln M(t) = -\alpha \ln(1-\theta t) \quad (10)$$

$$R'(t) = \frac{\alpha\theta}{1-\theta t} \quad (11)$$

$$R''(t) = \frac{\alpha\theta^2}{(1-\theta t)^2}. \quad (12)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are then

$$\mu = R'(0) = \alpha\theta \quad (13)$$

$$\sigma^2 = R''(0)\alpha\theta^2 \quad (14)$$

$$\gamma_1 = \frac{2}{\sqrt{\alpha}} \quad (15)$$

$$\gamma_2 = \frac{6}{\alpha}. \quad (16)$$

The gamma distribution is closely related to other statistical distributions. If $X_1, X_2, ..., X_n$ are independent random variates with a gamma distribution having parameters $(\alpha_1, \theta), (\alpha_2, \theta), ..., (\alpha_n, \theta)$, then $\Sigma_{i=1}^{n} X_i$ is distributed as gamma with parameters

$$\alpha = \sum_{i=1}^{n} \alpha_i \quad (17)$$

$$\theta = \theta. \quad (18)$$

Also, if X_1 and X_2 are independent random variates with a gamma distribution having parameters (α_1, θ) and (α_2, θ), then $X_1/(X_1+X_2)$ is a BETA DISTRIBUTION variate with parameters (α_1, α_2). Both can be derived as follows.

$$P(x, y) = \frac{1}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{x_1+x_2} x_1^{\alpha_1-1} x_2^{\alpha_2-1}. \quad (19)$$

Let

$$u = x_1 + x_2 \qquad x_1 = uv \quad (20)$$

$$v = \frac{x_1}{x_1+x_2} \qquad x_2 = u(1-v), \quad (21)$$

then the JACOBIAN is

$$J\left(\frac{x_1, x_2}{u, v}\right) = \begin{vmatrix} v & u \\ 1-v & -u \end{vmatrix} = -u, \quad (22)$$

so

$$g(u, v)\,du\,dv = f(x, y)\,dx\,dy = f(x, y)u\,du\,dv. \quad (23)$$

$$g(u, v) = \frac{u}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{-u}(uv)^{\alpha_1-1}u^{\alpha_2-1}(1-v)^{\alpha_2-1}$$

$$= \frac{1}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{-u}u^{\alpha_1+\alpha_2-1}v^{\alpha_1-1}(1-v)^{\alpha_2-1}. \quad (24)$$

The sum $X_1 + X_2$ therefore has the distribution

$$f(u) = f(x_1+x_2) = \int_0^1 g(u, v)\,dv = \frac{e^{-u}u^{\alpha_1+\alpha_2-1}}{\Gamma(\alpha_1+\alpha_2)}, \quad (25)$$

which is a gamma distribution, and the ratio $X_1/(X_1+X_2)$ has the distribution

$$h(v) = h\left(\frac{x_1}{x_1+x_2}\right) = \int_0^\infty g(u, v)\,du$$

$$= \frac{v^{\alpha_1-1}(1-v)^{\alpha_2-1}}{B(\alpha_1, \alpha_2)}, \quad (26)$$

where B is the BETA FUNCTION, which is a BETA DISTRIBUTION.

If X and Y are gamma variates with parameters α_1 and α_2, the X/Y is a variate with a BETA PRIME DISTRIBUTION with parameters α_1 and α_2. Let

$$u = x + y \qquad v = \frac{x}{y}, \quad (27)$$

then the JACOBIAN is

$$J\left(\frac{u, v}{x, y}\right) = \begin{vmatrix} 1 & 1 \\ \frac{1}{y} & -\frac{x}{y^2} \end{vmatrix} = -\frac{x+y}{y^2} = -\frac{(1+v)^2}{u}, \quad (28)$$

so

$$dx\,dy = \frac{u}{(1+v)^2}\,du\,dv \quad (29)$$

$$g(u, v) = \frac{1}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{-u}\left(\frac{uv}{1+v}\right)^{\alpha_1-1}\left(\frac{u}{1+v}\right)^{\alpha_2-1} \times \frac{u}{(1+v)^2}$$

$$= \frac{1}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{-u}u^{\alpha_1+\alpha_2-1}\,v^{\alpha_2-1}(1+v)^{-\alpha_1-\alpha_2}. \quad (30)$$

The ratio X/Y therefore has the distribution

$$h(v) = \int_0^\infty (g(u, v)\,du = \frac{v^{\alpha_1-1}(1+v)^{-\alpha_1-\alpha_2}}{B(\alpha_1, \alpha_2)}, \quad (31)$$

which is a BETA PRIME DISTRIBUTION with parameters (α_1, α_2).

The "standard form" of the gamma distribution is given by letting $y \equiv x/\theta$, so $dy = dx/\theta$ and

$$P(y)\,dy = \frac{x^{\alpha-1}e^{-x/\theta}}{\Gamma(\alpha)\theta^{\alpha}}\,dx = \frac{(\theta y)\alpha^{-1}e^{-y}}{\Gamma(\alpha)\theta^{\alpha}}(\theta\,dy)$$

$$= \frac{y^{\alpha-1}e^{-y}}{\Gamma(\alpha)}\, dy, \tag{32}$$

so the MOMENTS about 0 are

$$v_r = \frac{1}{\Gamma(\alpha)} \int_0^\infty e^{-x} x^{\alpha-1+r}\, dx = \frac{\Gamma(\alpha + r)}{\Gamma(\alpha)} = (\alpha)_r, \tag{33}$$

where $(\alpha)_r$ is the POCHHAMMER SYMBOL. The MOMENTS about $\mu = \mu_1$ are then

$$\mu_1 = \alpha \tag{34}$$

$$\mu_2 = \alpha \tag{35}$$

$$\mu_3 = 2\alpha \tag{36}$$

$$\mu_4 = 3\alpha^2 + 6\alpha. \tag{37}$$

The MOMENT-GENERATING FUNCTION is

$$M(t) = \frac{1}{(1-t)^\alpha}, \tag{38}$$

and the CUMULANT-GENERATING FUNCTION is

$$K(t) = \alpha \ln(1-t) = \alpha(t + \tfrac{1}{2} t^2 + \tfrac{1}{3} t^3 + \ldots), \tag{39}$$

so the CUMULANTS are

$$\kappa_r = \alpha\Gamma(r). \tag{40}$$

If x is a NORMAL variate with MEAN μ and STANDARD DEVIATION σ, then

$$y \equiv \frac{(x-\mu)^2}{2\sigma^2} \tag{41}$$

is a standard gamma variate with parameter $\alpha = 1/2$.

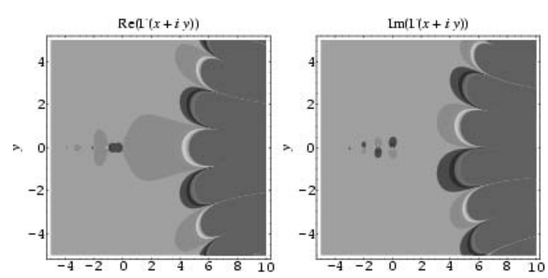
Gamma Function

The complete gamma function $\Gamma(n)$ is defined to be an extension of the FACTORIAL to COMPLEX and REAL NUMBER arguments. It is related to the FACTORIAL by $\Gamma(n) = (n = 1)!$. It is ANALYTIC everywhere except at $z = 0, -1, -2, \ldots$, and the residue at $z = -k$ is

$$\operatorname*{Res}_{z=-k} \Gamma(z) = \frac{(-1)^k}{k!}. \tag{1}$$

There are no points z at which $\Gamma(z) = 0$. The gamma function is implemented in *Mathematica* as `Gamma[z]`.



The gamma function can be defined as a DEFINITE INTEGRAL for $\Re[z] > 0$ (Euler's integral form)

$$\Gamma(z) \equiv \int_0^\infty t^{z-1} e^{-t}\, dt \tag{2}$$

$$= 2\int_0^\infty e^{-t^2} t^{2z-1}\, dt, \tag{3}$$

or

$$\Gamma(z) \equiv \int_0^1 \left[\ln\left(\frac{1}{t}\right)\right]^{z-1} dt. \tag{4}$$

Plots of the real and imaginary parts of $\Gamma(z)$ in the complex plane are illustrated above.

INTEGRATING (2) by parts for a REAL argument, it can be seen that

$$\Gamma(x)=\int_0^\infty t^{x-1}e^{-t}\,dt$$
$$=[-t^{x-1}e^{-t}]_0^\infty+\int_0^\infty (x-1)t^{x-2}e^{-t}\,dt$$
$$=(x-1)\int_0^\infty t^{x-2}e^{-t}\,dt=(x-1)\Gamma(x-1). \quad (5)$$

If x is an INTEGER $n=1, 2, 3, \ldots$ then

$$\Gamma(n)=(n-1)\Gamma(n-1)=(n-1)(n-2)\Gamma(n-2)$$
$$=(n-1)(n-2)\cdots 1=(n-1)!, \quad (6)$$

so the gamma function reduces to the FACTORIAL for a POSITIVE INTEGER argument.

The second of BINET'S LOG GAMMA FORMULAS is

$$\ln\Gamma(a)=(a-\tfrac{1}{2})\ln a-a+\tfrac{1}{2}\ln(2\pi)$$
$$+2\int_0^\infty \frac{\tan(\frac{z}{a})}{e^{2\pi z}-1}\,dz \quad (7)$$

for $\Re[a]>0$ (Whittaker and Watson 1990, p. 251). Another formula for $\ln\Gamma(z)$ is given by MALMSTÉN'S FORMULA, and $\ln\Gamma(z)$ is implemented in *Mathematica* as `LogGamma[z]`. The gamma function can also be defined by an INFINITE PRODUCT form (Weierstrass Form)

$$\Gamma(z)\equiv\left[ze^{\gamma z}\prod_{r=1}^{\infty}\left(1+\frac{z}{r}\right)e^{-z/r}\right]^{-1}, \quad (8)$$

where γ is the EULER-MASCHERONI CONSTANT (Krantz 1999, p. 157). This can be written

$$\Gamma(z)=\frac{1}{z}\exp\left[\sum_{k=1}^{\infty}\frac{(-1)^k s_k}{k}z^k\right], \quad (9)$$

where

$$s_1\equiv\gamma \quad (10)$$
$$s_k\equiv\zeta(k) \quad (11)$$

for $k\geq 2$, where $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Finch). Taking the logarithm of both sides of (8),

$$-\ln[\Gamma(z)]=\ln z+\gamma z+\sum_{n=1}^{\infty}\left[\ln\left(1+\frac{z}{n}\right)-\frac{z}{n}\right]. \quad (12)$$

Differentiating,

$$-\frac{\Gamma'(z)}{\Gamma(z)}=\frac{1}{z}+\gamma+\sum_{n=1}^{\infty}\left(\frac{\frac{1}{n}}{1+\frac{z}{n}}-\frac{1}{n}\right)$$
$$=\frac{1}{z}+\gamma+\sum_{n=1}^{\infty}\left(\frac{1}{n+z}-\frac{1}{n}\right) \quad (13)$$

$$\Gamma'(z)=-\Gamma(z)\left[\frac{1}{z}+\gamma+\sum_{n=1}^{\infty}\left(\frac{1}{n+z}-\frac{1}{n}\right)\right] \quad (14)$$

$$\equiv\Gamma(z)\Psi(z)=\Gamma(z)\psi_0(z) \quad (15)$$

$$\Gamma'(1)=-\Gamma(1)$$
$$-\left\{1+\gamma+\left[(\tfrac{1}{2}-1)+(\tfrac{1}{3}-\tfrac{1}{2})+\ldots+\left(\frac{1}{n+1}-\frac{1}{n}\right)+\ldots\right]\right\}$$
$$=-(1+\gamma-1)=-\gamma \quad (16)$$

$$\Gamma'(n)=-\Gamma(n)$$
$$\times\left\{\frac{1}{n}+\gamma+\left[\left(\frac{1}{1+n}-1\right)+\left(\frac{1}{2+n}-\frac{1}{2}\right)\right.\right.$$
$$\left.\left.+\left(\frac{1}{3+n}-\frac{1}{3}\right)+\ldots\right]\right\}$$
$$=-(n-1)!\left(\frac{1}{n}+\gamma-\sum_{k=1}^{n}\frac{1}{k}\right), \quad (17)$$

where $\Psi(z)$ is the DIGAMMA FUNCTION and $\psi_0(z)$ is the POLYGAMMA FUNCTION. nth derivatives are given in terms of the POLYGAMMA FUNCTIONS ψ_n, ψ_{n-1}, ..., ψ_0.

The minimum value x_0 of $\Gamma(x)$ for REAL POSITIVE $x=x_0$ is achieved when

$$\Gamma'(x_0)=\Gamma(x_0)\psi_0(x_0)=0 \quad (18)$$
$$\psi_0(x_0)=0, \quad (19)$$

This can be solved numerically to give $x_0=1.46163\ldots$ (Sloane's A030169; Wrench 1968), which has CONTINUED FRACTION [1, 2, 6, 63, 135, 1, 1, 1, 1, 4, 1, 38, ...] (Sloane's A030170). At x_0, $\Gamma(x_0)$ achieves the value 0.8856031944... (Sloane's A030171), which has CONTINUED FRACTION [0, 1, 7, 1, 2, 1, 6, 1, 1, ...] (Sloane's A030172).

The Euler limit form is

$$\frac{1}{\Gamma(z)}=z\left[\lim_{m\to\infty}e^{(1+1/2+\ldots+1/m-\ln m)z}\right]$$
$$\times\left[\lim_{m\to\infty}\prod_{n=1}^{m}\left\{\left(1+\frac{z}{n}\right)e^{-z/n}\right\}\right]$$
$$=\frac{1}{z}\prod_{n=1}^{\infty}\left[\left(1+\frac{1}{n}\right)^z\left(1+\frac{z}{n}\right)^{-1}\right], \quad (20)$$

so

$$\Gamma(z)\equiv\lim_{n\to\infty}\frac{1\cdot 2\cdot 3\cdots n}{z(z+1)(z+2)\cdots(z+n)}n^z \quad (21)$$

(Krantz 1999, p. 156). One over the gamma function is also given by

$$\frac{1}{\Gamma(z)} = z \exp\left[\gamma z - \sum_{k=2}^{\infty} \frac{(-1)^k \zeta(k) z^k}{k}\right], \tag{22}$$

where γ is the EULER-MASCHERONI CONSTANT and $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Wrench 1968). An ASYMPTOTIC SERIES for $1/\Gamma(z)$ is given by

$$\frac{1}{\Gamma(z)} \sim z + \gamma z^2 + \tfrac{1}{12}(6\gamma^2 - \pi^2)z^3 + \tfrac{1}{12}[2\gamma^3 - \gamma\pi^2 + 4\zeta(3)]z^4 + \ldots. \tag{23}$$

Writing

$$\frac{1}{\Gamma(z)} = \sum_{k=1}^{\infty} a_k z^k, \tag{24}$$

the a_k satisfy

$$a_n = na_1a_n - a_2a_{n-1} + \sum_{k=2}^{n}(-1)^k \zeta(k) a_{n-k} \tag{25}$$

(Bourget 1883, Isaacson and Salzer 1942, Wrench 1968). Wrench (1968) numerically computed the coefficients for the series expansion about 0 of

$$\frac{1}{z(1+z)\Gamma(z)} = 1 + (\gamma - 1)z + \left[1 + \tfrac{1}{2}(\gamma - 2)\gamma - \tfrac{1}{12}\pi^2\right]z^2 + \ldots. \tag{26}$$

The LANCZOS APPROXIMATION for $z > 0$ is

$$\Gamma(z+1) = (z + \gamma + \tfrac{1}{2})^{z+1/2} e^{z+\gamma+1/2} \sqrt{2\pi} \times \left[c_0 + \frac{c_1}{z+1} + \frac{c_2}{z+2} + \ldots + \frac{c_n}{z+n} + \varepsilon\right], \tag{27}$$

where γ is the EULER-MASCHERONI CONSTANT.

The gamma function satisfies the FUNCTIONAL EQUATIONS

$$\Gamma(1+z) = z\Gamma(z) \tag{28}$$

$$\Gamma(1-z) = -z\Gamma(-z). \tag{29}$$

Additional identities are

$$\Gamma(x)\Gamma(-x) = -\frac{\pi}{x \sin(\pi x)} \tag{30}$$

$$\Gamma(x)\Gamma(1-x) = \frac{\pi}{\sin(\pi x)} \tag{31}$$

$$\ln[\Gamma(x+iy+1)] = \ln(x^2+y^2) + i \tan^{-1}\left(\frac{y}{x}\right) + \ln[\Gamma(x+iy)] \tag{32}$$

$$|(ix)!|^2 = \frac{\pi x}{\sinh(\pi x)} \tag{33}$$

$$|(n+ix)!| = \sqrt{\frac{\pi x}{\sinh(\pi x)}} \prod_{s=1}^{n} \sqrt{s^2 + x^2}. \tag{34}$$

For integer $n = 1, 2, \ldots$, the first few values of $\Gamma(n)$ are 1, 1, 2, 6, 24, 120, 720, 5040, 40320, 362880, ... (Sloane's A000142). For half integer arguments, $\Gamma(n/2)$ has the special form

$$\Gamma\left(\tfrac{1}{2}n\right) = \frac{(n-2)!!\sqrt{\pi}}{2^{(n-1)/2}}, \tag{35}$$

where $n!!$ is a DOUBLE FACTORIAL. The first few values for $n = 1, 3, 5, \ldots$, are therefore

$$\Gamma(\tfrac{1}{2}) = \sqrt{\pi} \tag{36}$$

$$\Gamma(\tfrac{3}{2}) = \tfrac{1}{2}\sqrt{\pi} \tag{37}$$

$$\Gamma(\tfrac{5}{2}) = \tfrac{3}{4}\sqrt{\pi}, \tag{38}$$

$15\sqrt{\pi}/8$, $105\sqrt{\pi}/16$, ... (Sloane's A001147 and A000079; Wells 1986, p. 40). In general, for n a POSITIVE INTEGER $n = 1, 2, \ldots$

$$\Gamma\left(\tfrac{1}{2}+n\right) = \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2^n}\sqrt{\pi} = \frac{(2n-1)!!}{2^n}\sqrt{\pi} \tag{39}$$

$$\Gamma(\tfrac{1}{2}-n) = \frac{(-1)^n 2^n}{1 \cdot 3 \cdot 5 \cdots (2n-1)}\sqrt{\pi} = \frac{(-1)^n 2^n}{(2n-1)!!}\sqrt{\pi}. \tag{40}$$

For $\Re[x] = -\tfrac{1}{2}$,

$$|(-\tfrac{1}{2}+iy)!|^2 = \frac{\pi}{\cosh(\pi y)}. \tag{41}$$

Gamma functions of argument $2z$ can be expressed using the LEGENDRE DUPLICATION FORMULA

$$\Gamma(2z) = (2\pi)^{-1/2} 2^{2z-1/2} \Gamma(z)\Gamma(z+\tfrac{1}{2}). \tag{42}$$

Gamma functions of argument $3z$ can be expressed using a triplication FORMULA

$$\Gamma(3z) = (2\pi)^{-1} 3^{3z-1/2} \Gamma(z)\Gamma(z+\tfrac{1}{3})\Gamma(z+\tfrac{2}{3}). \tag{43}$$

The general result is the GAUSS MULTIPLICATION FORMULA

$$\Gamma(z)\Gamma(z+\tfrac{1}{n})\cdots\Gamma(z+\tfrac{n-1}{n}) = (2\pi)^{(n-1)/2} n^{1/2-nz}\Gamma(nz). \tag{44}$$

The gamma function is also related to the RIEMANN ZETA FUNCTION $\zeta(z)$ by

$$\Gamma\left(\frac{s}{2}\right)\pi^{-s/2}\zeta(s) = \Gamma\left(\frac{1-s}{2}\right)\pi^{-(1-s)/2}\zeta(1-s). \tag{45}$$

Borwein and Zucker (1992) give a variety of identities relating gamma functions to square roots and ELLIPTIC INTEGRAL SINGULAR VALUES k_n, i.e., MODULI k_n such that

$$\frac{K'(k_n)}{K(k_n)} = \sqrt{n}, \tag{46}$$

where $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND and $K'(k) = K(k)' = K(\sqrt{1-k^2})$ is the complementary integral. M. Trott has developed an algorithm for automatically generating hundreds of such identities.

$$\Gamma(\tfrac{1}{3}) = 2^{7/9} 3^{-1/12} \pi^{1/3} [K(k_3)]^{1/3} \tag{47}$$

$$\Gamma(\tfrac{1}{4}) = 2\pi^{1/4} [K(k_1)]^{1/2} \tag{48}$$

$$\Gamma(\tfrac{1}{6}) = 2^{-1/3} 3^{1/2} \pi^{-1/2} [\Gamma(\tfrac{1}{3})]^2 \tag{49}$$

$$\Gamma(\tfrac{1}{8})\Gamma(\tfrac{3}{8}) = (\sqrt{2}-1)^{1/2} 2^{13/4} \pi^{1/2} K(k_2) \tag{50}$$

$$\frac{\Gamma(\tfrac{1}{8})}{\Gamma(\tfrac{3}{8})} = 2(\sqrt{2}+1)^{1/2} \pi^{-1/4} [K(k_1)]^{1/2} \tag{51}$$

$$\Gamma(\tfrac{1}{12}) = 2^{-1/4} 3^{3/8} (\sqrt{3}+1)^{1/2} \pi^{-1/2} \Gamma(\tfrac{1}{4})\Gamma(\tfrac{1}{3}) \tag{52}$$

$$\Gamma(\tfrac{5}{12}) = 2^{1/4} 3^{-1/8} (\sqrt{3}-1)^{1/2} \pi^{1/2} \frac{\Gamma(\tfrac{1}{4})}{\Gamma(\tfrac{1}{3})} \tag{53}$$

$$\frac{\Gamma(\tfrac{1}{24})\Gamma(\tfrac{11}{24})}{\Gamma(\tfrac{5}{24})\Gamma(\tfrac{7}{24})} = \sqrt{3}\,\sqrt{2+\sqrt{3}} \tag{54}$$

$$\frac{\Gamma(\tfrac{1}{24})\Gamma(\tfrac{5}{24})}{\Gamma(\tfrac{7}{24})\Gamma(\tfrac{11}{24})} = 4 \cdot 3^{1/4} (\sqrt{3}+\sqrt{2}) \pi^{-1/2} K(k_1) \tag{55}$$

$$\frac{\Gamma(\tfrac{1}{24})\Gamma(\tfrac{7}{24})}{\Gamma(\tfrac{5}{24})\Gamma(\tfrac{11}{24})} = 2^{25/18} 3^{1/3} (\sqrt{2}+1) \pi^{-1/3} [K(k_3)]^{2/3} \tag{56}$$

$$\Gamma(\tfrac{1}{24})\Gamma(\tfrac{5}{24})\Gamma(\tfrac{7}{24})\Gamma(\tfrac{11}{24}) = 384(\sqrt{2}+1)(\sqrt{3}-\sqrt{2})(2-\sqrt{3})\pi[K(k_6)]^2 \tag{57}$$

$$\Gamma(\tfrac{1}{10}) = 2^{-7/10} 5^{1/4} (\sqrt{5}+1)^{1/2} \pi^{-1/2} \Gamma(\tfrac{1}{5})\Gamma(\tfrac{2}{5}) \tag{58}$$

$$\Gamma(\tfrac{3}{10}) = 2^{-3/5} (\sqrt{5}-1) \pi^{1/2} \frac{\Gamma(\tfrac{1}{5})}{\Gamma(\tfrac{2}{5})} \tag{59}$$

$$\frac{\Gamma(\tfrac{1}{15})\Gamma(\tfrac{4}{15})\Gamma(\tfrac{7}{15})}{\Gamma(\tfrac{2}{15})} = 2 \cdot 3^{1/2} 5^{1/6} \sin(\tfrac{2}{15}\pi)[\Gamma(\tfrac{1}{3})]^2 \tag{60}$$

$$\frac{\Gamma(\tfrac{1}{15})\Gamma(\tfrac{2}{15})\Gamma(\tfrac{7}{15})}{\Gamma(\tfrac{4}{15})} = 2^2 \cdot 3^{2/5} \sin(\tfrac{1}{5}\pi)\sin(\tfrac{4}{15}\pi)[\Gamma(\tfrac{1}{5})]^2 \tag{61}$$

$$\frac{\Gamma(\tfrac{2}{15})\Gamma(\tfrac{4}{15})\Gamma(\tfrac{7}{15})}{\Gamma(\tfrac{1}{15})} = \frac{2^{-3/2} 3^{-1/5} 5^{1/4} (\sqrt{5}-1)^{1/2} [\Gamma(\tfrac{2}{5})]^2}{\sin(\tfrac{4}{15}\pi)} \tag{62}$$

$$\frac{\Gamma(\tfrac{1}{15})\Gamma(\tfrac{2}{15})\Gamma(\tfrac{4}{15})}{\Gamma(\tfrac{7}{15})} = 60(\sqrt{5}-1)\sin(\tfrac{7}{15}\pi)[K(k_{15})]^2 \tag{63}$$

$$\frac{\Gamma(\tfrac{1}{20})\Gamma(\tfrac{9}{20})}{\Gamma(\tfrac{3}{20})\Gamma(\tfrac{7}{20})} = 2^{-1} 5^{1/4} (\sqrt{5}+1) \tag{64}$$

$$\frac{\Gamma(\tfrac{1}{20})\Gamma(\tfrac{3}{20})}{\Gamma(\tfrac{7}{20})\Gamma(\tfrac{9}{20})} = 2^{4/5} (10-2\sqrt{5})^{1/2} \pi^{-1} \sin(\tfrac{7}{20}\pi)\sin(\tfrac{9}{20}\pi) \times [\Gamma(\tfrac{1}{5})]^2 \tag{65}$$

$$\frac{\Gamma(\tfrac{1}{20})\Gamma(\tfrac{7}{20})}{\Gamma(\tfrac{3}{20})\Gamma(\tfrac{9}{20})} = 2^{3/5} (10+2\sqrt{5})^{1/2} \pi^{-1} \sin(\tfrac{3}{20}\pi)\sin(\tfrac{9}{20}\pi) \times [\Gamma(\tfrac{2}{5})]^2 \tag{66}$$

$$\Gamma(\tfrac{1}{20})\Gamma(\tfrac{3}{20})\Gamma(\tfrac{7}{20})\Gamma(\tfrac{9}{20}) = 160(\sqrt{5}-2)^{1/2}\pi[K(k_5)]^2. \tag{67}$$

Several of these are also given in Campbell (1966, p. 31).

A few curious identities include

$$\prod_{n=1}^{8} \Gamma\left(\tfrac{1}{3}n\right) = \frac{640}{3^6}\left(\frac{\pi}{\sqrt{3}}\right)^3 \tag{68}$$

$$\frac{[\Gamma\left(\tfrac{1}{4}\right)]^4}{16\pi^2} = \frac{3^2}{3^2-1}\,\frac{5^2-1}{5^2}\,\frac{7^2}{7^2-1}\cdots \tag{69}$$

$$\frac{\Gamma'(1)}{\Gamma(1)} - \frac{\Gamma'\left(\tfrac{1}{2}\right)}{\Gamma\left(\tfrac{1}{2}\right)} = 2\ln 2 \tag{70}$$

(Magnus and Oberhettinger 1949, p. 1). Ramanujan also gave a number of fascinating identities:

$$\frac{\Gamma^2(n+1)}{\Gamma(n+xi+1)\Gamma(n-xi+1)} = \prod_{k=1}^{\infty}\left[1+\frac{x^2}{(n+k)^2}\right] \tag{71}$$

$$\phi(m,n)\phi(n,m) = \frac{\Gamma^3(m+1)\Gamma^3(n+1)}{\Gamma(2m+n+1)\Gamma(2n+m+1)} \times \frac{\cosh\left[\pi(m+n)\sqrt{3}\right] - \cos[\pi(m-n)]}{2\pi^2(m^2+mn+n^2)}, \tag{72}$$

where

$$\phi(m,n) \equiv \prod_{k=1}^{\infty}\left[1+\left(\frac{m+n}{k+m}\right)^3\right], \tag{73}$$

$$\prod_{k=1}^{\infty}\left[1+\left(\frac{n}{k}\right)^3\right]\prod_{k=1}^{\infty}\left[1+3\left(\frac{n}{n+2k}\right)^2\right]$$

$$= \frac{\Gamma\left(\frac{1}{2}n\right)}{\Gamma\left[\frac{1}{2}(n+1)\right]} \frac{\cosh(\pi n\sqrt{3}) - \cos(\pi n)}{2^{n+2}\pi^{3/2}n} \quad (74)$$

(Berndt 1994).

Ramanujan gave the infinite sums

$$1+9\left(\tfrac{1}{4}\right)^4+17\left(\frac{1\cdot 5}{4\cdot 8}\right)^4+25\left(\frac{1\cdot 5\cdot 9}{4\cdot 8\cdot 12}\right)^4+\ldots$$

$$=\sum_{k=0}^{\infty}(8k+1)\left[\frac{\Gamma\left(k+\frac{1}{4}\right)}{k!\,\Gamma\left(\frac{1}{4}\right)}\right]^4=\frac{2^{3/2}}{\sqrt{\pi}\left[\Gamma\left(\frac{3}{4}\right)\right]^2} \quad (75)$$

and

$$1-5\left(\tfrac{1}{2}\right)^5+9\left(\frac{1\cdot 3}{2\cdot 4}\right)^5-13\left(\frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\right)^5+\ldots$$

$$=\sum_{k=0}^{\infty}(-1)^k(4k+1)\left[\frac{(2k-1)!!}{(2k)!!}\right]^5=\frac{2}{\left[\Gamma\left(\frac{3}{4}\right)\right]^4}. \quad (76)$$

(Hardy 1923; Hardy 1924; Whipple 1926; Watson 1931; Bailey 1935; Hardy 1999, p. 7).

The following ASYMPTOTIC SERIES is occasionally useful in probability theory (e.g., the 1-D RANDOM WALK):

$$\frac{\Gamma\left(J+\frac{1}{2}\right)}{\Gamma(J)}$$

$$=\sqrt{J}\left(1-\frac{1}{8J}+\frac{1}{128J^2}+\frac{5}{1024J^3}-\frac{21}{32768J^4}+\ldots\right) \quad (77)$$

(Graham *et al.* 1994). This series also gives a nice asymptotic generalization of STIRLING NUMBERS OF THE FIRST KIND to fractional values.

It has long been known that $\Gamma(\frac{1}{4})\pi^{-1/4}$ is TRANSCENDENTAL (Davis 1959), as is $\Gamma(\frac{1}{3})$ (Le Lionnais 1983), and Chudnovsky has apparently recently proved that $\Gamma(\frac{1}{4})$ is itself TRANSCENDENTAL.

The complete gamma function $\Gamma(x)$ can be generalized to the upper INCOMPLETE GAMMA FUNCTION $\Gamma(a, x)$ and lower INCOMPLETE GAMMA FUNCTION $\gamma(a, x)$.

Garsia-Haiman Conjecture

N! THEOREM

Garsia-Milne Involution Principle

Let $C = C^+ \cup C^-$ (where $C^+ \cap C^- = \phi$) be the DISJOINT UNION of two finite components C^+ and C^-. Let α and β be two involutions on C, each of whose fixed points lie in C^+. Let F_α (respectively, F_β) denote the fixed point set of α (respectively, β). Stipulate that $\alpha(C^+ - F_\alpha) \subset C^-$ and $\alpha(C^-) \subset C^+$, and similarly $\beta(C^+ - F_\beta) \subset C^-$ and $\beta(C^-) \subset C^+$ (i.e., outside the fixed point sets), both α and β map each component into the other. Then either a cycle of the PERMUTATION $\Delta = \alpha\beta$ contains no fixed points of either α or β, or it contains exactly one element of F_α and one of F_β.

Gauss Integral

Consider two closed oriented SPACE CURVES $f_1 : C_1 \to \mathbb{R}^3$ and $f_2 : C_2 \to \mathbb{R}^3$, where C_1 and C_2 are distinct CIRCLES, f_1 and f_2 are differentiable C^1 functions, and $f_1(C_1)$ and $f_2(C_3)$ are disjoint loci. Let $\mathrm{Lk}(f_1, f_2)$ be the LINKING NUMBER of the two curves, then the Gauss integral is

$$\mathrm{Lk}(f_1, f_2) = \frac{1}{4\pi}\int_{C_1 \times C_2} dS.$$

Gauss Map

The Gauss map is a function from an ORIENTABLE SURFACE M in EUCLIDEAN SPACE to a SPHERE. It associates to every point on the surface its oriented NORMAL VECTOR. For a COMPACT SURFACE M in 3-space, the Gauss map of M has DEGREE given by half the EULER CHARACTERISTIC of the surface

$$\int\int_M K\,dA = 2\pi\chi(M) - \sum \alpha_i - \int_{\partial T} \kappa_g\,ds,$$

where this formula holds only for ORIENTABLE SURFACES.

Gauss's Circle Problem

Count the number of LATTICE POINTS $N(r)$ inside the boundary of a CIRCLE of RADIUS r with center at the origin. The exact solution is given by the SUM

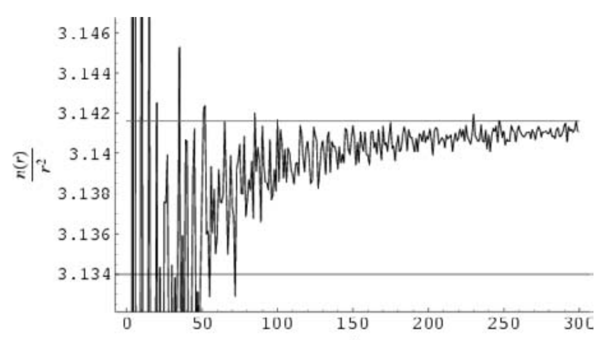
$$N(r) = 1 + 4\lfloor r\rfloor + 4\sum_{i=1}^{\lfloor r\rfloor}\left\lfloor\sqrt{r^2-i^2}\right\rfloor \quad (1)$$

$$= 1 + 4\sum_{i=1}^{r^2}(-1)^{i-1}\left\lfloor\frac{r^2}{2i-1}\right\rfloor \quad (2)$$

(Hilbert and Cohn-Vossen 1999, p. 39). The first few values for $r = 0, 1, \ldots$ are 1, 5, 13, 29, 49, 81, 113, 149, ... (Sloane's A000328).

The series for $N(r)$ is intimately connected with $r(n)$, the number of representations of n by two squares, since

$$N(r) = \sum_{n=0}^{r^2} r(n) \quad (3)$$



(Hardy 1999, p. 67). $N(r)$ is also closely connected with the LEIBNIZ SERIES since

$$\frac{1}{4}\left[\frac{N(r)}{r^2} - \frac{1}{r^2}\right] = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \ldots \pm \frac{1}{r}, \quad (4)$$

so taking the limit $r \to \infty$ gives

$$\tfrac{1}{4}\pi = 1 - \tfrac{1}{3} + \tfrac{1}{5} - \tfrac{1}{7} + \tfrac{1}{9} + \ldots \quad (5)$$

(Hilbert and Cohn-Vossen 19991, p. 39).

Gauss showed that

$$N(r) = \pi r^2 + E(r), \quad (6)$$

where

$$|E(r)| \le 2\sqrt{2}\pi r \quad (7)$$

(Hardy 1999, p. 67). Writing $|E(r)| \leq Cr^{\theta}$, the best bounds on θ are

$$1/2 < \theta \leq 46/73 \approx 0.630137$$

(Huxley 1990). The lower limit 1/2 was obtained independently by Hardy and Landau in 1915. The following table summarizes incremental improvements in the upper limit (Hardy 1999, p. 81).

θ	approx.	citation
46/73	0.63014	Huxley 1990
7/11	0.63636	
24/37	0.64864	Cheng 1963
34/53	0.64150	Vinogradov
37/56	0.66071	Littlewood and Walfisz 1924
2/3	0.66667	Sierpinski1906, van der Corput 1923

The problem has also been extended to CONICS, ellipsoids (Hardy 1915), and higher dimensions.

Gauss's Class Number Conjecture

In his monumental treatise *Disquisitiones Arithmeticae,* Gauss conjectured that the CLASS NUMBER $h(-d)$ of an IMAGINARY QUADRATIC FIELD with DISCRIMINANT $-d$ tends to infinity with d. A proof was finally given by Heilbronn (1934), and Siegel (1936) showed that for any $\epsilon > 0$, there exists a constant $c_\epsilon > 0$ such that

$$h(-d) > c_\epsilon d)^{1/2-\epsilon}$$

as $d \to \infty$. However, these results were not effective in actually determining the values for a given m of a complete list of fundamental discriminants $-d$ such that $h(-d) = m$, a problem known as GAUSS'S CLASS NUMBER PROBLEM.

Goldfeld (1976) showed that if there exists a "Weil curve" whose associated DIRICHLET L-SERIES has a zero of at least third order at $s = 1$, then for any $\epsilon > 0$, there exists an effectively computable constant c_ϵ such that

$$h(-d) > c_\epsilon (\ln d)^{1-\epsilon}.$$

Gross and Zaiger (1983) showed that certain curves must satisfy the condition of Goldfeld, and Goldfeld's proof was simplified by Oesterlé (1985).

Gauss's Class Number Problem

For a given m, determine a complete list of fundamental DISCRIMINANTS $-d$ such that the CLASS NUMBER is given by $h(-d) = m$. Heegner (1952) gave a solution for $m = 1$, but it was not completely accepted due to a number of apparent gaps. However, subse-

quent examination of Heegner's proof showed it to be "essentially" correct (Conway and Guy 1996). Conway and Guy (1996) therefore call the nine values of $n(-d)$ having $h(-d)=1$ where $-d$ is the DISCRIMINANT corresponding to an QUADRATIC FIELD $a+b\sqrt{-n}$ ($n=-1$, -2, -3, -7, -11, -19, -43, -67, and -163; Sloane's A003173) the HEEGNER NUMBERS. The HEEGNER NUMBERS have a number of fascinating properties.

Stark (1967) and Baker (1966) gave independent proofs of the fact that only nine such numbers exist; both proofs were accepted. Baker (1971) and Stark (1975) subsequently and independently solved the generalized class number problem completely for $m=2$. Oesterlé (1985) solved the case $m=3$, and Arno (1992) solved the case $m=4$. Wagner (1996) solve the cases $n=5$, 6, and 7. Arno *et al.* (1993) solved the problem for ODD m satisfying $5 \leq m \leq 23$. In his thesis, M. Watkins has solved the problem for all $m \leq 16$.

Gauss's Constant

The RECIPROCAL of the ARITHMETIC-GEOMETRIC MEAN of 1 and $\sqrt{2}$,

$$G \equiv \frac{1}{M(1, \sqrt{2})} \tag{1}$$

$$= \frac{2}{\pi}\int_0^1 \frac{1}{\sqrt{1-x^4}}\,dx \tag{2}$$

$$= \frac{2}{\pi}\int_0^{\pi/2} \frac{d\theta}{\sqrt{1+\sin^2\theta}} \tag{3}$$

$$= \frac{\sqrt{2}}{\pi} K\left(\frac{1}{\sqrt{2}}\right) \tag{4}$$

$$= \frac{1}{(2\pi)^{3/2}}[\Gamma(\tfrac{1}{4})]^2 \tag{5}$$

$$= 0.83462684167\ldots \tag{6}$$

(Sloane's A014549), where $K(k)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND and $\Gamma(z)$ is the GAMMA FUNCTION. Gauss's constant has CONTINUED FRACTION [0, 1, 5, 21, 3, 4, 14, 1, 1, 1, 1, 1, 3, 1, 15, ...] (Sloane's A053002).

The inverse of Gauss's constant is given by

$$\frac{1}{G} = 1.198140234735592207439\ldots \tag{7}$$

(Sloane's A053004), and has [1, 5, 21, 3, 4, 14, 1, 1, 1, 1, 1, 3, 1, 15, 1, ...] (Sloane's A053003).

Gauss's Criterion

Let p be an ODD PRIME and b a POSITIVE INTEGER not divisible by p. Then for each POSITIVE ODD INTEGER $2k-1<p$, let r_k be

$$r_k \equiv (2k-1)b \pmod{p}$$

with $0 < r_k < p$, and let t be the number of EVEN r_ks. Then

$$(b/p) = (-1)^t,$$

where (b/p) is the LEGENDRE SYMBOL.

References

Shanks, D. "Gauss's Criterion." §1.17 in *Solved and Unsolved Problems in Number Theory, 4th ed.* New York: Chelsea, pp. 38–0, 1993.

Gauss's Cyclotomic Formula

Let $p > 3$ be a PRIME NUMBER, then

$$4\frac{x^p - y^p}{x-y} = R^2(x, y) - (-1)^{(p-1)/2} p S^2(x, y),$$

where $R(x, y)$ and $S(x, y)$ are HOMOGENEOUS POLYNOMIALS in x and y with integer COEFFICIENTS. Gauss (1965, p. 467) gives the coefficients of R and S up to $p = 23$.

Kraitchik (1924) generalized Gauss's formula to odd SQUAREFREE integers $n > 3$. Then Gauss's formula can be written in the slightly simpler form

$$4\Phi_n(z) = A_n^2(z) - (-1)^{(n-1)/2} n z^2 B_n^2(z),$$

where $A_n(z)$ and $B_n(z)$ have integer coefficients and are of degree $\phi(n)/2$ and $\phi(n)/2 - 2$, respectively, with $\phi(n)$ the TOTIENT FUNCTION and $\Phi_n(z)$ a CYCLOTOMIC POLYNOMIAL. In addition, $A_n(z)$ is symmetric if n is EVEN; otherwise it is antisymmetric. $B_n(z)$ is symmetric in most cases, but it antisymmetric if n is OF THE FORM $4k+3$ (Riesel 1994, p. 436). The following table gives the first few $A_n(z)$ and $B_n(z)$s (Riesel 1994, pp. 436–42).

n	$A_n(z)$	$B_n(z)$
5	$2z^2 + z + 2$	1
7	$2z^3 + z^2 - z - 2$	$z + 1$
11	$2z^5 + z^4 - 2z^3 + 2z^2 - z - 2$	$z^3 + 1$

Gauss's Digamma Theorem

At rational arguments p/q, the DIGAMMA FUNCTION $\psi_0(p/q)$ is given by

$$\psi_0\left(\frac{p}{q}\right) = -\gamma - \ln(2q) - \tfrac{1}{2}\pi \cot\left(\frac{p}{q}\pi\right) + 2\sum_{k=1}^{\lceil q/2\rceil - 1} \cos\left(\frac{2\pi pk}{q}\right) \ln\left[\sin\left(\frac{\pi k}{q}\right)\right] \quad (1)$$

for $0 < p < q$ (Knuth 1997, p. 94). These give the special values

$$\psi_o(\tfrac{1}{2}) = -\gamma - 2\ln 2 \quad (2)$$

$$\psi_0(\tfrac{1}{3}) = \tfrac{1}{6}(-6\gamma - \pi\sqrt{3} - 9\ln 3) \quad (3)$$

$$\psi_0(\tfrac{2}{3}) = \tfrac{1}{6}(-6\gamma + \pi\sqrt{3} - 9\ln 3) \quad (4)$$

$$\psi_0(\tfrac{1}{4}) = \tfrac{1}{2}(-2\gamma - \pi - 6\ln 2) \quad (5)$$

$$\psi_0(\tfrac{3}{4}) = \tfrac{1}{2}(-2\gamma + \pi - 6\ln 2) \quad (6)$$

$$\psi_0(\tfrac{1}{6}) = -\gamma - \tfrac{1}{2}\sqrt{3}\pi - 2\ln 2 - \tfrac{3}{2}\ln 3) \quad (7)$$

$$\psi_0(\tfrac{5}{6}) = -\gamma + \tfrac{1}{2}\sqrt{3}\pi - 2\ln 2 - \tfrac{3}{2}\ln 3) \quad (8)$$

$$\psi_0(1) = -\gamma, \quad (9)$$

where γ is the EULER-MASCHERONI CONSTANT.

Gauss's Lemma

Let the multiples m, $2m$, ..., $[(p-1)/2]m$ of an INTEGER such that $p \nmid m$ be taken. If there are an EVEN NUMBER r of least POSITIVE RESIDUES mod p of these numbers $> p/2$, then m is a QUADRATIC RESIDUE of p. If r is ODD, m is a QUADRATIC NONRESIDUE. Gauss's lemma can therefore be stated as $(m|p) = (-1)^r$, where $(m|p)$ is the LEGENDRE SYMBOL. It was proved by Gauss as a step along the way to the QUADRATIC RECIPROCITY THEOREM (Nagell 1951).

Another result known as Gauss's lemma states that for any two integer a and b, suppose $d|ab$. Then if d is RELATIVELY PRIME to a, then d divides b (Séroul 2000, p. 10).

Gauss's Machin-Like Formula

The MACHIN-LIKE FORMULA

$$\tfrac{1}{4}\pi = 12\cot^{-1} 18 + 8\cot^{-1} 57 - 5\cot^{-1} 239.$$

Gauss's Mean-Value Theorem

Let $f(z)$ be an ANALYTIC FUNCTION in $|z-a| < R$. Then

$$f(z) = \frac{1}{2\pi}\int_0^{2\pi} f(z + re^{i\theta})\, d\theta$$

for $0 < r < R$.

Gauss's Polynomial Identity

For even h,

$$1 - \frac{1-x^h}{1-x} + \frac{(1-x^h)(1-x^{h-1})}{(1-x)(1-x^2)} - \frac{(1-x^h)(1-x^{h-1})(1-x^{h-2})}{(1-x)(1-x^2)(1-x^3)} + \ldots = (1-x)(1-x^3)(1-x^5)\cdots(1-x^{h-1}) \quad (1)$$

(Nagell 1951, p. 176). Writing out explicitly,

$$\sum_{n=0}^{h} \frac{(-1)^n \Pi_{k=0}^{n-1}(1-x^{h-k})}{\Pi_{k=1}^{n}} = \prod_{k=0}^{(h-1)/2} 1 - x^{2k+1}. \quad (2)$$

For example, for $h = 2$,

$$1 - \frac{1-x^2}{1-x} + \frac{(1-x)(1-x^2)}{(1-x)(1-x^2)} = 2 - \frac{1-x^2}{1-x} = 1 - x, \quad (3)$$

and for $h = 4$,

$$1 - \frac{1-x^4}{1-x} + \frac{(1-x^4)(1-x^3)}{(1-x)(1-x^2)} - \frac{(1-x^4)(1-x^3)(1-x^2)}{(1-x)(1-x^2)(1-x^3)} + \frac{(1-x)(1-x^2)(1-x^3)(1-x^4)}{(1-x)(1-x^2)(1-x^3)(1-x^4)} = 2 - \frac{2(1-x^4)}{1-x} + \frac{(1-x^3)(1-x^4)}{(1-x)(1-x^2)} = (1-x)(1-x^3). \quad (4)$$

Gauss's Polynomial Theorem

If an INTEGER POLYNOMIAL

$$f(x) = x^N + C_1 x^{N-1} + C_2 x^{N-2} + \ldots + C_N$$

is divisible into a product of two POLYNOMIALS $f = \psi\phi$

$$\psi = x^m + \alpha_1 x^{m-1} + \ldots + \alpha_m$$

$$\phi = x^n + \beta_1 x^{n-1} + \ldots + \beta_n,$$

then the COEFFICIENTS of these POLYNOMIALS are INTEGERS.

QUADRATIC RECIPROCITY THEOREM

Gauss's Test

If $u_n > 0$ and given $B(n)$ a bounded function of n as $n \to \infty$, express the ratio of successive terms as

$$\left|\frac{u_n}{u_{n+1}}\right| = 1 + \frac{h}{n} + \frac{B(n)}{n^r}$$

for $r > 1$. The SERIES converges for $h > 1$ and diverges for $h \leq 1$ (Courant and John 1999, p. 567).

Gauss's Theorem

DIVERGENCE THEOREM, GAUSS'S DIGAMMA THEOREM, GAUSS'S DOUBLE POINT THEOREM, GAUSS'S HYPERGEOMETRIC THEOREM, GAUSS'S THEOREMA EGREGIUM

Gauss's Theorema Egregium

Gauss's theorema egregium states that the GAUSSIAN CURVATURE of a surface embedded in 3-space may be understood intrinsically to that surface. "Residents" of the surface may observe the GAUSSIANCURVATURE of the surface without ever venturing into full 3-dimensional space; they can observe the curvature of the surface they live in without even knowing about the 3-dimensional space in which they are embedded.

In particular, GAUSSIAN CURVATURE can be measured by checking how closely the ARC LENGTH of small RADIUS CIRCLES correspond to what they should be in EUCLIDEAN SPACE, $2\pi r$. If the ARC LENGTH of CIRCLES tends to be smaller than what is expected in EUCLIDEAN SPACE, then the space is positively curved; if larger, negatively; if the same, 0 GAUSSIAN CURVATURE.

Gauss (effectively) expressed the theorema egregium by saying that the GAUSSIAN CURVATURE at a point is given by $-R(v, w)v, w$ where R is the RIEMANN TENSOR, and v and w are an orthonormal basis for the TANGENT SPACE.

Gauss's Transformation

If

$$(1+x\sin^2\alpha)\sin\beta = (1+x)\sin\alpha,$$

then

$$(1+x)\int_0^\alpha \frac{d\phi}{\sqrt{1-x^2\sin^2\phi}} = \int_0^\beta \frac{d\phi}{\sqrt{1-\frac{4x}{(1+x)^2}\sin^2\phi}}.$$

Gauss-Bolyai-Lobachevsky Space

A non-Euclidean space with constant NEGATIVE GAUSSIAN CURVATURE.

See also LOBACHEVSKY-BOLYAI-GAUSS GEOMETRY, NON-EUCLIDEAN GEOMETRY

Gauss-Bonnet Formula

The Gauss-Bonnet formula has several formulations. The simplest one expresses the total GAUSSIAN CURVATURE of an embedded triangle in terms of the total GEODESIC CURVATURE of the boundary and the JUMP ANGLES at the corners.

More specifically, if M is any 2-D RIEMANNIAN MANIFOLD (like a surface in 3-space) and if T is an embedded triangle, then the Gauss-Bonnet formula states that the integral over the whole triangle of the GAUSSIAN CURVATURE with respect to AREA is given by 2π minus the sum of the JUMP ANGLES minus the

integral of the GEODESIC CURVATURE over the whole of the boundary of the triangle (with respect to ARC LENGTH),

$$\iint_T K\,dA = 2\pi - \sum \alpha_i - \int_{\partial T} k_g\,ds, \qquad (1)$$

where K is the GAUSSIAN CURVATURE, dA is the AREA measure, the α_is are the JUMP ANGLES of ∂T, and k_g is the GEODESIC CURVATURE of ∂T, with ds the ARC LENGTH measure.

The next most common formulation of the Gauss-Bonnet formula is that for any compact, boundaryless 2-D RIEMANNIAN MANIFOLD, the integral of the GAUSSIAN CURVATURE over the entire MANIFOLD with respect to AREA is 2π times the EULER CHARACTERISTIC of the MANIFOLD,

$$\iint_M K\,dA = 2\pi\chi(M). \qquad (2)$$

This is somewhat surprising because the total GAUSSIAN CURVATURE is differential-geometric in character, but the EULER CHARACTERISTIC is topological in character and does not depend on differential geometry at all. So if you distort the surface and change the curvature at any location, regardless of how you do it, the same total curvature is maintained.

Another way of looking at the Gauss-Bonnet theorem for surfaces in 3-space is that the GAUSS MAP of the surface has DEGREE given by half the EULER CHARACTERISTIC of the surface

$$\iint_M K\,dA = 2\pi\chi(M) - \sum \alpha_i - \int_{\partial M} k_g\,ds, \qquad (3)$$

which works only for ORIENTABLE SURFACES where M is COMPACT. This makes the Gauss-Bonnet theorem a simple consequence of the POINCARE-HOPF INDEX THEOREM, which is a nice way of looking at things if you're a topologist, but not so nice for a differential geometer. This proof can be found in Guillemin and Pollack (1974). Millman and Parker (1977) give a standard differential-geometric proof of the Gauss-Bonnet theorem, and Singer and Thorpe (1996) give a GAUSS'S THEOREMA EGREGIUM-inspired proof which is entirely intrinsic, without any reference to the ambient EUCLIDEAN SPACE.

A general Gauss-Bonnet formula that takes into account both formulas can also be given. For any compact 2-D RIEMANNIAN MANIFOLD with corners, the integral of the GAUSSIAN CURVATURE over the 2-MANIFOLD with respect to AREA is 2π times the EULER CHARACTERISTIC of the MANIFOLD minus the sum of the JUMP ANGLES and the total GEODESIC CURVATURE of the boundary.

Gauss-Bonnet Theorem

GAUSS-BONNET FORMULA

Gaussian Approximation Algorithm

ARITHMETIC-GEOMETRIC MEAN

Gaussian Bivariate Distribution

The Gaussian bivariate distribution is given by

$$P(x_1,\ x_2) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} \exp\left[-\frac{z}{2(1-\rho^2)}\right], \qquad (1)$$

where

$$z \equiv \frac{(x_1-\mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1-\mu_1)(x_2-\mu_2)}{\sigma_1\sigma_2} + \frac{(x_2-\mu_2)^2}{\sigma_2^2}, \qquad (2)$$

and

$$\rho \equiv \operatorname{cor}(x_1,\ x_2) = \frac{\sigma_{12}}{\sigma_1\sigma_2} \qquad (3)$$

is the CORRELATION of x_1 and x_2 (Kenney and Keeping 1951, pp. 92 and 202–05; Whittaker and Robinson 1967, p. 329). The Gaussian bivariate distribution is implemented in *Mathematica* as `MultinormalDistribution[{`*mu1*, *mu2*`}, {{`*sigma11*, *sigma12*`}, {`*sigma12*, *sigma22*`}}, {`*x1*, *x2*`}]` in the *Mathematica* add-on package `Statistics'MultinormalDistribution'` (which can be loaded with the command `<<Statistics'`).

The MARGINAL PROBABILITIES are then

$$P(x_1) = \int_{-\infty}^{\infty} P(x_1,\ x_2)\,dx_2 = \frac{1}{\sigma_1\sqrt{2\pi}}\, e^{-(x_1-\mu_1)^2/(2\sigma_1^2)} \qquad (4)$$

and

$$P(x_2) = \int_{-\infty}^{\infty} P(x_1,\ x_2)\,dx_1 = \frac{1}{\sigma_2\sqrt{2\pi}} \exp\left[-\frac{(x_2-\mu_2)^2}{(2\sigma_2^2)}\right] \qquad (5)$$

(Kenney and Keeping 1951, p. 202).

Let z_1 and z_2 be two independent Gaussian variables with MEANS $\mu_i = 0$ and $\sigma_i^2 = 1$ for $i = 1, 2$. Then the variables a_1 and a_2 defined below are Gaussian bivariates with unit VARIANCE and CROSS-CORRELATION COEFFICIENT ρ :

$$a_1 = \sqrt{\frac{1+\rho}{2}}\, z_1 + \sqrt{\frac{1-\rho}{2}}\, z_2 \tag{6}$$

$$a_2 = \sqrt{\frac{1+\rho}{2}}\, z_1 - \sqrt{\frac{1-\rho}{2}}\, z_2. \tag{7}$$

To derive the Gaussian bivariate probability function, let X_1 and X_2 be normally and independently distributed variates with MEAN 0 and VARIANCE 1, then define

$$Y_1 \equiv \mu_1 + \sigma_{11}X_1 + \sigma_{12}X_2 \tag{8}$$

$$Y_2 \equiv \mu_2 + \sigma_{21}X_1 + \sigma_{22}X_2 \tag{9}$$

(Kenney and Keeping 1951, p. 92). The variates Y_1 and Y_2 are then themselves normally distributed with MEANS μ_1 and μ_2, VARIANCES

$$\sigma_1^2 \equiv \sigma_{11}^2 + \sigma_{12}^2 \tag{10}$$

$$\sigma_2^2 \equiv \sigma_{21}^2 + \sigma_{22}^2, \tag{11}$$

and COVARIANCE

$$V_{12} \equiv \sigma_{11}\sigma_{21} + \sigma_{12}\sigma_{22}. \tag{12}$$

The COVARIANCE matrix is defined by

$$V_{ij} = \begin{bmatrix} \sigma_1^2 & \rho\sigma_1\sigma_2 \\ \rho\sigma_1\sigma_2 & \sigma_2^2 \end{bmatrix}, \tag{13}$$

where

$$\rho \equiv \frac{V_{12}}{\sigma_1\sigma_2} = \frac{\sigma_{11}\sigma_{21} + \sigma_{12}\sigma_{22}}{\sigma_1\sigma_2}. \tag{14}$$

Now, the joint probability density function for x_1 and x_2 is

$$f(x_1, x_2)\, dx_1\, dx_2 = \frac{1}{2\pi} e^{-(x_1^2+x_2^2)/2}\, dx_1 dx_2, \tag{15}$$

but from (8) and (9), we have

$$\begin{bmatrix} y_1 - \mu_1 \\ y_2 - \mu_2 \end{bmatrix} = \begin{bmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}. \tag{16}$$

As long as

$$\begin{bmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{bmatrix} \neq 0, \tag{17}$$

this can be inverted to give

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{bmatrix}^{-1} \begin{bmatrix} y_1 - \mu_1 \\ y_2 - \mu_2 \end{bmatrix}$$
$$= \frac{1}{\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21}} \begin{bmatrix} \sigma_{22} & -\sigma_{12} \\ -\sigma_{21} & \sigma_{11} \end{bmatrix} \begin{bmatrix} y_1 - \mu_1 \\ y_2 - \mu_2 \end{bmatrix}. \tag{18}$$

Therefore,

$$x_1^2 + x_2^2 = \frac{[\sigma_{22}(y_1 - \mu_1) - \sigma_{12}(y_2 - \mu_2)]^2}{(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2} + \frac{[-\sigma_{21}(y_1 - \mu_1) - \sigma_{11}(y_2 - \mu_2)]^2}{(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2}, \tag{19}$$

and expanding the NUMERATOR of (19) gives

$$\sigma_{22}^2(y_1-\mu_1)^2 - 2\sigma_{12}\sigma_{22}(y_1-\mu_1)(y_2-\mu_2) + \sigma_{12}^2(y_2-\mu_2)^2 + \sigma_{22}^2(y_1-\mu_1)^2 - 2\sigma_{11}\sigma_{21}(y_1-\mu_1)(y_2-\mu_2) + \sigma_{11}^2(y_2-\mu_2)^2, \tag{20}$$

so

$$(x_1^2+x_2^2)(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2$$
$$= (y_1-\mu_1)^2(\sigma_{21}^2+\sigma_{22}^2) - 2(y_1-\mu_1)(y_2-\mu_2) \times (\sigma_{11}\sigma_{21} + \sigma_{12}\sigma_{22}) + (y_2-\mu_2)^2(\sigma_{21}^2+\sigma_{12}^2)$$
$$= \sigma_2^2(y_1-\mu_1)^2 - 2(y_1-\mu_1)(y_2-\mu_2)(\rho\sigma_1\sigma_2) + \sigma_1^2(y_2-\mu_2)^2$$
$$= \sigma_1^2\sigma_2^2\left[\frac{(y_1-\mu_1)^2}{\sigma_1^2} - \frac{2\rho(y_1-\mu_1)(y_2-\mu_2)}{\sigma_1\sigma_2} + \frac{(y_2-\mu_2)^2}{\sigma_2^2}\right]. \tag{21}$$

Now, the DENOMINATOR of (19) is

$$\sigma_{11}^2\sigma_{21}^2 + \sigma_{11}^2\sigma_{22}^2 + \sigma_{12}^2\sigma_{21}^2 + \sigma_{12}^2\sigma_{22}^2 - \sigma_{11}^2\sigma_{21}^2 - 2\sigma_{11}\sigma_{12}\sigma_{21}\sigma_{22} - \sigma_{12}^2\sigma_{22}^2$$
$$= (\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2, \tag{22}$$

so

$$\frac{1}{1-\rho^2} = \frac{1}{1 - \frac{V_{12}^2}{\sigma_1^2\sigma_2^2}} = \frac{\sigma_1^2\sigma_2^2}{\sigma_1^2\sigma_2^2 - V_{12}^2}$$
$$= \frac{\sigma_1^2\sigma_2^2}{(\sigma_{11}^2 + \sigma_{12}^2)(\sigma_{21}^2 + \sigma_{22}^2) - (\sigma_{11}\sigma_{21} + \sigma_{12}\sigma_{22})^2}. \tag{23}$$

can be written simply as

$$\frac{1}{1-\rho^2} = \frac{\sigma_1^2\sigma_2^2}{(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2}, \tag{24}$$

and

$$x_1^2 + x_2^2 = \frac{1}{1-\rho^2} \times \left[\frac{(y_1-\mu_1)^2}{\sigma_1^2} - \frac{2\rho(y_1-\mu_1)(y_2-\mu_2)}{\sigma_1\sigma_2} + \frac{(y_2-\mu_2)^2}{\sigma_2^2}\right]. \tag{25}$$

Solving for x_1 and x_2 and defining

$$\rho' \equiv \frac{\sigma_1\sigma_2\sqrt{1-\rho^2}}{\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21}} \tag{26}$$

gives

$$x_1 = \frac{\sigma_{22}(y_1 - \mu_1) - \sigma_{12}(y_2 - \mu_2)}{\rho'} \quad (27)$$

$$x_2 = \frac{-\sigma_{21}(y_1 - \mu_1) + \sigma_{11}(y_2 - \mu_2)}{\rho'}. \quad (28)$$

But the JACOBIAN is

$$J\left(\frac{x_1, x_2}{y_1, y_2}\right) = \begin{vmatrix} \frac{\partial x_1}{\partial y_1} & \frac{\partial x_1}{\partial y_2} \\ \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y_2} \end{vmatrix} = \begin{vmatrix} \frac{\sigma_{22}}{\rho'} & -\frac{\sigma_{12}}{\rho'} \\ -\frac{\sigma_{21}}{\rho'} & \frac{\sigma_{11}}{\rho'} \end{vmatrix}$$

$$= \frac{1}{\rho'^2}(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21}) = \frac{1}{\rho'} = \frac{1}{\sigma_1\sigma_2\sqrt{1-\rho^2}}, \quad (29)$$

so

$$dx_1\, dx_2 = \frac{dy_1 dy_2}{\sigma_1\sigma_2\sqrt{1-\rho^2}} \quad (30)$$

and

$$\frac{1}{2\pi} e^{-(x_1^2+x_2^2)/2}\, dx_1\, dx_2$$

$$= \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} \exp\left[-\frac{z}{2(1-\rho^2)}\right] dy_1\, dy_2, \quad (31)$$

where

$$z \equiv \frac{(y_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(y_1 - \mu_1)(y_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(y_2 - \mu_2)^2}{\sigma_2^2}. \quad (32)$$

Q.E.D.

In the singular case that

$$\begin{vmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{vmatrix} = 0 \quad (33)$$

(Kenney and Keeping 1951, p. 94), it follows that

$$\sigma_{11}\sigma_{12} = \sigma_{12}\sigma_{21} \quad (34)$$

$$y_1 = mu_1 + \sigma_{11}x_1 + \sigma_{12}x_2 \quad (35)$$

$$y_2 = \mu_1 + \frac{\sigma_{12}\sigma_{21}}{\sigma_{11}} x_2 = \mu_2 + \frac{\sigma_{11}\sigma_{21}x_1 + \sigma_{12}\sigma_{21}x_2}{\sigma_{11}}$$

$$= \mu_2 + \frac{\sigma_{21}}{\sigma_{11}}(\sigma_{11}x_1 + \sigma_{12}x_2), \quad (36)$$

so

$$y_1 = \mu_1 + x_3 \quad (37)$$

$$y_2 = \mu_2 + \frac{\sigma_{21}}{\sigma_{11}} x_3, \quad (38)$$

where

$$x_3 = y_1 - \mu_1 = \frac{\sigma_{11}}{\sigma_{21}}(y_2 - \mu_2). \quad (39)$$

The CHARACTERISTIC FUNCTION of the Gaussian bivariate distribution is given by

$$\phi(t_1, t_2) \equiv \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{i(t_1x_1+t_2x_2)} P(x_1, x_2)\, dx_1\, dx_2$$

$$= N\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{i(t_1x_1+t_2x_2)} \exp\left[-\frac{z}{2(1-\rho^2)}\right] dx_1\, dx_2, \quad (40)$$

where

$$z \equiv \left[\frac{(x_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1 - \mu_1)(x_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(x_2 - \mu_2)^2}{\sigma_2^2}\right] \quad (41)$$

and

$$N \equiv \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}}. \quad (42)$$

Now let

$$u \equiv x_1 - \mu_1 \quad (43)$$

$$w \equiv x_2 - \mu_2. \quad (44)$$

Then

$$\phi(t_1, t_2)$$

$$= N' \int_{-\infty}^{\infty}\left(e^{it_2w} \exp\left[-\frac{1}{2(1-\rho^2)}\frac{w^2}{\sigma_2^2}\right]\right)\int_{-\infty}^{\infty} e^v e^{t_1u}\, du dw, \quad (45)$$

where

$$v \equiv -\frac{1}{2(1-\rho^2)}\frac{1}{\sigma_1^2}\left[u^2 - \frac{2\rho\sigma_1 w}{\sigma_2}\, u\right]$$

$$N' \equiv \frac{e^{i(t_1\mu_1 + t_2\mu_2)}}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}}. \quad (46)$$

COMPLETE THE SQUARE in the inner integral

$$\int_{-\infty}^{\infty} \exp\left\{-\frac{1}{2(1-\rho^2)}\frac{1}{\sigma_1^2}\left[u^2 - \frac{2\rho\sigma_1 w}{\sigma_2}\, u\right]\right\} e^{t_1u}\, du$$

$$= \int_{-\infty}^{\infty} \exp\left\{-\frac{1}{2\sigma_1^2(1-\rho^2)}\left[u - \frac{\rho_1\sigma_1 w}{\sigma^2}\right]^2\right\}$$

$$\times\left\{\frac{1}{2\sigma_1^2(1-\rho^2)}\left(\frac{\rho_1\sigma_1 w}{\sigma_2}\right)^2\right\} e^{it_1u}\, du. \quad (47)$$

Rearranging to bring the exponential depending on w outside the inner integral, letting

$$v \equiv u - \rho\, \frac{\sigma_1 w}{\sigma_2}, \quad (48)$$

and writing

$$e^{it_1u} = \cos(t_1u) + i\sin(t_1u) \tag{49}$$

gives

$$\phi(t_1,\ t_2) = N' \int_{-\infty}^{\infty} e^{it_2w} \exp\left[-\frac{1}{2\sigma_2^2(1-\rho^2)}\ w^2\right]$$
$$\times\exp\left[\frac{\rho^2}{2\sigma_2^2(1-\rho^2)}\ w^2\right]\int_{-\infty}^{\infty}\exp\left[-\frac{1}{2\sigma_2^2(1-\rho^2)}\ v^2\right]$$
$$\times\left\{\cos\left[t_1\left(v+\frac{\rho\sigma_1 w}{\sigma_2}\right)\right]+i\sin\left[t_1\left(v+\frac{\rho\sigma_1 w}{\sigma_2}\right)\right]\right\}dvdw. \tag{50}$$

Expanding the term in braces gives

$$\left[\cos(t_1v)\cos\left(\frac{\rho\sigma_1wt_1}{\sigma_2}\right)-\sin(t_1v)\sin\left(\frac{\rho\sigma_1w}{\sigma_2t_1}\right)\right]$$
$$+i\left[\sin(t_1v)\cos\left(\frac{\rho\sigma_1w}{\sigma_2t_1}\right)+\cos(t_1v)\sin\left(\frac{\rho\sigma_1wt_1}{\sigma_2}\right)\right]$$
$$=\left[\cos\left(\frac{\rho\sigma_1wt_1}{\sigma_2}\right)+i\sin\left(\frac{\rho\sigma_1wt_1}{\sigma_2}\right)\right]$$
$$\times[\cos(t_1v)+i\sin(t_1v)]$$
$$=\exp\left(\frac{i\rho\sigma_1w}{\sigma_2}\ t_1\right)[\cos(t_1v)+i\sin(t_1v)]. \tag{51}$$

But $e^{-ax^2}\sin(bx)$ is ODD, so the integral over the sine term vanishes, and we are left with

$$\phi(t_1,\ t_2)=N'\int_{-\infty}^{\infty}e^{it_2w}\exp\left[-\frac{w^2}{2\sigma_2^2}\right]\exp\left[\frac{\rho^2w^2}{2\sigma_2^2(1-\rho^2)}\right]$$
$$\times\exp\left[\frac{i\rho\sigma_1wt_1}{\sigma_2}\right]dw\int_{-\infty}^{\infty}\exp\left[-\frac{v^2}{2\sigma_1^2(1-\rho^2)}\right]\cos(t_1v)\,dv$$
$$=N'\int_{-\infty}^{\infty}\exp\left[iw\left(t_2+t_1\left(\rho\ \frac{\sigma_1}{\sigma_2}\right)\right)\right]\exp\left[-\frac{w^2}{2\sigma_2^2}\right]dw$$
$$\int_{-\infty}^{\infty}\exp\left[-\frac{v^2}{2\sigma_1^2(1-\rho^2)}\right]\cos(t_1v)\,dv. \tag{52}$$

Now evaluate the GAUSSIAN INTEGRAL

$$\int_{-\infty}^{\infty}e^{ikx}e^{-ax^2}\,dx=\int_{-\infty}^{\infty}e^{-ax^2}\cos(kx)\,dx$$
$$=\sqrt{\frac{\pi}{a}}\,e^{-k^2/4a} \tag{53}$$

to obtain the explicit form of the CHARACTERISTIC FUNCTION,

$$\phi(t_1,\ t_2)=\frac{e^{i(t_1\mu_1+t_2+\mu_2)}}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}}$$
$$\times\left\{\sigma_2\sqrt{2\pi}\exp\left[-\tfrac{1}{4}\left(t_2+\rho\ \tfrac{\sigma_1}{\sigma_2}\ t_1\right)^2 2\sigma_2^2\right]\right\}$$
$$\times\left\{\sigma_1\sqrt{2\pi(1-p^2)}\exp[-\tfrac{2}{1}2\sigma_1^2(1-\rho^2)]\right\}$$
$$=e^{i(t_1\mu_1+t_2\mu_2)}\exp\{-\tfrac{1}{2}[t_2^2\sigma_2^2+2\rho\sigma_1\sigma_2t_1t_2+\rho^2\sigma_1^2t_1^2$$
$$+(1-\rho^2)\sigma_1^2t_1^2]\}$$
$$=\exp[i(t_1\mu_1+t_2\mu_2)-\tfrac{1}{2}(\sigma_1^2t_1^2+2\rho\sigma_1\sigma_2t_1t_2+\sigma_1^2t_1^2)]. \tag{54}$$

Gaussian Brackets

A notation published by Gauss in *Disquisitiones Arithmeticae* and defined by

$$[\ ]=1 \tag{1}$$

$$[a_1]=a_1 \tag{2}$$

$$[a_1,\ a_2]=[a_1]a_2+[\ ] \tag{3}$$

$$[a_1,\ a_2,\ \ldots,\ a_n]$$
$$=[a_1,\ a_2,\ \ldots,\ a_{n-1}]a_n+[a_1,\ a_2,\ \ldots,\ a_{n-2}]. \tag{4}$$

Gaussian brackets are useful for treating CONTINUED FRACTIONS because

$$\cfrac{1}{a_1+\cfrac{1}{a_2+\cfrac{1}{a_3+\ldots+\cfrac{1}{a_n}}}}=\frac{[a_2,\ an]}{[a_1,\ an]}. \tag{5}$$

The NOTATION $[x]$ conflicts with that of GAUSSIAN POLYNOMIALS and the NINT function.

Gaussian Coefficient

q-BINOMIAL COEFFICIENT

Gaussian Coordinate System

A coordinate system which has a METRIC satisfying $g_{ii} = -1$ and $\partial g_{ij}/\partial x_j = 0$.

Gaussian Curvature

An intrinsic property of a space independent of the coordinate system used to describe it. The Gaussian curvature of a REGULAR SURFACE in $\mathbb{R}^3$ at a point $\mathbf{p}$ is formally defined as

$$K(\mathbf{p}) = \det(S(\mathbf{p})), \tag{1}$$

where S is the SHAPE OPERATOR and det denotes the DETERMINANT.

If $\mathbf{x} : U \to \mathbb{R}^3$ is a REGULAR PATCH, then the Gaussian curvature is given by

$$K = \frac{eg - f^2}{EG - F^2}, \tag{2}$$

where E, F, and G are coefficients of the first FUNDAMENTAL FORM and e, f, and g are coefficients of the second FUNDAMENTAL FORM (Gray 1997, p. 377). The Gaussian curvature can be given entirely in terms of the first FUNDAMENTAL FORM

$$ds^2 = E\, du^2 + 2F\, du\, dv + G\, dv^2 \tag{3}$$

and the DISCRIMINANT

$$g \equiv EG - F^2 \tag{4}$$

by

$$K = \frac{1}{\sqrt{g}}\left[\frac{\partial}{\partial v}\left(\frac{\sqrt{g}}{E}\,\Gamma^2_{11}\right) - \frac{\partial}{\partial u}\left(\frac{\sqrt{g}}{E}\,\Gamma^2_{12}\right)\right], \tag{5}$$

where Γ^k_{ij} are the CONNECTION COEFFICIENTS. Equivalently,

$$K = \frac{1}{g^2}\begin{vmatrix} E & F & \frac{\partial F}{\partial v} - \frac{1}{2}\frac{\partial G}{\partial u} \\ F & G & \frac{1}{2}\frac{\partial G}{\partial v} \\ \frac{1}{2}\frac{\partial E}{\partial u} & k_{23} & k_{33} \end{vmatrix} - \frac{1}{g^2}\begin{vmatrix} E & F & \frac{1}{2}\frac{\partial E}{\partial v} \\ F & G & \frac{1}{2}\frac{\partial G}{\partial u} \\ \frac{1}{2}\frac{\partial E}{\partial v} & \frac{1}{2}\frac{\partial G}{\partial v} & 0 \end{vmatrix}, \tag{6}$$

where

$$k_{23} \equiv \frac{\partial F}{\partial u} - \frac{1}{2}\frac{\partial E}{\partial v} \tag{7}$$

$$k_{33} \equiv -\frac{1}{2}\frac{\partial^2 E}{\partial v^2} + \frac{\partial^2 F}{\partial u \partial v} - \frac{1}{2}\frac{\partial^2 G}{\partial u^2}. \tag{8}$$

Writing this out,

$$\begin{aligned} K = {} & \frac{1}{2g}\left[2\frac{\partial^2 F}{\partial u \partial v} - \frac{\partial^2 E}{\partial v^2} - \frac{\partial^2 G}{\partial u^2}\right] \\ & - \frac{G}{4g^2}\left[\frac{\partial E}{\partial u}\left(2\frac{\partial F}{\partial v} - \frac{\partial G}{\partial u}\right) - \left(\frac{\partial E}{\partial v}\right)^2\right] + \frac{F}{4g_2} \\ & \times\left[\frac{\partial E}{\partial u}\frac{\partial G}{\partial v} - 2\frac{\partial E}{\partial v}\frac{\partial G}{\partial u} + \left(2\frac{\partial F}{\partial u} - \frac{\partial E}{\partial v}\right)\left(2\frac{\partial F}{\partial v} - \frac{\partial G}{\partial u}\right)\right] \\ & - \frac{E}{4g^2}\left[\frac{\partial G}{\partial v}\left(2\frac{\partial F}{\partial u} - \frac{\partial E}{\partial v}\right) - \left(\frac{\partial G}{\partial u}\right)^2\right]. \end{aligned} \tag{9}$$

The Gaussian curvature is also given by

$$K = \frac{\det(\mathbf{x}_{uu}\mathbf{x}_u\mathbf{x}_v)\det(\mathbf{x}_{vv}\mathbf{x}_u\mathbf{x}_v) - [\det(\mathbf{x}_{uv}\mathbf{x}_u\mathbf{x}_v)]^2}{[|\mathbf{x}_u|^2|\mathbf{x}_v|^2 - (\mathbf{x}_u \cdot \mathbf{x}_v)^2]^2} \tag{10}$$

(Gray 1997, p. 380), as well as

$$K = \frac{[\hat{\mathbf{N}}\hat{\mathbf{N}}_1\hat{\mathbf{N}}_2]}{\sqrt{g}} = \frac{\epsilon^{ij}[\hat{\mathbf{N}}\hat{\mathbf{T}}\hat{T}_i]_j}{\sqrt{g}}, \tag{11}$$

where ϵ^{ij} is the LEVI-CIVITA SYMBOL, $\hat{\mathbf{N}}$ is the unit NORMAL VECTOR and $\hat{\mathbf{T}}$ is the unit TANGENT VECTOR. The Gaussian curvature is also given by

$$K = -\frac{R}{2} = \kappa_1\kappa_2 = \frac{1}{R_1R_2}, \tag{12}$$

where R is the CURVATURE SCALAR, κ_1 and κ_2 the PRINCIPAL CURVATURES, and R_1 and R_2 the PRINCIPAL RADII OF CURVATURE. For a MONGE PATCH with $z = h(u, v)$,

$$K = \frac{h_{uu}h_{vv} - h_{uv}^2}{(1 + h_u^2 + h_v^2)^2}. \tag{13}$$

The Gaussian curvature K and MEAN CURVATURE H satisfy

$$H^2 \geq K, \tag{14}$$

with equality only at UMBILIC POINTS, since

$$H^2 - K = \tfrac{1}{4}(\kappa_1 - \kappa_2)^2. \tag{15}$$

If $\mathbf{p}$ is a point on a REGULAR SURFACE $M \subset \mathbb{R}^3$ and $\mathbf{v_p}$ and $\mathbf{w_p}$ are tangent vectors to M at $\mathbf{p}$, then the Gaussian curvature of M at $\mathbf{p}$ is related to the SHAPE OPERATOR S by

$$S(\mathbf{v_p}) \times S(\mathbf{w_p}) = K(\mathbf{p})\mathbf{v_p} \times \mathbf{w_p}. \tag{16}$$

Let $\mathbf{Z}$ be a nonvanishing VECTOR FIELD on M which is everywhere PERPENDICULAR to M, and let V and W be VECTOR FIELDS tangent to M such that $V \times W = \mathbf{Z}$, then

$$K = \frac{\mathbf{Z} \cdot (D_V\mathbf{Z} \times D_W\mathbf{Z})}{2|\mathbf{Z}|^4} \tag{17}$$

(Gray 1997, p. 410).

For a SPHERE, the Gaussian curvature is $K = 1/a^2$. For EUCLIDEAN SPACE, the Gaussian curvature is $K = 0$. For GAUSS-BOLYAI-LOBACHEVSKY SPACE, the Gaussian curvature is $K = -1/a^2$. A FLAT SURFACE is a REGULAR SURFACE and special class of MINIMAL SURFACE on which Gaussian curvature vanishes everywhere.

A point $\mathbf{p}$ on a REGULAR SURFACE $M \in \mathbb{R}^3$ is classified based on the sign of $K(\mathbf{p})$ as given in the following table (Gray 1997, p. 375), where S is the SHAPE OPERATOR.

Sign	Point
$K(\mathbf{p}) > 0$	ELLIPTIC POINT
$K(\mathbf{p}) < 0$	HYPERBOLIC POINT
$K(\mathbf{p}) = 0$ but $S(\mathbf{p}) \neq 0$	PARABOLIC POINT
$K(\mathbf{p}) = 0$ and $S(\mathbf{p}) = 0$	PLANAR POINT

A surface on which the Gaussian curvature K is everywhere POSITIVE is called SYNCLASTIC, while a surface on which K is everywhere NEGATIVE is called ANTICLASTIC. Surfaces with constant Gaussian curvature include the CONE, CYLINDER, KUEN SURFACE, PLANE, PSEUDOSPHERE, and SPHERE. Of these, the CONE and CYLINDER are the only FLAT SURFACES OF REVOLUTION.

Gaussian Curve

GAUSSIAN DISTRIBUTION

Gaussian Differential Equation

HYPERGEOMETRIC DIFFERENTIAL EQUATION

Gaussian Distribution

The Gaussian probability distribution with MEAN μ and STANDARD DEVIATION σ is a normalized GAUSSIAN FUNCTION OF THE FORM

$$P(x) = \frac{1}{\sigma\sqrt{2\pi}}\, e^{-(x-\mu)^2/(2\sigma^2)}, \tag{1}$$

where $P(x)\,dx$ gives the probability that a variate with a Gaussian distribution takes on a value in the range $[x, x+dx]$. Statisticians commonly call this distribution the NORMAL DISTRIBUTION and, because of its curved flaring shape, social scientists refer to it as the "bell curve." The distribution $P(x)$ is properly normalized for $x \in (-\infty\ \infty)$ since

$$\int_{-\infty}^{\infty} P(x)\,dx = 1. \tag{2}$$

The cumulative DISTRIBUTION FUNCTION, which gives the probability that a variate will assume a value $\leq x$, is then the integral of the GAUSSIAN FUNCTION,

$$D(x) = \int_{-\infty}^{x} P(x)\,dx = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{x} e^{-(x-\mu)^2/(2\sigma^2)}\,dx. \tag{3}$$

Gaussian distributions have many convenient properties, so random variates with unknown distributions are often assumed to be Gaussian, especially in physics and astronomy. Although this can be a dangerous assumption, it is often a good approximation due to a surprising result known as the CENTRAL LIMIT THEOREM. This theorem states that the MEAN of any set of variates with any distribution having a finite MEAN and VARIANCE tends to the Gaussian distribution. Many common attributes such as test scores, height, etc., follow roughly Gaussian distributions, with few members at the high and low ends and many in the middle. Gaussian distributions are frequently invoked in situations where they may not be applicable. As Lippmann stated, "Everybody believes in the exponential law of errors: the experimenters, because they think it can be proved by mathematics; and the mathematicians, because they believe it has been established by observation" (Whittaker and Robinson 1967, p. 179).

Making the transformation

$$z \equiv \frac{x-\mu}{\sigma}, \tag{4}$$

so that $dz = dx/\sigma$, gives a variate with VARIANCE $\sigma^2 = 1$ and MEAN $\mu = 0$, transforming $P(x)\,dx$ into

$$P(z)\,dz = \frac{1}{\sqrt{2\pi}}\,e^{-z^2/2}\,dz. \quad (5)$$

The distribution having this probability function is known as a standard NORMAL DISTRIBUTION, and z defined in this way is known as a Z-SCORE.

The NORMAL DISTRIBUTION FUNCTION $\Phi(z)$ gives the probability that a standard normal variate assumes a value in the interval $[0, z]$,

$$\Phi(z) \equiv \frac{1}{\sqrt{2\pi}} \int_0^z e^{-x^2/2}\,dx = \tfrac{1}{2}\operatorname{erf}\left(\frac{z}{\sqrt{2}}\right), \quad (6)$$

where ERF is a function sometimes called the error function. Neither $\Phi(z)$ nor ERF can be expressed in terms of finite additions, subtractions, multiplications, and ROOT EXTRACTIONS, and so both must be either computed numerically or otherwise approximated. The value of a for which $P(x)$ falls within the interval $[-a, a]$ with a given probability P is called the P CONFIDENCE INTERVAL.

The Gaussian distribution is also a special case of the CHI-SQUARED DISTRIBUTION, since making the substitution

$$\tfrac{1}{2}z \equiv \frac{(x-\mu)^2}{2\sigma^2} \quad (7)$$

gives

$$d(\tfrac{1}{2}z) = \frac{(x-\mu)}{\sigma^2}\,dx = \frac{\sqrt{z}}{\sigma}\,dx. \quad (8)$$

Now, the real line $x \in (-\infty\ \infty)$ is mapped onto the half-infinite interval $z \in [0, \infty)$ by this transformation, so an extra factor of 2 must be added to $d(z/2)$, transforming $P(x)\,dx$ into

$$P(z)\,dz = \frac{1}{\sigma\sqrt{2\pi}}\,e^{-z/2}\,\frac{\sigma}{\sqrt{z}}\,2(\tfrac{1}{2}\,dz) = \frac{e^{-z/2}z^{-1/2}}{2^{1/2}\Gamma\left(\frac{1}{2}\right)}\,dz \quad (9)$$

(Kenney and Keeping 1951, p. 98), where use has been made of the identity $\Gamma(1/2) = \sqrt{\pi}$. As promised, (9) is a CHI-SQUARED DISTRIBUTION in z with $r = 1$ (and also a GAMMA DISTRIBUTION with $\alpha = 1/2$ and $(\theta = 2)$).

The ratio X/Y of independent Gaussian-distributed variates with zero MEAN is distributed with a CAUCHY DISTRIBUTION. This can be seen as follows. Let X and Y both have MEAN 0 and standard deviations of σ_x and σ_y, respectively, then the joint probability density function is the GAUSSIAN BIVARIATE DISTRIBUTION with $\rho = 0$,

$$f(x, y) = \frac{1}{2\pi\sigma_x\sigma_y}\,e^{-[x^2/(2\sigma_x^2)+y^2/(2\sigma_y^2)]}. \quad (10)$$

From RATIO DISTRIBUTION, the distribution of $U = Y/X$ is

$$P(u) = \int_{-\infty}^{\infty} |x| f(x, ux)\,dx$$
$$= \frac{1}{2\pi\sigma_x\sigma_y}\int_{-\infty}^{\infty} |x| e^{-[x^2/(2\sigma_x^2)+u^2x^2/(2\sigma_y^2)]}\,dx$$
$$= \frac{1}{\pi\sigma_x\sigma_y}\int_0^{\infty} x\exp\left[-x^2\left(\frac{1}{2\sigma_x^2}+\frac{u^2}{2\sigma_y^2}\right)\right]dx. \quad (11)$$

But

$$\int_0^{\infty} xe^{-ax^2}\,dx$$
$$= \left[-\frac{1}{2a}\,e^{-ax^2}\right]_0^{\infty} = \frac{1}{2a}[0-(-1)] = \frac{1}{2a}, \quad (12)$$

so

$$P(u) = \frac{1}{\pi\sigma_x\sigma_y}\,\frac{1}{2\left(\frac{1}{2\sigma_x^2}+\frac{u^2}{2\sigma_y^2}\right)} = \frac{1}{\pi}\,\frac{\sigma_x\sigma_y}{u^2\sigma_x^2+\sigma_y^2}$$
$$= \frac{1}{\pi}\,\frac{\frac{\sigma_y}{\sigma_x}}{u^2+\left(\frac{\sigma_y}{\sigma_x}\right)^2}, \quad (13)$$

which is a CAUCHY DISTRIBUTION with MEAN $\mu = 0$ and full width

$$\Gamma = \frac{2\sigma_y}{\sigma_x}. \quad (14)$$

The CHARACTERISTIC FUNCTION for the Gaussian distribution is

$$\phi(t) = e^{imt-\sigma^2t^2/2}, \quad (15)$$

and the MOMENT-GENERATING FUNCTION is

$$M(t) = \langle e^{tx}\rangle = \int_{-\infty}^{\infty} \frac{e^{tx}}{\sigma\sqrt{2\pi}}\,e^{-(x-\mu)^2/2\sigma^2}\,dx.$$
$$= \frac{1}{\sigma\sqrt{2\pi}}\int_{-\infty}^{\infty} \exp\left\{-\frac{1}{2\sigma^2}[x^2-2(\mu+\sigma^2t)x+\mu^2]\right\}dx. \quad (16)$$

COMPLETING THE SQUARE in the exponent,

$$\frac{1}{2\sigma^2}[x^2-2(\mu+\sigma^2t)x+\mu^2]$$
$$= \frac{1}{2\sigma^2}\{[x-(\mu+\sigma^2t)]^2+[\mu^2-(\mu+\sigma^2t)^2]\} \quad (17)$$

Let

$$y \equiv x-(\mu+\sigma^2t) \quad (18)$$

$$dy = dx \quad (19)$$

$$a \equiv \frac{1}{2\sigma^2}. \tag{20}$$

The integral then becomes

$$\begin{aligned} M(t) &= \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} \exp\left[-ay^2 + \frac{2\mu\sigma^2 t + \sigma^4 t^2}{2\sigma^2}\right] dy \\ &= \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} \exp[-ay^2 + \mu t + \tfrac{1}{2}\sigma^2 t^2]\, dy \\ &= \frac{1}{\sigma\sqrt{2\pi}} e^{\mu t + \sigma^2 t^2/2} \int_{-\infty}^{\infty} e^{-ay^2}\, dy \\ &= \frac{1}{\sigma\sqrt{2\pi}} \sqrt{\frac{\pi}{a}}\, e^{\mu t + \sigma^2 t^2/2} = \frac{\sqrt{2\sigma^2\pi}}{\sigma\sqrt{2\pi}} e^{\mu t + \sigma^2 t^2/2} \\ &= e^{\mu t + \sigma^2 t^2/2}, \end{aligned} \tag{21}$$

so

$$M'(t) = (\mu + \sigma^2 t) e^{\mu t + \sigma^2 t^2/2} \tag{22}$$

$$M'(t) = \sigma^2 e^{\mu t + \sigma^2 t^2/2} + e^{\mu t + \sigma^2 t^2/2} (\mu + t\sigma^2)^2, \tag{23}$$

and

$$\mu = M'(0) = \mu \tag{24}$$

$$\sigma^2 = M''(0) - [M'(0)]^2 = (\sigma^2 + \mu^2) - \mu^2 = \sigma^2. \tag{25}$$

These can also be computed using

$$R(t) = \ln[M(t)] = \mu t + \tfrac{1}{2}\sigma^2 t^2 \tag{26}$$

$$R'(t) = \mu + \sigma^2 t \tag{27}$$

$$R''(t) = \sigma^2, \tag{28}$$

yielding, as before,

$$\mu = R'(0) = \mu \tag{29}$$

$$\sigma^2 = R''(0) = \sigma^2. \tag{30}$$

The raw moments can also be computed directly by computing the MOMENTS about the origin $\mu'_n \equiv \langle x^n \rangle$,

$$\mu'_n = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} x^n e^{-(x-\mu)^2/2\sigma^2}\, dx. \tag{31}$$

(Papoulis 1984, pp. 147–48). Now let

$$u \equiv \frac{x - \mu}{\sqrt{2}\sigma} \tag{32}$$

$$du = \frac{dx}{\sqrt{2}\sigma} \tag{33}$$

$$x = \sigma u \sqrt{2} + \mu, \tag{34}$$

giving the raw moments in terms of GAUSSIAN INTEGRALS,

$$\mu'_n = \frac{\sqrt{2}\sigma}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} x^n e^{-u^2}\, du = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} x^n e^{-u^2}\, du. \tag{35}$$

Evaluating these integrals gives

$$\mu'_0 = 1 \tag{36}$$

$$\mu'_1 = \mu \tag{37}$$

$$\mu'_2 = \mu^2 + \sigma^2 \tag{38}$$

$$\mu'_3 = \mu(\mu^2 + 3\sigma^2) \tag{39}$$

$$\mu'_4 = \mu^4 + 6\mu^2\sigma^2 + 3\sigma^4. \tag{40}$$

Now find the MOMENTS about the MEAN,

$$\mu_1 = 0 \tag{41}$$

$$\mu_2 = \sigma^2 \tag{42}$$

$$\mu_3 = 0 \tag{43}$$

$$\mu_4 = 3\sigma^4, \tag{44}$$

so the VARIANCE, SKEWNESS, and KURTOSIS are given by

$$\mathrm{var}(x) = \sigma^2 \tag{45}$$

$$\gamma_1 = \frac{\mu_3}{\sigma^3} = 0 \tag{46}$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = \frac{3\sigma^4}{\sigma^4} - 3 = 0 \tag{47}$$

Cramer showed in 1936 that if X and Y are INDEPENDENT variates and $X + Y$ has a Gaussian distribution, then both X and Y must be Gaussian (CRAMER'S THEOREM). An easier result states that the sum of n variates each with is Gaussian distribution also has a Gaussian distribution. This follows from the result

$$P_n(x) = \mathcal{F}^{-1}\{[\phi(t)]^n\} = \frac{e^{-(x-n\mu)^2/(2n\sigma^2)}}{\sqrt{2\pi n\sigma^2}}, \tag{48}$$

where $\phi(t)$ is the CHARACTERISTIC FUNCTION and $\mathcal{F}^{-1}[f]$ is the inverse FOURIER TRANSFORM, taken with parameters $a = b = 1$.

The VARIANCE of the SAMPLE VARIANCE s^2 for a general distribution is given by

$$\mathrm{var}(s^2) = \frac{(N-1)[(N-1)\mu'_4 - (N-3)\mu'^2_2]}{N^3}, \tag{49}$$

which simplifies in the case of a Gaussian distribution to

$$\mathrm{var}(s^2) = \frac{2(N-1)(\mu^4 + 2N\mu^2\sigma^2 + N\sigma^4)}{N^3} \tag{50}$$

which, if $\mu = 0$, further simplifies to

$$\text{var}(s^2) = \frac{2\sigma^4(N-1)}{N^2} \tag{51}$$

(Kenney and Keeping 1951, p. 164).

The CUMULANT-GENERATING FUNCTION for a Gaussian distribution is

$$K(h) = \ln(e^{v1h}e^{\sigma^2h^2/2}) = v_1h + \tfrac{1}{2}\sigma^2h^2, \tag{52}$$

so

$$\kappa_1 = v_1 \tag{53}$$

$$\kappa_2 = \sigma^2 \tag{54}$$

$$\kappa_r = 0 \quad \text{for } r > 2. \tag{55}$$

For Gaussian variates, $\kappa_r = 0$ for $r > 2$, so the variance of K-STATISTIC k_3 is

$$\text{var}(k_3) = \frac{\kappa_6}{N} + \frac{9\kappa_2\kappa_4}{N-1} + \frac{9\kappa_3^2}{N-1} + \frac{6\kappa_2^3}{N(N-1)(N-2)}$$
$$= \frac{6\kappa_2^3}{N(N-1)(N-2)}. \tag{56}$$

Also,

$$\text{var}(k_4) = \frac{24k_2^4N(N-1)^2}{(N-3)(N-2)(N+3)(N+5)} \tag{57}$$

$$\text{var}(g_1) = \frac{6N(N-1)}{(N-2)(N+1)(N+3)} \tag{58}$$

$$\text{var}(g_2) = \frac{24N(N-1)^2}{(N-3)(N-2)(N+3)(N+5)}, \tag{59}$$

where

$$g_1 \equiv \frac{k_3}{k_2^{3/2}} \tag{60}$$

$$g_2 \equiv \frac{k_4}{k_2^2}. \tag{61}$$

If $P(x)$ is a Gaussian distribution, then

$$D(x) = \frac{1}{2}\left[1 + \text{erf}\left(\frac{x-\mu}{\sigma\sqrt{2}}\right)\right], \tag{62}$$

so variates x_i with a Gaussian distribution can be generated from variates y_i having a UNIFORM DISTRIBUTION in (0,1) via

$$x_i = \sigma\sqrt{2}\,\text{erf}^{-1}(2y_i - 1) + \mu. \tag{63}$$

However, a simpler way to obtain numbers with a Gaussian distribution is to use the BOX-MULLER TRANSFORMATION.

The Gaussian distribution is an approximation to the BINOMIAL DISTRIBUTION in the limit of large numbers,

$$P(n_1) = \frac{1}{\sqrt{2\pi Npq}} \exp\left[-\frac{(n_1 - Np)^2}{2Npq}\right], \tag{64}$$

where n_1 is the number of steps in the POSITIVE direction, N is the number of trials ($(N \equiv n_1 + n_2)$), and p and q are the probabilities of a step in the POSITIVE direction and NEGATIVE direction ($(q \equiv 1 - p)$).

The differential equation having a Gaussian distribution as its solution is

$$\frac{dy}{dx} = \frac{y(\mu - x)}{\sigma^2}, \tag{65}$$

since

$$\frac{dy}{y} = \frac{\mu - x}{\sigma^2}\,dx \tag{66}$$

$$\ln\left(\frac{y}{yo}\right) = -\frac{1}{2\sigma^2}(\mu - x)^2 \tag{67}$$

$$y = y_0e^{-(x-\mu)^2/2\sigma^2}. \tag{68}$$

This equation has been generalized to yield more complicated distributions which are named using the so-called PEARSON SYSTEM.

Gaussian Distribution Linear Combination of Variates

If x is NORMALLY DISTRIBUTED with MEAN μ and VARIANCE σ^2, then a linear function of x,

$$y = ax + b, \tag{1}$$

is also NORMALLY DISTRIBUTED. The new distribution has MEAN $a\mu + b$ and VARIANCE $a^2\sigma^2$, as can be

derived using the MOMENT-GENERATING FUNCTION

$$M(t) = \langle e^{t(ax+b)} \rangle = e^{tb} \langle e^{atx} \rangle = e^{tb} e^{\mu at + \sigma^2 (at)^2/2}$$

$$e^{tb+\mu at + \sigma^2 a^2 t^2/2} = e^{(b+a\mu)t + a^2\sigma^2 t^2/2}, \quad (2)$$

which is of the standard form with

$$\mu' = b + a \quad (3)$$

$$\sigma'^2 = a^2 \sigma^2. \quad (4)$$

For a weighted sum of independent variables

$$y \equiv \sum_{i=1}^{n} a_i x_i, \quad (5)$$

the expectation is given by

$$M(t) = \langle e^{yt} \rangle = \left\langle \exp\left(t \sum_{i=1}^{n} a_i x_i \right) \right\rangle$$

$$= \langle e^{a_1 t x_1} e^{a_2 t x_2} \cdots e^{a_n t x_n} \rangle = \prod_{i=1}^{n} \langle e^{a_i t x_i} \rangle$$

$$= \prod_{i=1}^{n} \exp(a_i \mu_i t + \tfrac{1}{2} a_i^2 \sigma_i^2 t^2). \quad (6)$$

Setting this equal to

$$\exp(\mu t + \tfrac{1}{2} \sigma^2 t^2) \quad (7)$$

gives

$$\mu \equiv \sum_{i=1}^{n} a_i \mu_i \quad (8)$$

$$\sigma^2 \equiv \sum_{i=1}^{n} a_i^2 \sigma_i^2. \quad (9)$$

Therefore, the MEAN and VARIANCE of the weighted sums of n RANDOM VARIABLES are their weighted sums.

If x_i are INDEPENDENT and NORMALLY DISTRIBUTED with MEAN 0 and VARIANCE σ^2, define

$$y_i \equiv \sum_j c_{ij} x_j, \quad (10)$$

where c obeys the ORTHOGONALITY CONDITION

$$c_{ik} c_{jk} = \delta_{ij}, \quad (11)$$

with δ_{ij} the KRONECKER DELTA. Then y_i are also independent and normally distributed with MEAN 0 and VARIANCE σ^2.

Gaussian Elimination

A method for solving MATRIX EQUATIONS OF THE FORM

$$\mathsf{A}\mathbf{x} = \mathbf{b}. \quad (1)$$

To perform Gaussian elimination starting with the system of equations

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_k \end{bmatrix}, \quad (2)$$

compose the "augmented matrix equation"

$$\left[\begin{array}{cccc|c} a_{11} & a_{12} & \cdots & a_{1k} & b_1 \\ a_{21} & a_{22} & \cdots & a_{2k} & b_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} & b_k \end{array}\right] \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix}. \quad (3)$$

Here, the COLUMN VECTOR in the variables $\mathbf{x}$ is carried along for labeling the matrix rows. Now, perform ELEMENTARY ROW AND COLUMN OPERATIONS to put the augmented matrix into the UPPER TRIANGULAR form

$$\left[\begin{array}{cccc|c} a'_{11} & a'_{12} & \cdots & a'_{1k} & b'_1 \\ 0 & a'_{22} & \cdots & a'_{2k} & b'_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & a'_{kk} & b'_k \end{array}\right]. \quad (4)$$

Solve the equation of the kth row for x_k, then substitute back into the equation of the $(k-1)$st row to obtain a solution for x_{k-1}, etc., according to the formula

$$x_i = \frac{1}{a'_{ii}} \left(b'_i - \sum_{j=i+1}^{k} a'_{ij} x_j \right). \quad (5)$$

For example, consider the MATRIX EQUATION

$$\begin{bmatrix} 9 & 3 & 4 \\ 4 & 3 & 4 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 7 \\ 8 \\ 3 \end{bmatrix}. \quad (6)$$

In augmented form, this becomes

$$\left[\begin{array}{ccc|c} 9 & 3 & 4 & 7 \\ 4 & 3 & 4 & 8 \\ 1 & 1 & 1 & 3 \end{array}\right] \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}. \quad (7)$$

Switching the first and third rows gives

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & 3 \\ 4 & 3 & 4 & 8 \\ 9 & 3 & 4 & 7 \end{array}\right] \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}. \quad (8)$$

Subtracting 9 times the first row from the third row gives

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & 3 \\ 4 & 3 & 4 & 8 \\ 0 & -6 & -5 & -20 \end{array}\right]\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}. \qquad (9)$$

Subtracting 4 times the first row from the second row gives

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & 3 \\ 0 & -1 & 0 & -4 \\ 0 & -6 & -5 & -20 \end{array}\right]\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}. \qquad (10)$$

Finally, adding -6 times the second column to the third one gives

$$\left[\begin{array}{ccc|c} 1 & 1 & 1 & 3 \\ 0 & -1 & 0 & -4 \\ 0 & 0 & -5 & 4 \end{array}\right]\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}. \qquad (11)$$

Restoring the transformed matrix equation gives

$$\begin{bmatrix} 1 & 1 & 1 \\ 0 & -1 & 0 \\ 0 & 0 & -5 \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 3 \\ -4 \\ 4 \end{bmatrix}, \qquad (12)$$

which can be solved immediately to give $x_3 = -4/5$, back-substituting to obtain $x_2 = 4$ (which actually follows trivially in this example), and then again back-substituting to find $x_1 = -1/5$

Gaussian Function

In 1-D, the Gaussian function is the function from the Gaussian distribution,

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/2\sigma^2}, \qquad (1)$$

sometimes also called the frequency curve. The full width at half maximum (FWHM) for a Gaussian is found by finding the half-maximum points x_0. The constant scaling factor can be ignored, so we must solve

$$e^{-(x_0-\mu)^2/2\sigma^2} = \tfrac{1}{2} f(x_{\max}) \qquad (2)$$

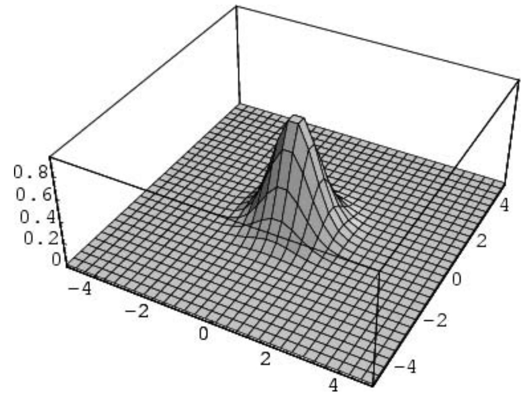
But $f(x_{\max})$ occurs at $x_{\max} = \mu$, so

$$e^{-(x_0-\mu)^2/2\sigma^2} = \tfrac{1}{2} f(\mu) = \tfrac{1}{2}. \qquad (3)$$

Solving,

$$e^{-(x_0-\mu)^2/2\sigma^2} = 2^{-1} \qquad (4)$$

$$-\frac{(x_0-\mu)^2}{2\sigma^2} = -\ln 2 \qquad (5)$$



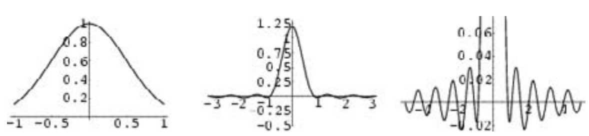
$$(x_0-\mu)^2 = 2\sigma^2 \ln 2 \qquad (6)$$

$$x_0 \pm \sigma\sqrt{2 \ln 2} + \mu. \qquad (7)$$

The full width at half maximum is therefore given

by

$$\text{FWHM} \equiv x_+ - x = 2\sqrt{2 \ln 2}\sigma \approx 2.3548\sigma. \tag{8}$$



In 2-D, the circular Gaussian function is the distribution function for uncorrelated variables x and y having a GAUSSIAN BIVARIATE DISTRIBUTION and equal STANDARD DEVIATION $\sigma = \sigma_x = \sigma_y$,

$$f(x, y) = \frac{1}{2\pi\sigma^2} e^{-[(x-\mu_z)^2+(y-\mu_y)^2]/2\sigma^2}. \tag{9}$$

The corresponding elliptical Gaussian function corresponding to $\sigma_x \neq \sigma_y$ is given by

$$f(x, y) = \frac{1}{2\pi\sigma_x\sigma_y} e^{-[(x-\mu_z)^2/2\sigma_z^2+(y-\mu_y)^2/2\sigma_y^2]}. \tag{10}$$

The Gaussian function can also be used as an APODIZATION FUNCTION, shown above with the corresponding INSTRUMENT FUNCTION.

The HYPERGEOMETRIC FUNCTION is also sometimes known as the Gaussian function.

Gaussian Hypergeometric Series

HYPERGEOMETRIC FUNCTION

Gaussian Integer

A COMPLEX NUMBER $a+bi$ where a and b are INTEGERS. The Gaussian integers are members of the IMAGINARY QUADRATIC FIELD $\mathbb{Q}(\sqrt{-1})$ and form a RING often denoted $\mathbb{Z}[i]$. The sum, difference, and product of two Gaussian integers are Gaussian integers, but $(a+bi)|(c+di)$ only if there is an $e+fi$ such that

$$(a+bi)(e+fi) = (ae-bf) + (af+be)i = c+di.$$

Gaussian integers can be uniquely factored in terms of other Gaussian integers (known as GAUSSIAN PRIMES) up to POWERS of i and rearrangements. The units of $\mathbb{Z}[i]$ are ± 1 and $\pm i$, and the norm of a Gaussian integer is defined by

$$n(x+iy) = x^2 + y^2.$$

Every Gaussian integer is within $|n|/\sqrt{2}$ of a multiple of a Gaussian integer n.

Gaussian Integral

The Gaussian integral, also called the PROBABILITY INTEGRAL and closely related to the ERF function, is the integral of the 1-D GAUSSIAN FUNCTION over $(-\infty, \infty)$. It can be computed using the trick of combining two 1-D Gaussians

$$\int_{-\infty}^{\infty} e^{-x^2}\,dx = \sqrt{\left(\int_{-\infty}^{\infty} e^{-y^2}\,dy\right)\left(\int_{-\infty}^{\infty} e^{-x^2}\,dx\right)} = \sqrt{\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-(x^2+y^2)}dy\,dx} \tag{1}$$

and switching to POLAR COORDINATES,

$$\int_{-\infty}^{\infty} e^{-x^2}\,dx = \sqrt{\int_0^{2\pi}\int_0^{\infty} e^{-r^2} r\,dr\,d\theta} = \sqrt{2\pi\left[-\tfrac{1}{2}e^{-r^2}\right]_0^{\infty}} = \sqrt{\pi}. \tag{2}$$

However, a simple proof can also be given which does not require transformation to POLAR COORDINATES (Nicholas and Yates 1950).

The integral from 0 to a finite upper limit a can be given by the CONTINUED FRACTION

$$\int_0^a e^{-t^2} dt = \tfrac{1}{2}\sqrt{\pi}\,\text{erf}\,a$$

$$\tfrac{1}{2}\sqrt{\pi} - \frac{e^{-a^2}}{2a+}\,\frac{1}{a+}\,\frac{2}{2a}\,\frac{3}{a+}\,\frac{4}{2a+\ldots}, \tag{3}$$

first stated by Laplace, proved by Jacobi, and rediscovered by Ramanujan (Watson 1928; Hardy 1999, pp. 8–).

The general class of integrals OF THE FORM

$$I_n(a) \equiv \int_0^\infty e^{-ax^2} x^n \, dx \tag{4}$$

can be solved analytically by setting

$$x \equiv a^{-1/2} y \tag{5}$$

$$dx = a^{-1/2} dy \tag{6}$$

$$y^2 = ax^2. \tag{7}$$

Then

$$\begin{aligned} I_n(a) &= a^{-1/2} \int_0^\infty e^{-y^2} (a^{-1/2} y)^n \, dy \\ &= a^{-(n+1)/2} \int_0^\infty e^{-y^2} y^n \, dy. \end{aligned} \tag{8}$$

For $n=0$, this is just the usual Gaussian integral, so

$$I_0(a) = \frac{\sqrt{\pi}}{2} a^{-1/2} = \frac{1}{2}\sqrt{\frac{\pi}{a}}. \tag{9}$$

For $n=1$, the integrand is integrable by quadrature,

$$I_1(a) = a^{-1} \int_0^\infty e^{-y2} y \, dy = a^{-1} \left[-\tfrac{1}{2} e^{-y^2} \right]_0^\infty = \tfrac{1}{2} a^{-1}. \tag{10}$$

To compute $I_n(a)$ for $n > 1$, use the identity

$$\begin{aligned} -\frac{\partial}{\partial a} I_{n-2}(a) &= -\frac{\partial}{\partial a} \int_0^\infty e^{-ax^2} x^{n-2} \, dx \\ &= -\int_0^\infty -x^2 e^{-ax^2} x^{n-2} \, dx \\ &= \int_0^\infty e^{-ax^2} x^n \, dx = I_n(a). \end{aligned} \tag{11}$$

For $n = 2s$ EVEN,

$$\begin{aligned} I_n(a) &= \left(-\frac{\partial}{\partial a}\right) I_{n-2}(a) = \left(-\frac{\partial}{\partial a}\right)^2 I_{n-4} \\ &= \ldots = \left(-\frac{\partial}{\partial a}\right)^{n/2} I_0(a) \\ &= \frac{\partial^{n/2}}{\partial a^{n/2}} I_0(a) = \frac{\sqrt{\pi}}{2} \frac{\partial^{n/2}}{\partial a^{n/2}} a^{-1/2}, \end{aligned} \tag{12}$$

so

$$\int_0^\infty x^{2s} e^{-ax^2} \, dx = \frac{(s-\frac{1}{2})!}{2a^{s+1/2}} = \frac{(2s-1)!!}{2^{s+1} a^s} \sqrt{\frac{\pi}{a}}. \tag{13}$$

If $n = 2s+1$ is ODD, then

$$\begin{aligned} I_n(a) &= \left(-\frac{\partial}{\partial a}\right) I_{n-2}(a) = \left(-\frac{\partial}{\partial a}\right)^2 I_{n-4}(a) \\ &= \ldots = \left(-\frac{\partial}{\partial a}\right)^{(n-1)/2} I_1(a) \\ &= \frac{\partial^{(n-1)/2}}{\partial a^{(n-1)/2}} I_1(a) = \frac{1}{2} \frac{\partial^{(n-1)/2}}{\partial a^{(n-1)/2}} a^{-1}, \end{aligned} \tag{14}$$

so

$$\int_0^\infty x^{2s+1} e^{-ax^2} \, dx = \frac{s!}{2a^{s+1}}. \tag{15}$$

The solution is therefore

$$\int_0^\infty e^{-ax^2} x^n \, dx = \begin{cases} \dfrac{(n-1)!!}{2^{n/2+1} a^{n/2}} \sqrt{\dfrac{\pi}{a}} & \text{for } n \text{ even} \\ \dfrac{\left[\frac{1}{2}(n-1)\right]!}{2a^{(n+1/2)}} & \text{for } n \text{ odd.} \end{cases} \tag{16}$$

The first few values are therefore

$$I_0(a) = \frac{1}{2}\sqrt{\frac{\pi}{a}} \tag{17}$$

$$I_1(a) = \frac{1}{2a} \tag{18}$$

$$I_2(a) = \frac{1}{4a}\sqrt{\frac{\pi}{a}} \tag{19}$$

$$I_3(a) = \frac{1}{2a^2} \tag{20}$$

$$I_4(a) = \frac{3}{8a^2}\sqrt{\frac{\pi}{a}} \tag{21}$$

$$I_5(a) = \frac{1}{a^3} \tag{22}$$

$$I_6(a) = \frac{15}{16a^3}\sqrt{\frac{\pi}{a}}. \tag{23}$$

A related, often useful integral is

$$H_n(a) \equiv \frac{1}{\sqrt{\pi}} \int_{-\infty}^\infty e^{-ax^2} x^n \, dx, \tag{24}$$

which is simply given by

$$H_n(a) = \begin{cases} \frac{2I_n(a)}{\sqrt{\pi}} & \text{for } n \text{ even} \\ 0 & \text{for } n \text{ odd.} \end{cases} \quad (25)$$

The more general integral of $x^n e^{-ax^2+bx}$ has the following closed forms

$$\int_{-\infty}^{\infty} x^n e^{-ax^2+bx}\, dx$$
$$= i^{-n} a^{-(n+1)/2} \sqrt{\pi}\, e^{b^2/(4a)} U(-\tfrac{1}{2}n;\ \tfrac{1}{2};\ -b^2/4a) \quad (26)$$

$$= \sqrt{\frac{\pi}{a}} e^{b^2/(4a)} \sum_{k=0}^{n-1} \frac{n!}{k!(n-2k)!} \frac{(2b)^{n-2k}}{(4a)^{n-k}} \quad (27)$$

$$= \sqrt{\frac{\pi}{a}} e^{b^2/(4a)} \sum_{k=0}^{n-1} \binom{n}{2k} (2k-1)!!(2a)^{k-n} b^{n-2k} \quad (28)$$

for integer $n > 0$ (F. Pilolli), where $U(a;\ b;\ x)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

Gaussian Joint Variable Theorem

Also called the MULTIVARIATE THEOREM. Given an EVEN number of variates from a NORMAL DISTRIBUTION with MEANS all 0,

$$\langle x_1 x_2 \rangle = \langle x_1 \rangle \langle x_2 \rangle, \quad (1)$$

$$\langle x_1 x_2 x_3 x_4 \rangle = \langle x_1 x_2 \rangle \langle x_3 x_4 \rangle + \langle x_1 x_3 \rangle \langle x_2 x_4 \rangle + \langle x_1 x_4 \rangle \langle x_2 x_3 \rangle, \quad (2)$$

etc. Given an ODD number of variates,

$$\langle x_1 \rangle = 0, \quad (3)$$

$$\langle x_1 x_2 x_3 \rangle = 0, \quad (4)$$

etc.

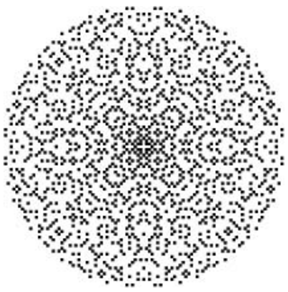
Gaussian Mountain Range

CAROTID-KUNDALINI FUNCTION

Gaussian Multinormal Distribution

GAUSSIAN MULTIVARIATE DISTRIBUTION

Gaussian Multivariate Distribution



A Gaussian p-variate multinormal (or multivariate) distribution is a generalization of the GAUSSIAN BIVARIATE DISTRIBUTION. The p-multivariate distribution with mean vector μ and COVARIANCE MATRIX Σ is denoted $N_p(\mu$, Sigma). The Gaussian multivariate distribution is implemented in *Mathematica* as `MultinormalDistribution[{`*mu1*, *mu2*, ...}, {{*sigma11*, *sigma12*, ...}, {*sigma12*, *sigma22*, ...}...}, {*x1*, *x2*, ...}] in the *Mathematica* add-on package `Statistics`MultinormalDistribution`` (which can be loaded with the command `<<Statistics``) (where the matrix Σ is symmetrical since $\sigma_{ij} = \sigma ji$).

See also GAUSSIAN BIVARIATE DISTRIBUTION, GAUSSIAN DISTRIBUTION, JOINT THEOREM, MULTIVARIATE THEOREM

Gaussian Polynomial

Q-BINOMIAL COEFFICIENT, *Q*-BRACKET

Gaussian Prime

Gaussian primes are GAUSSIAN INTEGERS $z = a + bi$ satisfying one of the following properties.

1. If both a and b are nonzero then, $a + bi$ is a Gaussian prime IFF $a^2 + b^2$ is an ordinary PRIME.
2. If $a = 0$, then bi is a Gaussian prime IFF $|b|$ is an ordinary PRIME and $b \equiv 3$.
3. If $b = 0$, then a is a Gaussian prime IFF $|a|$ is an ordinary PRIME and $a \equiv 3$.

The above plot of the COMPLEX PLANE shows the Gaussian primes as filled squares.

The primes which are also Gaussian primes are 3, 7, 11, 19, 23, 31, 43, ... (Sloane's A002145). The Gaussian primes with $|a|$, $|b| \leq 5$ are given by $-5-4i$, $-5-2i$, $-5+2i$, $-5+4i$, $-4-5i$, $-4-i$, $-4+i$, $-4+5i$, $-3-2i$, -3, $-3+2i$, $-2-5i$, $-2-3i$, $-2-i$, $-2+i$, $-2+3i$, $-2+5i$, $-1-4i$, $-1-2i$, $-1-i$, $-1+i$, $-1+2i$, $-1+4i$, $-3i$, $3i$, $1-4i$, $1-2i$, $1-i$, $1+i$, $1+2i$, $1+$

$4i, 2-5i, 2-3i, 2-i, 2+i, 2+3i, 2+5i, 3-2i, 3, 3+2i, 4-5i, 4-i, 4+i, 4+5i, 5-4i, 5-2i, 5+2i, 5+4i.$

Gaussian Quadrature

Seeks to obtain the best numerical estimate of an integral by picking optimal ABSCISSAS x_i at which to evaluate the function $f(x)$. The FUNDAMENTAL THEOREM OF GAUSSIAN QUADRATURE states that the optimal ABSCISSAS of the m-point GAUSSIAN QUADRATURE FORMULAS are precisely the roots of the orthogonal POLYNOMIAL for the same interval and WEIGHTING FUNCTION. Gaussian quadrature is optimal because it fits all POLYNOMIALS up to degree $2m$ exactly. Slightly less optimal fits are obtained from RADAU QUADRATURE and LAGUERRE QUADRATURE.

$W(x)$	interval	x_i are roots of
1	$(-1,\ 1)$	$P_n(x)$
e^{-t}	$(0,\ \infty)$	$L_n(x)$
e^{-t2}	$(-\infty,\ \infty)$	$H_n(x)$
$(1-t^2)^{-1/2}$	$(-1,\ 1)$	$T_n(x)$
$(1-t^2)^{1/2}$	$(-1,\ 1)$	$U_n(x)$
$x^{1/2}$	$(0,\ 1)$	$x^{-1/2}P_{2n+1}(\sqrt{x})$
$x^{-1/2}$	$(0,\ 1)$	$P_n(\sqrt{x})$

To determine the weights corresponding to the Gaussian ABSCISSAS x_i, compute a LAGRANGE INTERPOLATING POLYNOMIAL for $f(x)$ by letting

$$\pi(x)=\prod_{j=1}^{m}(x-x_j) \tag{1}$$

(where Chandrasekhar 1967 uses F instead of π), so

$$\pi'(x_j)=\left[\frac{d\pi}{dx}\right]_{x=x_j}=\prod_{\substack{i=1\\ i\neq j}}^{m}(x_j-x_i). \tag{2}$$

Then fitting a LAGRANGE INTERPOLATING POLYNOMIAL through the m points gives

$$\phi(x)=\sum_{j=1}^{m}\frac{\pi(x)}{(x-x_j)\pi'(x_j)}f(x_j) \tag{3}$$

for arbitrary points x. We are therefore looking for a set of points x_j and weights w_j such that for a WEIGHTING FUNCTION $W(x)$,

$$\int_a^b \phi(x)W(x)\,dx=\int_a^b\sum_{j=1}^{m}\frac{\pi(x)W(x)}{(x-x_j)\pi'(x_j)}\,dx\,f(x_j)$$
$$\equiv\sum_{j=1}^{m}w_jf(x_j), \tag{4}$$

with WEIGHT

$$w_j=\frac{1}{\pi'(x_j)}\int_a^b\frac{\pi(x)W(x)}{x-x_j}\,dx. \tag{5}$$

The weights w_j are sometimes also called the CHRISTOFFEL NUMBER (Chandrasekhar 1967). For orthogonal POLYNOMIALS $\phi_j(x)$ with $j=1, ..., n$,

$$\phi_j(x)=A_j\pi(x) \tag{6}$$

(Hildebrand 1956, p. 322), where A_n is the COEFFICIENT of x^n in $\phi_n(x)$, then

$$w_j=\frac{1}{\phi_n'(x_j)}\int_a^b W(x)\,\frac{\phi(x)}{x-x_j}\,dx$$
$$=-\frac{A_{n+1}\gamma_n}{A_n\phi_n'(x_j)\phi_{n+1}(x)}, \tag{7}$$

where

$$\gamma_m=\int[\phi_m(x)]^2W(x)\,dx. \tag{8}$$

Using the relationship

$$\phi_{n+1}(x_i)=-\frac{A_{n+1}A_{n-1}}{A_n^2}\,\frac{\gamma_n}{\gamma_{n-1}}\,\phi_{n-1}(x_i) \tag{9}$$

(Hildebrand 1956, p. 323) gives

$$w_j=\frac{A_n}{A_{n-1}}\,\frac{\gamma_{n-1}}{\phi_n'(x_j)\phi_{n-1}(x_j)}. \tag{10}$$

(Note that Press *et al.* 1992 omit the factor A_n/A_{n-1}.)

In Gaussian quadrature, the weights are all POSITIVE. The error is given by

$$E_n = \frac{f^{(2n)}(\xi)}{(2n)!} \int_a^b W(x)[\pi(x)]^2\, dx = \frac{\gamma_n}{A_n^2} \frac{f^{(2n)}(\xi)}{(2n)!}, \qquad (11)$$

where $a < \xi < b$ (Hildebrand 1956, pp. 320–21).

Other curious identities are

$$\sum_{k=0}^{m} \frac{[\phi_k(x)]^2}{\gamma^k} = \frac{A_m}{A_{m+1}\gamma_m} [\phi'_{m+1}(x)\phi_m(x) - \phi'_m(x)\phi_{m+1}(x)] \qquad (12)$$

and

$$\sum_{k=0}^{m} \frac{[\phi_k(x)]^2}{\gamma^k} = -\frac{A_m \phi'_m(x_i)\phi_{m+1}(x_i)}{A_{m+1}\gamma_m} = \frac{1}{w_i} \qquad (13)$$

(Hildebrand 1956, p. 323).

In the NOTATION of Szego (1975), let $x_{1n} < \ldots < x_{nn}$ be an ordered set of points in $[a, b]$, and let $\lambda_{1n}, \ldots, \lambda_{nn}$ be a set of REAL NUMBERS. If $f(x)$ is an arbitrary function on the CLOSED INTERVAL $[a, b]$, write the MECHANICAL QUADRATURE as

$$Q_n(f) = \sum_{\nu=1}^{n} \lambda_{\nu n} f(x_{\nu n}). \qquad (14)$$

Here $x_{\nu n}$ are the ABSCISSAS and $\lambda_{\nu n}$ are the COTES NUMBERS.

Gaussian Sum

A sum OF THE FORM

$$S(p, q) \equiv \sum_{r=0}^{q-1} e^{-\pi i r^2 p/q}, \qquad (1)$$

where p and q are RELATIVELY PRIME INTEGERS. The symbol φ is sometimes used instead of S. Although the restriction to RELATIVELY PRIME INTEGERS is often useful, it is not necessary, and Gaussian sums can be written so as to be valid for all integer q (Borwein and Borwein 1987, pp. 83 and 86).

If $(n, n') = 1$, then

$$S(m, nn') = S(mn', n)S(mn, n') \qquad (2)$$

(Nagell 1951, p. 178). Gauss showed that

$$S(1, q) = \frac{1 - i^q}{1 - i} \sqrt{q} \qquad (3)$$

for ODD q. Written explicitly

$$S(1, q) = \begin{cases} (i+1)\sqrt{q} & \text{for } q \equiv 0 \pmod 4 \\ \sqrt{q} & \text{for } q \equiv 1 \pmod 4 \\ 0 & \text{for } q \equiv 2 \pmod 4 \\ i\sqrt{q} & \text{for } q \equiv 3 \pmod 4 \end{cases} \qquad (4)$$

(Nagell 1951, p. 177).

For p and q of opposite PARITY (i.e., one is EVEN and the other is ODD), SCHAAR'S IDENTITY states

$$\frac{1}{\sqrt{q}} \sum_{r=0}^{q-1} e^{-\pi i r^2/q} = \frac{e^{-\pi i/4}}{\sqrt{p}} \sum_{r=0}^{p-1} e^{\pi i r^2 q/p}. \qquad (5)$$

Such sums are important in the theory of QUADRATIC RESIDUES.

Gauss-Jackson Method

A method for numerical solution of a second-order ordinary differential equation

$$y'' = f(x, y)$$

first expounded by Gauss. It proceeds by introducing a function $\delta^{-2}f$ whose second differences are f. The advantage of this method is that summation to get δ^{-2} can be done exactly and that each rounding-off error in the correction term arises only a single time (Jeffreys and Jeffreys 1988, p. 300).

Gauss-Jacobi Mechanical Quadrature

If $x_1 < x_2 < \ldots < x_n$ denote the zeros of $p_n(x)$, there exist REAL NUMBERS $\lambda_1, \lambda_2, \ldots, \lambda_n$ such that

$$\int_a^b \rho(x)\, d\alpha(x) = \lambda_1 \rho(x_1) + \lambda_2 \rho(x_2) + \ldots + \lambda_n \rho(x_n),$$

for an arbitrary POLYNOMIAL of order $2n-1$ and the $\lambda_n's$ are called CHRISTOFFEL NUMBERS. The distribution $d\alpha(x)$ and the INTEGER n uniquely determine these numbers λ_ν.

Gauss-Jordan Elimination

A method for finding a MATRIX INVERSE. To apply Gauss-Jordan elimination, operate on a MATRIX

$$[\mathsf{A} \quad \mathsf{I}] \equiv \begin{bmatrix} a_{11} & \cdots & a_{1n} & 1 & 0 & \cdots & 0 \\ a_{21} & \cdots & a_{2n} & 0 & 1 & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} & 0 & 0 & \cdots & 1 \end{bmatrix},$$

where I is the IDENTITY MATRIX, to obtain a MATRIX OF THE FORM

$$\begin{bmatrix} 1 & 0 & \cdots & 0 & b_{11} & \cdots & b_{1n} \\ 0 & 1 & \cdots & 0 & b_{21} & \cdots & b_{2n} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 & b_{n1} & \cdots & b_{nn} \end{bmatrix}.$$

The MATRIX

$$\mathsf{B} \equiv \begin{bmatrix} b_{11} & \cdots & b_{1n} \\ b_{21} & \cdots & b_{2n} \\ \vdots & \ddots & \vdots \\ b_{n1} & \cdots & b_{nn} \end{bmatrix}$$

is then the MATRIX INVERSE of A. The procedure is numerically unstable unless PIVOTING (exchanging rows and columns as appropriate) is used. Picking the largest available element as the pivot is usually a good choice.

Gauss-Kronrod Quadrature

An adaptive GAUSSIAN QUADRATURE method for numerical integration in which error is estimation based on evaluation at special points known as "Kronrod points." By suitably picking these points, abscissas from previous iterations can be reused as part of the new set of points, whereas usual GAUSSIAN QUADRATURE would require recomputation of all abscissas at each iteration. This is particularly important when some specified degree of accuracy is needed but the number of points needed to achieve this accuracy is not known ahead of time. Kronrod (1964) showed how to pick Kronrod points optimally from Gauss-Legendre quadrature, and Patterson (1968, 1969) showed how to compute continued extensions of this kind (Press *et al.* 1992, p. 154).

With `Method->Automatic`, the *Mathematica* `NIntegrate` command uses Gauss-Kronrod quadrature for 1-D integrals.

Gauss-Kummer Series

$$ {}_2F_1(-\tfrac{1}{2}, -\tfrac{1}{2}; 1; h^2) = \sum_{n=0}^{\infty} \binom{\frac{1}{2}}{n}^2 h^{2n} = 1 + \tfrac{1}{4}h^2 + \tfrac{1}{64}h^4 + \tfrac{1}{256}h^6 + \ldots $$

(Sloane's A056981 and A056982), where ${}_2F_1(a, b; c; x)$ is a HYPERGEOMETRIC FUNCTION. This can be derived using KUMMER'S QUADRATIC TRANSFORMATION. The Gauss-Kummer series is closely related to the PERIMETER of an ellipse.

Gauss-Kuzmin-Wirsing Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let x_0 be a random number from [0, 1] written as a simple CONTINUED FRACTION

$$ x_0 = 0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \ldots}}}. \quad (1) $$

Define the SHIFT TRANSFORMATION by

$$ x_n = 0 + \cfrac{1}{a_{n+1} + \cfrac{1}{a_{n+2} + \cfrac{1}{a_{n+3} + \ldots}}}. \quad (2) $$

$$ = \frac{1}{x_{n-1}} - \left\lfloor \frac{1}{x_{n-1}} \right\rfloor, \quad (3) $$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. In a letter to Laplace dated January 30, 1812, Gauss said that he could prove by a simple argument that if $F(n, x)$ is the probability that $x_n < x$, then

$$ \lim_{n\to\infty} F(n, x) = \frac{\ln(1+x)}{\ln 2} \quad (4) $$

(Rockett and Szüsz 1992, pp. 151–52).

However, Gauss was unable to describe the behavior of the correction term in

$$ F(n, x) = \frac{\ln(1+x)}{\ln 2} + \epsilon(n). \quad (5) $$

Kuzmin (1928) published the first analysis of the asymptotic behavior of $F(n, x)$, obtaining

$$ F(n, x) = \frac{\ln(1+x)}{\ln 2} + \mathcal{O}(q^{\sqrt{n}}) \quad (6) $$

with $0 < q < 1$. Using a different method, Lévy (1929) obtained

$$ F(n, x) = \frac{\ln(1+x)}{\ln 2} + \mathcal{O}(q^n) \quad (7) $$

with $q = 0.7$. Wirsing (1974) subsequently showed, among other results, that

$$ \lim_{n\to\infty} \frac{F(n, x) - \dfrac{\ln(1+x)}{\ln 2}}{(-\lambda)^n} = \Psi(x), \quad (8) $$

where $\lambda = 0.3036630029\ldots$ and $\Psi(x)$ is an analytic function with $\Psi(0) = \Psi(1) = 0$. This constant is connected to the efficiency of the EUCLIDEAN ALGORITHM (Knuth 1981).

Gear Curve

A curve resembling a gear with n teeth given by the PARAMETRIC EQUATIONS

$$x = r \cos t$$

$$y = r \sin t,$$

where

$$r = a + \frac{1}{b} \tanh[b \sin(nt)].$$

The above curve has $n = 12$, $a = 1$, and $b = 10$.

Gear Graph

A WHEEL GRAPH with a VERTEX added between each pair of adjacent VERTICES.

Gegenbauer Differential Equation

The second-order ORDINARY DIFFERENTIAL EQUATION

$$(1-x^2)y'' - 2(\mu+1)xy' + (\nu-\mu)(\nu+\mu+1)y = 0 \quad (1)$$

sometimes called the hyperspherical differential equation (Iyanaga and Kawada 1980, p. 1480; Zwillinger 1997, p. 123). The solution to this equation is

$$y = (x^2-1)^{-\mu/2}[C_1 P_\nu^\mu(x) + C_2 Q_\nu^\mu(x)], \quad (2)$$

where $P_\nu^\mu(x)$ is an associated LEGENDRE FUNCTION OF THE FIRST KIND and $Q_\nu^\mu(x)$ is an associated LEGENDRE FUNCTION OF THE SECOND KIND.

A number of other forms of this equation are sometimes also known as the ultraspherical or Gegenbauer differential equation, including

$$(1-x^2)y'' - (2\mu+1)xy' + \nu(\nu+2\mu)y = 0. \quad (3)$$

The general solutions to this equation are

$$y = (x^2-1)^{(1-2\mu)/4} \times [C_1 P^{1/2-\mu}_{-1/2+\mu+\nu}(x) + C_2 Q^{1/2-\mu}_{-1/2+\mu+\nu}(x)]. \quad (4)$$

However, if μ is an integer, then the second part of this equation no longer provides a solution, and the solutions are known as the GEGENBAUER POLYNOMIALS $C_\nu^{(\mu)}(x)$, also known as ultraspherical polynomials (possibly depending on normalization).

The form

$$(1-x^2)y'' - (2m+3)xy' + \lambda y = 0 \quad (5)$$

is also given by Infeld and Hull (1951, pp. 21–8) and Zwillinger (1997, p. 122). It has the solution

$$y = (x^2-1)^{-(2m+1)/4} \times \left[C_1 P^{1/2+m}_{-1/2+\sqrt{(1+m)^2+\lambda}}(x) + C_2 Q^{1/2+m}_{-1/2+\sqrt{(1+m)^2+\lambda}}(x)\right]. \quad (6)$$

Gegenbauer Function

GEGENBAUER POLYNOMIAL

Gegenbauer Polynomial

The Gegenbauer polynomials $C_n^{(\lambda)}(x)$ are solutions to the GEGENBAUER DIFFERENTIAL EQUATION for INTEGER n and $\lambda < 1/2$. They are generalizations of the associated LEGENDRE POLYNOMIALS to $(n+2)$-D space, and are proportional to (or, depending on the

normalization, equal to) the ultraspherical polynomials $P_n^{(\lambda)}(x)$.

Following Szego, in this work, Gegenbauer polynomials are given in terms of the JACOBI POLYNOMIALS $P_n^{(\alpha,\beta)}(x)$ with $\alpha=\beta=\lambda-1/2$ by

$$C_n^{(\lambda)}(x)=\frac{\Gamma(\lambda+\frac{1}{2})}{\Gamma(2\lambda)}\frac{\Gamma(n+2\lambda)}{\Gamma(n+\lambda+\frac{1}{2})}P_n^{(\lambda-1/2,\,\lambda-1/2)}(x) \quad (1)$$

(Szego 1975, p. 80), thus making them equivalent to the Gegenbauer polynomials implemented in *Mathematica* as GegenbauerC[n, $lambda$, x]. These polynomials are also given by the GENERATING FUNCTION

$$\frac{1}{(1-2xt+t^2)^\lambda}=\sum_{n=0}^\infty C_n^{(\lambda)}(x)t^n. \quad (2)$$

The first few Gegenbauer polynomials are

$$C_0^{(\lambda)}(x)=1 \quad (3)$$

$$C_1^{(\lambda)}(x)=2\lambda x \quad (4)$$

$$C_2^{(\lambda)}(x)=-\lambda+2\lambda(1+\lambda)x^2 \quad (5)$$

$$C_3^{(\lambda)}(x)=-2\lambda(1+\lambda)x+\tfrac{4}{3}\lambda(1+\lambda)(2+\lambda)x^3. \quad (6)$$

In terms of the HYPERGEOMETRIC FUNCTIONS,

$$C_n^{(\lambda)}(x)=\binom{n+2\lambda-1}{n}\times{}_2F_1(-n,\ n+2\lambda;\ \lambda+\tfrac{1}{2};\ \tfrac{1}{2}(1-x)) \quad (7)$$

$$=2^n\binom{n+\lambda-1}{n}(x-1)^n{}_2F_1\times\left(-n,\ -n-\lambda+\tfrac{1}{2};\ -2n-2\lambda+1;\ \frac{2}{1-x}\right) \quad (8)$$

$$=\binom{n+2\lambda+1}{n}\left(\frac{x+1}{2}\right)^n{}_2F_1\times\left(-n,\ -n-\lambda+\tfrac{1}{2};\ \lambda+\tfrac{1}{2};\ \frac{x-1}{x+1}\right). \quad (9)$$

They are normalized by

$$\int_{-1}^1(1-x^2)^{\lambda-1/2}[C_n^{(\lambda)}]^2\,dx=2^{1-2\lambda}\pi\frac{\Gamma(n+2\lambda)}{(n+\lambda)\Gamma^2(\lambda)\Gamma(n+1)}. \quad (10)$$

Derivative identities include

$$\frac{d}{dx}C_n^{(\lambda)}(x)=2\lambda C_{n-1}^{(\lambda+1)}(x) \quad (11)$$

$$(1-x^2)\frac{d}{dx}[C_n^{(\lambda)}]=[2(n+\lambda)]^{-1}[(n+2\lambda-1)\times(n+2\lambda)C_{n-1}^{(\lambda)}(x)-n(n+1)C_{n+1}^{(\lambda)}(x)] \quad (12)$$

$$=-nxC_n^{(\lambda)}(x)+(n+2\lambda-1)C_{n-1}^{(\lambda)}(x) \quad (13)$$

$$=(n+2\lambda)xC_n^{(\lambda)}(x)-(n+1)C_{n+1}^{(\lambda)}(x) \quad (14)$$

$$nC_n^{(\lambda)}(x)=x\frac{d}{dx}[C_n^{(\lambda)}(x)]-\frac{d}{dx}[C_{n-1}^{(\lambda)}(x)] \quad (15)$$

$$(n+2\lambda)C_n^{(\lambda)}(x)=\frac{d}{dx}[C_{n+1}^{(\lambda)}(x)]-x\frac{d}{dx}[C_n^{(\lambda)}(x)] \quad (16)$$

$$\frac{d}{dx}[C_{n+1}^{(\lambda)}(x)-C_{n-1}^{(\lambda)}(x)]=2(n+\lambda)C_n^{(\lambda)}C_n^{(\lambda)}(x) \quad (17)$$

$$=2\lambda[C_n^{(\lambda+1)}(x)-C_{n-2}^{(\lambda+1)}(x)] \quad (18)$$

(Szego 1975, pp. 80–3).

A RECURRENCE RELATION is

$$nC_n^{(\lambda)}(x)=2(n+\lambda-1)xC_{n-1}^{(\lambda)}(x)-(n+2\lambda-2)C_{n-2}^{(\lambda)}(x) \quad (19)$$

for $n=2, 3, \ldots$.

Special double-ν FORMULAS also exist

$$C_{2\nu}^{(\lambda)}(x)=\binom{2\nu+2\lambda-1}{2\nu}{}_2F_1(-\nu,\nu+\lambda;\ \lambda+\tfrac{1}{2};\ 1-x^2) \quad (20)$$

$$=(-1)^\nu\binom{\nu+\lambda-1}{\nu}{}_2F_1(-\nu,\ \nu+\lambda;\ \tfrac{1}{2};\ x^2) \quad (21)$$

$$C_{2\nu+1}^{(\lambda)}(x)=\binom{2\nu+2\lambda}{2\nu+1}x\,{}_2F_1(-\nu,\nu+\lambda+1;\lambda+\tfrac{1}{2};1-x^2) \quad (22)$$

$$=(-1)^\nu 2\lambda\binom{\nu+\lambda}{\nu}x\,{}_2F_1(-\nu,\ \nu+\lambda+1;\ \tfrac{3}{2};\ x^2). \quad (23)$$

Koschmieder (1920) gives representations in terms of ELLIPTIC FUNCTIONS for $\lambda=-3/4$ and $\lambda=-2/3$.

Gelfand Transform

The Gelfand transform $x \mapsto \hat{x}$ is defined as follows. If $\phi : B \to \mathbb{C}$ is linear and multiplicative in the senses

$$\phi(ax+by) = a\phi(x) + b\phi(y)$$

and

$$\phi(xy) = \phi(x)\phi(y),$$

where B is a commutative BANACH ALGEBRA, then write $\hat{x}(\phi) = \phi(x)$. The Gelfand transform is automatically bounded.

For example, if $B = L^1(\mathbb{R})$ with the usual norm, then B is a BANACH ALGEBRA under convolution and the Gelfand transform is the FOURIER TRANSFORM. (In fact, $\mathbb{R}$ may be replaced by any locally compact Abelian group, and then B has a unit if and only if the group is discrete.)

Gelfond's Theorem

Also called the Gelfond-Schneider theorem, Gelfond's theorem states that a^b is TRANSCENDENTAL if

1. a is ALGEBRAIC $\neq 0$, 1 and
2. b is ALGEBRAIC and IRRATIONAL.

This provides a partial solution to the seventh of HILBERT'S PROBLEMS. Gelfond's theorem is implied by SCHANUEL'S CONJECTURE (Chow 1999).

General Position

An arrangement of points with no three COLLINEAR, or of lines with no three CONCURRENT.

See also CONCURRENT, ORDINARY LINE, NEAR-PENCIL

References

Guy, R. K. "Unsolved Problems Come of Age." *Amer. Math. Monthly* **96**, 903–09, 1989.

General Prismatoid

A solid such that the AREA A_y of any section parallel to and a distance y from a fixed PLANE can be expressed as

$$A_y = ay^3 + by^2 + cy + d.$$

The volume of such a solid is the same as for a PRISMATOID,

$$V = \tfrac{1}{6} h(A_1 + 4M + A_2).$$

Examples include the CONE, CONICAL FRUSTUM, CYLINDER, PRISMATOID, PYRAMIDAL FRUSTUM, SPHERE, SPHERICAL SEGMENT, and SPHEROID.

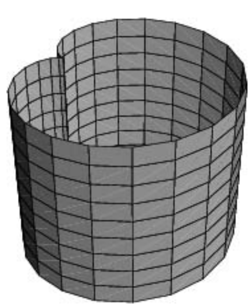
Mendelson, E. *Introduction to Mathematical Logic, 4th ed.* London: Chapman & Hall, p. 121, 1997.

Generalized Cone



A RULED SURFACE is called a generalized cone if it can be parameterized by $\mathbf{x}(u, v) = \mathbf{p} + v\mathbf{y}(u)$, where $\mathbf{p}$ is a fixed point which can be regarded as the vertex of the cone. A generalized cone is a REGULAR SURFACE wherever $v\mathbf{y} \times \mathbf{y}' \neq \mathit{0}$. The above surface is a generalized cone over a CARDIOID. A generalized cone is a FLAT SURFACE, and is sometimes called "conical surface."

See also CONE

Generalized Euclidean Algorithm

INTEGER RELATION

Generalized Fermat Equation

A generalization of the equation whose solution is desired in FERMAT'S LAST THEOREM

$$x^n + y^n = z^n$$

to

$$x^n + y^n = cz^n$$

for x, y, z, and c positive constants, with trivial solutions having $x = 0$, $y = 0$, or $z = 0$ being excluded. $n = 1$ is trivial to solve by taking $x = y = c$ and $z = 2$. $n = 2$ is more difficult, but can be solved by noting that solutions exist for values of c which can be written as a sum of two SQUARES, the first few of which are 1, 2, 4, 5, 8, 9, 10, 13, 16, 17, 18, 20, 25, 26, ... (Sloane's A001481).

Generalized Fibonacci Number

A generalization of the FIBONACCI NUMBERS defined by $1 = G_1 = G_2 = \ldots = G_{c-1}$ and the RECURRENCE RELATION

$$G_n = G_{n-1} + G_{n-c}. \tag{1}$$

These are the sums of elements on successive diagonals of a left-justified PASCAL'S TRIANGLE beginning in the left-most column and moving in steps of $c-1$ up and 1 right. The case $c = 2$ equals the usual FIBONACCI NUMBER. These numbers satisfy the identities

$$G_1 + G_2 + G_3 + \ldots + G_n = G_{n+3} - 1 \tag{2}$$

$$G_3 + G_6 + G_9 + \ldots + G_{3k} = G_{3k+1} - 1 \tag{3}$$

$$G_1 + G_4 + G_7 + \ldots + G_{3k+1} = G_{3k+2} \tag{4}$$

$$G_2 + G_5 + G_8 + \ldots + G_{3k+2} = G_{3k+3} \tag{5}$$

(Bicknell-Johnson and Spears 1996). For the special case $c = 3$,

$$G_{n+w} = G_{w-2}G_n + G_{w-3}G_{n+1} + G_{w-1}G_{n+2}. \tag{6}$$

Bicknell-Johnson and Spears (1996) give many further identities.

Horadam (1965) defined the generalized Fibonacci numbers $\{w_n\}$ as $w_n = w_n(a,\ b;\ p,\ q)$, where a, b, p, and q are INTEGERS, $w_0 = a$, $w_1 = b$, and $w_n = pw_{n-1} - qw_{n-2}$ for $n \geq 2$. They satisfy the identities

$$w_n w_{n+2r} - eq^n U_r = w_{n+r}^2 \tag{7}$$

$$4w_n w_{n+1}^2 w_{n+2} + (wq^n)^2 = (w_n w_{n+2} + w_{n+1}^2)^2 \tag{8}$$

$$w_n w_{n+1} w_{n+3} w_{n+4} = w_{n+2}^4 + eq^n(p^2+q)w_{n+2}^2 + e^2q^{2n+1}p^2 \tag{9}$$

$$4w_n w_{n+1} w_{n+2} w_{n+4} w_{n+5} w_{n+6} + e^2q^{2n}(w_n U_4 U_5 - w_{n+1} U_2 U_6 - w_n U_1 U_8)^2 = (w_{n+1} w_{n+2} w_{n+6} + w_n w_{n+4} w_{n+5})^2, \tag{10}$$

where

$$e \equiv pab - qa^2 - b^2 \tag{11}$$

$$U_n \equiv w_n(0,\ 1;\ p,\ q) \tag{12}$$

(Dujella 1996). The final above result is due to Morgado (1987) and is called the MORGADO IDENTITY.

Another generalization of the Fibonacci numbers is denoted x_n. Given x_1 and x_2, define the generalized Fibonacci number by $x_n \equiv x_{n-2} + x_{n-1}$ for $n \geq 3$,

$$\sum_{i=1}^{n} x_n = x_{n+2} - x_2 \tag{13}$$

$$\sum_{i=1}^{10} x_n = 11x_7 \tag{14}$$

$$x_n^2 - x_{n-1}x_{n+2} = (-1)^n(x_2^2 - x_1^2 - x_1x_2), \tag{15}$$

where the plus and minus signs alternate.

Generalized Helix

The GEODESICS on a general cylinder generated by lines PARALLEL to a line l with which the TANGENT makes a constant ANGLE.

See also HELIX

Generalized Hyperbolic Functions

In 1757, V. Riccati first recorded the generalizations of the HYPERBOLIC FUNCTIONS defined by

$$F_{n,r}^{\alpha}(x) \equiv \sum_{k=0}^{\infty} \frac{\alpha^k}{(nk+r)!} x^{nk+r}, \tag{1}$$

for $r = 0, ..., n-1$, where α is COMPLEX, with the value at $x = 0$ defined by

$$F_{n,0}^{\alpha}(0) = 1. \tag{2}$$

This is called the α-hyperbolic function of order n of the rth kind. The functions $F_{n,r}^{\alpha}$ satisfy

$$f^{(k)}(x) = \alpha f(x), \tag{3}$$

where

$$f^{(k)}(0) = \begin{cases} 0 & k \neq r,\ 0 \leq k \leq n-1, \\ 1 & k = r. \end{cases} \tag{4}$$

In addition,

$$\frac{d}{dx} F_{n,\,r}^{\alpha}(x) = \begin{cases} F_{n,r-1}^{\alpha}(x) & \text{for } 0 < r \leq n-1 \\ \alpha F_{n,n-1}^{\alpha}(x) & \text{for } r = 0. \end{cases} \tag{5}$$

The functions give a generalized EULER FORMULA

$$e^{\sqrt{\alpha}} = \sum_{r=0}^{n-1} (\sqrt{\alpha})^r F_{n,\,r}^{\alpha}(x). \tag{6}$$

Since there are n nth roots of α, this gives a system of n linear equations. Solving for $F_{n,\,r}^{\alpha}$ gives

$$F_{n,\,r}^{\alpha}(x) = \frac{1}{n}(\sqrt{\alpha})^{-r} \sum_{k=0}^{n-1} \omega_n^{-rk} \exp(\omega_n^k \sqrt{\alpha} x), \tag{7}$$

where

$$\omega_n = \exp\left(\frac{2\pi i}{n}\right) \tag{8}$$

is a PRIMITIVE ROOT OF UNITY.

The LAPLACE TRANSFORM is

$$\int_0^{\infty} e^{-st} F_{n,r}^{\alpha}(at)\, dt = \frac{s^{n-r-1} a^r}{s^n + \alpha a_n}. \tag{9}$$

The generalized hyperbolic function is also related to the MITTAG-LEFFLER FUNCTION $E_{\gamma}(x)$ by

$$F_{n,0}^{1}(x) = E_n(x^n). \tag{10}$$

The values $n = 1$ and $n = 2$ give the exponential and circular/hyperbolic functions (depending on the sign of α), respectively.

$$F_{1,0}^{\alpha}(x) = e^{\alpha x} \tag{11}$$

$$F_{2,0}^{\alpha}(x) = \cosh(\sqrt{\alpha} x) \tag{12}$$

$$F_{2,1}^{\alpha}(x) = \frac{\sinh(\sqrt{\alpha} x)}{\sqrt{\alpha}}. \tag{13}$$

For $\alpha = 1$, the first few functions are

$$F_{1,0}^{1}(x) = e^x$$

$$F_{2,0}^{1}(x) = \cosh x$$

$$F_{2,1}^{1}(x) = \sinh x$$

$$F_{3,0}^{1}(x) = \tfrac{1}{3}[e^x + 2e^{-x/2} \cos(\tfrac{1}{2}\sqrt{3}x)]$$

$$F_{3,1}^{1}(x) = \tfrac{1}{3}\left[e^x + 2e^{-x/2} \cos\left(\tfrac{1}{2}\sqrt{3}x + \tfrac{1}{3}\pi\right)\right]$$

$$F_{3,2}^{1}(x) = \tfrac{1}{3}\left[e^x + 2e^{-x/2} \cos\left(\tfrac{1}{2}\sqrt{3}x - \tfrac{1}{3}\pi\right)\right]$$

$$F_{4,0}^{1}(x) = \tfrac{1}{2}(\cosh x + \cos x)$$

$$F_{4,1}^{1}(x) = \tfrac{1}{2}(\sinh x + \sin x)$$

$$F_{4,2}^{1}(x) = \tfrac{1}{2}(\cosh x - \cos x)$$

$$F_{4,3}^{1}(x) = \tfrac{1}{2}(\sinh x + \sin x).$$

Generalized Hypergeometric Function

The generalized hypergeometric function is given by a HYPERGEOMETRIC SERIES, i.e., a series for which the ratio of successive terms can be written

$$\frac{a_{k+1}}{a_k}=\frac{P(k)}{Q(k)}=\frac{(k+a_1)(k+a_2)\cdots(k+a_p)}{(k+b_1)(k+b_2)\cdots(k+b_q)(k+1)}\,x. \tag{1}$$

(The factor of $k+1$ in the DENOMINATOR is present for historical reasons of notation.) The resulting generalized hypergeometric function is written

$$\sum_{k+0} a_k x^k = {}_pF_q\left[\begin{matrix}a_1, a_2, \ldots, a_p\\ b_1, b_2, \ldots, b_q\end{matrix};\ x\right] \tag{2}$$

$$=\sum_{k=0}^{\infty}\frac{(a_1)_k(a_2)_k\cdots(a_p)_k}{(b_1)_k b(b_2)_k\cdots(b_q)_k}\frac{x^k}{k!}, \tag{3}$$

where $(a)_k$ is the POCHHAMMER SYMBOL or RISING FACTORIAL

$$(a)_k\equiv\frac{\Gamma(a+k)}{\Gamma(a)}=a(a+1)\cdots(a+k-1). \tag{4}$$

This notation was introduced by Barnes (1907) (Hardy 1999, p. 111). If the argument $x=1$, then the function is abbreviated

$${}_pF_q\left[\begin{matrix}a_1, a_2, \ldots, a_p\\ b_1, b_2, \ldots, b_q\end{matrix}\right]\equiv{}_pF_q\left[\begin{matrix}a_1, a_2, \ldots, a_p\\ b_1, b_2, \ldots, b_q\end{matrix};\ x\right]. \tag{5}$$

The KAMPE DE FERIET FUNCTION is a generalization of the generalized hypergeometric function to two variables.

The generalized hypergeometric function $F_n(x)={}_pF_q\left[\begin{smallmatrix}a_1, a_2, \ldots, a_p\\ b_1, b_2, \ldots, b_q\end{smallmatrix};\ x\right]$ satisfies

$$\vartheta F_n(x)=n[F_{n+1}(x)-F_n(x)] \tag{6}$$

for any of its numerator parameters $n=\alpha_k$, and

$$\vartheta F_n(x)=(n-1)[F_{n-1}(x)-F_n(x)] \tag{7}$$

for any of its denominator parameters $n=\beta_k$, where

$$\vartheta = z\frac{d}{dz} \tag{8}$$

(Rainville 1971, Koepf 1998, p. 27).

${}_2F_1(a, b; c; z)$ is "the" HYPERGEOMETRIC FUNCTION, and ${}_1F_1(a; b; z)\equiv M(z)$ is the CONFLUENT HYPERGEOMETRIC FUNCTION. A function OF THE FORM ${}_0F_1(; b; z)$ is called a CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION.

The generalized hypergeometric function

$${}_{p+1}F_p\left[\begin{matrix}a_1, a_2, \ldots, a_{p+1}\\ b_1, b_2, \ldots, b_p\end{matrix};\ z\right] \tag{9}$$

is a solution to the DIFFERENTIAL EQUATION

$$[\vartheta(\vartheta+b-1)\cdots(\vartheta+b_p-1)-z(\vartheta+a_1)\times(\vartheta+a_2)\cdots(\vartheta+a_{p+1})]y=0. \tag{10}$$

The other linearly independent solution is

$$z^{1-b_1}\,{}_{p+1}F_p\times\left[\begin{matrix}1+a_1-b_1, 1-a_2-b_2, \ldots, 1+a_{p+1}-b_1\\ 2-b_1, 1-b_2-b_1, \ldots, 1-b_p-b_1\end{matrix};\ z\right]. \tag{11}$$

A generalized hypergeometric function ${}_{q+1}F_p$ converges absolutely on the unit circle if

$$\Re\left(\sum_{j=1}^{q}\beta_j-\sum_{j=1}^{q+1}\alpha_j\right)>0 \tag{12}$$

(Rainville 1971, Koepf 1998).

Many sums can be written as generalized hypergeometric functions by inspection of the ratios of consecutive terms in the generating HYPERGEOMETRIC SERIES. For example, for

$$f(n)\equiv\sum_k(-1)^k\binom{2n}{k}^2, \tag{13}$$

the ratio of successive terms is

$$\frac{a_{k+1}}{a_k}=\frac{(-1)^{k+1}\binom{2n}{k+1}^2}{(-1)^k\binom{2n}{k}^2}=-\frac{(k-2n)^2}{(k+1)^2}, \tag{14}$$

yielding

$$f(n)={}_2F_1\left[\begin{matrix}-2n, -2n\\ 1\end{matrix};\ -1\right]={}_2F_1(-2n, -2n; 1; -1) \tag{15}$$

(Petkovsek 1996, pp. 44–5).

Gosper (1978) discovered a slew of unusual hypergeometric function identities, many of which were subsequently proven by Gessel and Stanton (1982). An important generalization of Gosper's technique, called ZEILBERGER'S ALGORITHM, in turn led to the

powerful machinery of the WILF-ZEILBERGER PAIR (Zeilberger 1990).

Special hypergeometric identities include GAUSS'S HYPERGEOMETRIC THEOREM

$$ {}_2F_1(a,\ b,\ c;\ 1) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)} \tag{16}$$

for $\Re[c-a-b] > 0$, KUMMER'S FORMULA

$$ {}_2F_1(a,\ b,\ c;\ -1) = \frac{\Gamma(\frac{1}{2}b+1)\Gamma(b-a+1)}{\Gamma(b+1)\Gamma(\frac{1}{2}b-a+1)}, \tag{17}$$

where $a-b+c=1$ and b is a positive integer, SAALSCHÜTZ'S THEOREM

$$ {}_3F_2(a,\ b,\ c;\ d,\ e;\ 1) = \frac{(d-a)_{|c|}(d-b)_{|c|}}{(d)_{|c|}(d-a-b)_{|c|}} \tag{18}$$

for $d+e=a+b+c+1$ with c a negative integer and $(a)_n$ the POCHHAMMER SYMBOL, DIXON'S THEOREM

$$ {}_3F_2(a,\ b,\ c;\ d,\ e;\ 1) = \frac{(\frac{1}{2}a)!(a-b)!(a-c)!(\frac{1}{2}a-b-c)!}{a!(\frac{1}{2}a-b)!(\frac{1}{2}a-c)!(a-b-c)!}, \tag{19}$$

where $1+a/2-b-c$ has a positive REAL PART, $d=a-b+1$, and $e=a-c+1$, the CLAUSEN FORMULA

$$ {}_4F_3\left[\begin{matrix} a,\ b,\ c,\ d \\ e,\ f,\ g \end{matrix};\ 1\right] = \frac{(2a)_{|d|}(a+b)_{|d|}(2b)_{|d|}}{(2a+2b)_{|d|}a_{|d|}b_{|d|}}, \tag{20}$$

for $a+b+c-d=1/2$, $e=a+b+1/2$, $a+f=d+1=b+g$, d a nonpositive integer, and the DOUGALL-RAMANUJAN IDENTITY

$$ {}_7F_6\left[\begin{matrix} a_1,\ a_2,\ a_3,\ a_4,\ a_5,\ a_6,\ a_7, \\ b_1,\ b_2,\ b_3,\ b_4,\ b_5,\ b_6 \end{matrix};\ 1\right] = \frac{(a_1+1)_n(a_1-a_2-a_3+1)_n}{(a_1-a_2+1)_n(a_1-a_3+1)_n} \times \frac{(a_1-a_2-a_4+1)_n(a_1-a_3-a_4+1)}{(a_1-a_4+1)_n(a_1-a_2-a_3-a_4+1)_n}, \tag{21}$$

where $n=2a_1+1=a_2+a_3+a_4+a_5$, $a_6=1+a_1/2$, $a_7=-n$, and $b_i=1+a_1-a_{i+1}$ for $i = 1, 2, ..., 6$. For all these identities, $(a)_n$ is the POCHHAMMER SYMBOL.

Gessel (1994) found a slew of new identities using WILF-ZEILBERGER PAIRS, including the following:

$$ {}_5F_4\left[\begin{matrix} -a-b,\ n+1,\ n+c+1,\ 2n-a-b+1,\ n+\frac{1}{2}(3-a-b) \\ n-a-b-c+1,\ n-a-b+1,\ 2n+2,\ n+\frac{1}{2}(1-a-b) \end{matrix};1\right] = 0 \tag{22}$$

$$ {}_3F_2\left[\begin{matrix} -3n,\ \frac{2}{3}-c,\ 3n+2 \\ \frac{3}{2},\ 1-3c \end{matrix};\ \frac{3}{4}\right] = \frac{(c+\frac{2}{3})_n(\frac{1}{3})_n}{(1-c)_n(\frac{4}{3})_n} \tag{23}$$

$$ {}_3F_2\left[\begin{matrix} -3b,\ -\frac{3}{2}n,\ \frac{1}{2}(1-3n) \\ -3n,\ \frac{2}{3}-b-n \end{matrix};\ \frac{4}{3}\right] = \frac{(\frac{1}{3}-b)_n}{(\frac{1}{3}+b)_n} \tag{24}$$

$$ {}_4F_3\left[\begin{matrix} \frac{3}{2}+\frac{1}{5}n,\ \frac{2}{3},\ -n,\ 2n+2 \\ n+\frac{11}{6},\ \frac{4}{3},\ \frac{1}{5}n+\frac{1}{2} \end{matrix};\ \frac{2}{27}\right] = \frac{(\frac{5}{2})_n(\frac{11}{6})_n}{(\frac{3}{2})_n(\frac{7}{2})_n} \tag{25}$$

(Petkovsek *et al.* 1996, pp. 135–37).

The following table gives various named identities ordered by the orders $(p,\ q)$ of the ${}_pF_q$s they involve. Bailey (1935) gives a large number of such identities.

${}_2F_1$	GAUSS'S HYPERGEOMETRIC THEOREM, KUMMER'S THEOREM, ORR'S THEOREM, RAMANUJAN'S HYPERGEOMETRIC IDENTITY
${}_3F_2$	DARLING'S PRODUCTS, DIXON'S THEOREM, RAMANUJAN'S HYPERGEOMETRIC IDENTITY, SAALSCHÜTZ'S THEOREM, THOMAE'S THEOREM, WATSON'S THEOREM, WHIPPLE'S IDENTITY
${}_4F_3$	CLAUSEN FORMULA, WHIPPLE'S TRANSFORMATION
${}_5F_4$	DOUGALL'S THEOREM
${}_6F_5$	WHIPPLE'S IDENTITY
${}_7F_6$	DOUGALL-RAMANUJAN IDENTITY, WHIPPLE'S TRANSFORMATION
${}_9F_8$	BAILEY'S TRANSFORMATION

Nørlund (1955) gave the general transformation

$$ {}_nF_{n-1}\left[\begin{matrix} a_1,\ a_2,\ \ldots,\ a_n \\ b_1,\ b_2,\ \ldots,\ b_{n-1} \end{matrix};\ xz\right] = (1-z)^{-a_1}\sum_{\nu=0}^{\infty}\frac{(a_1)_\nu}{\nu!}\ {}_nF_n\left[\begin{matrix} -\nu,\ a_2,\ a_3,\ \ldots,\ a_n \\ b_1,\ b_2,\ \ldots,\ b_{n-1} \end{matrix};\ x\right] \times \left(\frac{z}{z-1}\right)^\nu, \tag{26}$$

where $(a)_n$ is the POCHHAMMER SYMBOL. This identity is based on the transformation due to Euler

$$ \sum_{n=0}^{\infty}\frac{(a)_n}{n!}a_nz^n = (1-z)^{-a}\sum_{n=0}^{\infty}\frac{(a)_n}{n!}\Delta^n a_0\left(\frac{z}{1-z}\right)^n, \tag{27}$$

where Δ is the FORWARD DIFFERENCE and

$$ \Delta^k a_0 = \sum_{m=0}^{k}(-1)^m\binom{k}{m}a_{k-m} \tag{28}$$

(Nørlund 1955).

Generalized Matrix Inverse

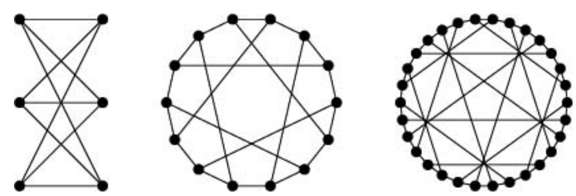
Moore-Penrose Generalized Matrix Inverse

Generalized Mean

A generalized version of the mean

$$m(t) \equiv \left(\frac{1}{n} \sum_{k=1}^{n} a_k^t \right)^{1/t} \tag{1}$$

with parameter t which gives the geometric mean, arithmetic mean, and harmonic mean as special cases:



$$\lim_{t \to 0} m(t) = G \tag{2}$$

$$m(1) = A \tag{3}$$

$$m(-1) = H. \tag{4}$$

See also Mean

Generalized Polygon

Let O be an incidence geometry, i.e., a set with a symmetric, reflexive binary relation I. Let e and f be elements of O. Let an incidence plane be an incidence geometry whose object set is the disjoint union of two sets P and L such that for $e, f \in P$ or $e, f \in L$, $(e, f) \in I$ only if $e=f$. Then a generalized polygon is an incidence plane such that for all $e, f \in O$,

1. There exists a chain of length at most n from e to f, and.
2. There exists at most one irreducible chain of length less than n from e to f.

(Feit and Higman 1964).

The only cubic generalized polygons are the generalized 2-gon $K_{3,3}$ (utility graph), generalized triangle $PG_{2,2}$ (Heawood graph), generalized quadrangle W_2 (the Levi graph), and generalized hexagon $GH_{2,2}$ (Feit and Higman 1964, Royle).

Generating Function

A POWER SERIES

$$f(x)=\sum_{n=0}^{\infty} a_n x^n \qquad (1)$$

whose COEFFICIENTS give the SEQUENCE $\{a_0, a_1, \ldots\}$. The *Mathematica* function `PowerSum` in the *Mathematica* add-on package `DiscreteMath'RSolve'` (which can be loaded with the command `<<DiscreteMath'`) gives the generating function of a given expression, and `ExponentialPowerSum` in the *Mathematica* add-on package `DiscreteMath'RSolve'` (which can be loaded with the command `<<DiscreteMath'`) gives the so-called EXPONENTIAL GENERATING FUNCTION. The generating function $f(x)$ is sometimes said to "ENUMERATE" a_n (Hardy 1999, p. 85).

Generating functions for the first few powers $a_n^{(p)}$ are given in the following table.

n^p	$f(x)$	series
1	$\frac{x}{1-x}$	$x+x^2+x^3+\ldots$
n	$\frac{x}{(1-x)^2}$	$x+2x^2+3x^3+4x^4+\ldots$
n^2	$\frac{x(x+1)}{(1-x)^3}$	$x+4x^2+9x^3+16x^4+\ldots$
n^3	$\frac{x(x^2+4x+1)}{(1-x)^4}$	$x+8x^2+27x^3+\ldots$
n^4	$\frac{x(x+1)(x^2+10x+1)}{(1-x)^5}$	$x+16x^2+81x^3+\ldots$

There are many beautiful generating functions for special functions in number theory. A few particularly nice examples are

$$f(x)=\frac{1}{\prod_{k=1}^{\infty} 1-x^k}=1+x+2x^2+3x^3+\ldots \qquad (2)$$

for the PARTITION FUNCTION P, and

$$f(x)=\sum_{n=0}^{\infty} F_n x^n=\frac{x}{1-x-x^2}$$

$$=x+x^2+2x^3+3x^4+\ldots \qquad (3)$$

for the FIBONACCI NUMBERS F_n.

The generating function of $G(t)$ of a sequence of numbers $f(n)$ given by the Z-TRANSFORM of $f(n)$ in the variable $1/t$ (Germundsson 2000).

Generation

In population studies, the direct offspring of a reference population (roughly) constitutes a single generation. For a CELLULAR AUTOMATON, the fundamental unit of time during which the rules of reproduction are applied once is called a generation.

Generator (Digitaddition)

An INTEGER used to generate a DIGITADDITION. A number can have more than one generator. If a number has no generator, it is called a SELF NUMBER.

Generator (Group)

A member of a CYCLIC GROUP, the POWERS of which generate the entire GROUP.

See also FINITELY GENERATED

Generic Character

For a form Q, the generic character $\chi_i(Q)$ OF THE FORM is defined as the values of $\chi_i(m)$ where $(m, 2d) = 1$ and Q represents m: $\chi_1(Q)$, $\chi_2(Q)$, ..., $\chi_r(Q)$ (Cohn 1980, p. 223). The characters apply to the class of properly equivalent forms as they represent the same numbers.

Genetic Algorithm

An adaptive STOCHASTIC OPTIMIZATION ALGORITHM involving search and optimization that was first used by John Holland. Holland created an electronic organism as a binary string ("chromosome"), and then used genetic and evolutionary principles of fitness-proportionate selection for reproduction (including random crossover and mutation) to search enormous solution spaces efficiently. So-called genetic programming languages apply the same principles, using an expression tree instead of a bit string as the "chromosome."

Genocchi Number

A number given by the GENERATING FUNCTION

$$\frac{2t}{e^t+1} = \sum_{n=1}^{\infty} G_n \frac{t^n}{n!}.$$

It satisfies $G_1 = 1$, $G_3 = G_5 = G_7 = \ldots = 0$, and even coefficients are given by

$$G_{2n} = 2(1-2^{2n})B_{2n} = 2nE_{2n-1}(0),$$

where B_n is a BERNOULLI NUMBER and $E_n(x)$ is an EULER POLYNOMIAL. The first few Genocchi numbers for n EVEN are -1, 1, -3, 17, -155, 2073, ... (Sloane's A001469).

Gentle Diagonal

PASCAL'S TRIANGLE

Gentle Giant Group

MONSTER GROUP

Genus (Curve)

One of the PLÜCKER CHARACTERISTICS, defined by

$$p \equiv \tfrac{1}{2}(n-1)(n-2) - (\delta+\kappa) = \tfrac{1}{2}(m-1)(m-2) - (\tau+\iota),$$

where m is the class, n the order, δ the number of nodes, κ the number of CUSPS, ι the number of stationary tangents (INFLECTION POINTS), and τ the number of BITANGENTS.

See also RIEMANN CURVE THEOREM

References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 100, 1959.

Genus (Form)

Consider the forms Q for which the GENERIC CHARACTERS $\chi_i(Q)$ are equal to some preassigned array of signs $e_i = 1$ or -1,

$$e_1, e_2, \ldots, e_r,$$

subject to $\prod_{i=1}^r e_i = 1$. There are 2^{r-1} possible arrays, where r is the number of distinct prime divisors of a field discriminant d, and the set of forms corresponding to each array is called a genus of forms. The forms for which all $e_i = 1$ are called the principal genus of forms, and each genus is also a collection of proper EQUIVALENCE CLASSES (Cohn 1980, pp. 223–24).

See also EQUIVALENCE CLASS, FUNDAMENTAL THEOREM OF GENERA, GENERIC CHARACTER

References

Cohn, H. "Compositions, Order, and Genera." Ch. 8 in *Advanced Number Theory.* New York: Dover, pp. 212–30, 1980.

Genus (Knot)

The least genus of any SEIFERT SURFACE for a given KNOT. The UNKNOT is the only KNOT with genus 0.

Genus (Surface)

A topologically invariant property of a surface defined as the largest number of nonintersecting simple closed curves that can be drawn on the surface without separating it. Roughly speaking, it is the number of HOLES in a surface. The genus of a surface, also called the geometric genus, is related to the EULER CHARACTERISTIC χ by

$$\chi = 2 - 2g.$$

See also EULER CHARACTERISTIC

Genus Theorem

The DIOPHANTINE EQUATION

$$x^2 + y^2 = p$$

can be solved for p a PRIME IFF $p \equiv 1 \pmod 4$ or $p = 2$. The representation is unique except for changes of sign or rearrangements of x and y. This theorem is intimately connected with the QUADRATIC RECIPROCITY THEOREM, and generalizes to the QUARTIC RECIPROCITY THEOREM.

See also COMPOSITION THEOREM, DIOPHANTINE EQUATION–4TH POWERS, FERMAT'S THEOREM, FUNDAMENTAL THEOREM OF GENERA, GENUS (FORM), QUADRATIC RECIPROCITY THEOREM

Geocentric Latitude

An AUXILIARY LATITUDE given by

$$\phi_g = \tan^{-1}\left[(1 - e^2)\right]\tan\phi].$$

The series expansion is

$$\phi_g = \phi - e_2 \sin(2\phi) + \tfrac{1}{2} e_2^2 \sin(4\phi) + \tfrac{1}{3} e_2^3 \sin(6\phi) + \ldots,$$

where

$$e_2 \equiv \frac{e^2}{2 - e^2}.$$

Geodesic

Given two points on a surface, the geodesic is defined as the shortest path on the surface connecting them. Geodesics also preserve a direction on a surface (Tietze 1965, pp. 26–7) and have many other interesting properties. The NORMAL VECTOR to any point of a GEODESIC arc lies along the normal to a surface at that point (Weinstock 1974, p. 65).

Furthermore, no matter how badly a SPHERE is distorted, there exist an infinite number of closed geodesics on it. This general result, demonstrated in the early 1990s, extended earlier work by Birkhoff, who proved in 1917 that there exists at least one closed geodesic on a distorted sphere, and Lyusternik and Schnirelmann, who proved in 1923 that there exist at least three closed geodesics on such a sphere (Cipra 1993, p. 28).

For a surface given parametrically by $x = x(u, v)$, $y = y(u, v)$, and $z = z(u, v)$, the geodesic can be found by minimizing the ARC LENGTH

$$L \equiv \int ds = \int \sqrt{dx^2 + dy^2 + dz^2}. \quad (1)$$

But

$$dx = \frac{\partial x}{\partial u}\, du + \frac{\partial x}{\partial v}\, dv \quad (2)$$

$$dx^2 = \left(\frac{\partial x}{\partial u}\right)^2 du^2 + 2\,\frac{\partial x}{\partial u}\,\frac{\partial x}{\partial v}\, du\, dv + \left(\frac{\partial x}{\partial v}\right)^2 dv^2, \quad (3)$$

and similarly for dy^2 and dz^2. Plugging in,

$$L=\int\left\{\left[\left(\frac{\partial x}{\partial u}\right)^2+\left(\frac{\partial y}{\partial u}\right)^2+\left(\frac{\partial z}{\partial u}\right)^2\right]du^2\right.$$
$$+2\left[\frac{\partial x}{\partial u}\frac{\partial x}{\partial v}+\frac{\partial y}{\partial u}\frac{\partial y}{\partial v}+\frac{\partial z}{\partial u}\frac{\partial z}{\partial v}\right]du\,dv$$
$$\left.+\left[\left(\frac{\partial x}{\partial v}\right)^2+\left(\frac{\partial y}{\partial v}\right)^2+\left(\frac{\partial z}{\partial v}\right)^2\right]dv^2\right\}^{1/2}. \quad (4)$$

This can be rewritten as

$$L=\int\sqrt{P+2Qv'+Rv'^2}\,du \quad (5)$$
$$=\int\sqrt{Pu'2+2Qu'+R}\,dv, \quad (6)$$

where

$$v'\equiv\frac{dv}{du} \quad (7)$$
$$u'\equiv\frac{du}{dv} \quad (8)$$

and

$$P\equiv\left(\frac{\partial x}{\partial u}\right)^2+\left(\frac{\partial y}{\partial u}\right)^2+\left(\frac{\partial z}{\partial u}\right)^2 \quad (9)$$
$$Q\equiv\frac{\partial x}{\partial u}\frac{\partial x}{\partial v}+\frac{\partial y}{\partial u}\frac{\partial y}{\partial v}+\frac{\partial z}{\partial u}\frac{\partial z}{\partial v} \quad (10)$$
$$R\equiv\left(\frac{\partial x}{\partial v}\right)^2+\left(\frac{\partial y}{\partial v}\right)^2+\left(\frac{\partial z}{\partial v}\right)^2. \quad (11)$$

Taking derivatives,

$$\frac{\partial L}{\partial v}=\tfrac{1}{2}(P+2Qv'+Rv'^2)^{-1/2}\left(\frac{\partial P}{\partial v}+2\frac{\partial Q}{\partial v}v'+\frac{\partial R}{\partial v}v'^2\right) \quad (12)$$
$$\frac{\partial L}{\partial v'}=\tfrac{1}{2}(P+2Qv'+Rv'^2)^{-1/2}(2Q+2Rv'), \quad (13)$$

so the EULER-LAGRANGE DIFFERENTIAL EQUATION then gives

$$\frac{\frac{\partial P}{\partial v}+2v'\frac{\partial Q}{\partial v}+v'^2\frac{\partial R}{\partial v}}{2\sqrt{P+2Qv'+Rv'^2}}-\frac{d}{du}\left(\frac{Q+Rv'}{\sqrt{P+2Qv'+Rv'^2}}\right)=0. \quad (14)$$

In the special case when P, Q, and R are explicit functions of u only,

$$\frac{Q+Rv'}{\sqrt{P+2Qv'+Rv'^2}}=c_1 \quad (15)$$
$$\frac{Q^2+2QRv'+R^2v'^2}{P+2Qv'+Rv'^2}=c_1^2 \quad (16)$$
$$v'^2R(R-c_1^2)+2v'Q(R-c_1^2)+(Q^2-Pc_1^2)=0 \quad (17)$$
$$v'=\frac{1}{2R(R-c_1^2)}\times\left[2Q(c_1^2-R)\pm\sqrt{4Q^2(R-c_1^2)-4R(R-c_1^2)(Q^2-Pc_1^2)}\right]. \quad (18)$$

Now, if P and R are explicit functions of u only *and* $Q=0$,

$$v'=\frac{\sqrt{4R(R-c_1^2)Pc_1^2}}{2R(R-c_1^2)}=c_1\sqrt{\frac{P}{R(R-c_1^2)}}, \quad (19)$$

so

$$v=c_1\int\sqrt{\frac{P}{R(R-c_1^2)}}\,du. \quad (20)$$

In the case $Q=0$ where P and R are explicit functions of v only, then

$$\frac{\frac{\partial P}{\partial v}+v'^2\frac{\partial R}{\partial v}}{2\sqrt{P+Rv'^2}}-\frac{d}{du}\left(\frac{Rv'}{\sqrt{P+Rv'^2}}\right)=0, \quad (21)$$

so

$$\frac{\partial P}{\partial v}+v'^2\frac{\partial R}{\partial v}-2\sqrt{P+Rv'^2}R\left[\frac{v''}{\sqrt{P+Rv'^2}}+\left(-\tfrac{1}{2}\right)\frac{v'(2Rv'v'')}{(P+Rv'^2)^{3/2}}\right]=0 \quad (22)$$
$$\frac{\partial P}{\partial v}+v'^2\frac{\partial R}{\partial v}-2Rv''+\frac{2R^2v'^2v''}{P+Rv'^2}=0 \quad (23)$$
$$\frac{Rv'^2}{\sqrt{P+Rv'^2}}-\sqrt{P+Rv'^2}=c_1 \quad (24)$$
$$Rv'^2-(P+Rv'^2)=c_1\sqrt{P+Rv'^2} \quad (25)$$
$$\left(\frac{p}{c_1}\right)^2=P+Rv'^2 \quad (26)$$
$$\frac{P^2-c_1^2P}{Rc_1^2}=v'^2, \quad (27)$$

and

$$u = c_1 \int \sqrt{\frac{R}{P^2 - c_1^2 P}}\, dv. \tag{28}$$

For a SURFACE OF REVOLUTION in which $y = g(x)$ is rotated about the x-AXIS so that the equation of the surface is

$$y^2 + z^2 = g^2(x), \tag{29}$$

the surface can be parameterized by

$$x = u \tag{30}$$

$$y = g(u) \cos v \tag{31}$$

$$z = g(u) \sin v. \tag{32}$$

The equation of the geodesics is then

$$v = c_1 \int \frac{\sqrt{1 + [g'(u)]^2}\, du}{g(u)\sqrt{[g(u)]^2 - c_1^2}}. \tag{33}$$

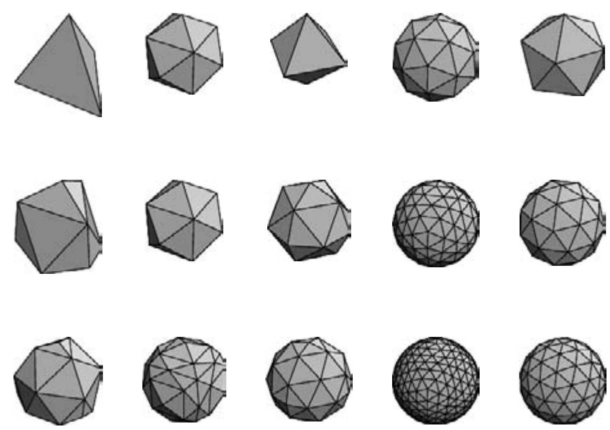
Geodesic Curvature

For a unit speed curve on a surface, the length of the surface-tangential component of acceleration is the geodesic curvature κ_g. Curves with $\kappa_g = 0$ are called GEODESICS. For a curve parameterized as $\boldsymbol{\alpha}(t) = \mathbf{x}(u(t), v(t))$, the geodesic curvature is given by

$$\kappa_g = \sqrt{EG - F^2}\,[-\Gamma_{11}^2 u'^3 + \Gamma_{22}^1 v'^3 - (2\Gamma_{12}^2 - \Gamma_{11}^1) u'^2 v' + (2\Gamma_{12}^1 - \Gamma_{22}^2) u' v'^2 + u'' v' - v'' u'],$$



where E, F, and G are coefficients of the first FUNDAMENTAL FORM and Γ_{ij}^k are CHRISTOFFEL SYMBOLS OF THE SECOND KIND.

Geodesic Dome

A TRIANGULATION of a PLATONIC SOLID or other POLYHEDRON to produce a close approximation to a SPHERE (or HEMISPHERE). The nth order geodesation operation replaces each polygon of the polyhedron by the projection onto the CIRCUMSPHERE of the order-n regular tessellation of that polygon. The above figure shows geodesations of orders 1 to 3 (from top to bottom) of the TETRAHEDRON, CUBE, OCTAHEDRON, DODECAHEDRON, and ICOSAHEDRON (from left to right), computed using `Geodesate[`*poly*, *n*`]` in the *Mathematica* add-on package `Graphics`Polyhedra`` (which can be loaded with the command `<<Graphics``).

R. Buckminster Fuller designed the first geodesic dome (i.e., geodesation of a HEMISPHERE). Fuller's dome was constructed from an ICOSAHEDRON by adding ISOSCELES TRIANGLES about each VERTEX and slightly repositioning the VERTICES. In such domes, neither the VERTICES nor the centers of faces necessarily lie at exactly the same distances from the center. However, these conditions are approximately satisfied.

In the geodesic domes discussed by Kniffen (1994), the sum of VERTEX angles is chosen to be a constant. Given a PLATONIC SOLID, let $e' \equiv 2e/v$ be the number of EDGES meeting at a VERTEX and n be the number of EDGES of the constituent POLYGON. Call the angle of the old VERTEX point A and the angle of the new VERTEX point F. Then

$$A = B \tag{1}$$

$$2e'A = nF \tag{2}$$

$$2A+F=180^\circ. \tag{3}$$

Solving for A gives

$$2A+\frac{2e'}{n}A=2A\left(1+\frac{e'}{n}\right)=180^\circ \tag{4}$$

$$A=90^\circ\frac{n}{e'+n}, \tag{5}$$

and

$$F=\frac{2e'}{n}A=180^\circ\frac{e'}{e'+n}. \tag{6}$$

The VERTEX sum is

$$\Sigma=nF=180^\circ\frac{e'n}{e'+n}. \tag{7}$$

Solid	f	v	e'	n	A	F	Σ
TETRAHEDRON			3	3	45°	90°	270°
CUBE	24	14	3	4	$51\frac{3}{7}^\circ$	$81\frac{3}{7}^\circ$	$308\frac{4}{7}^\circ$
OCTAHEDRON			4	3	$38\frac{4}{7}^\circ$	$108\frac{4}{7}^\circ$	$308\frac{4}{7}^\circ$
DODECAHEDRON	60	32	3	5	$56\frac{1}{4}^\circ$	$71\frac{1}{4}^\circ$	$337\frac{1}{2}^\circ$
ICOSAHEDRON			5	3	$33\frac{3}{4}^\circ$	$118\frac{3}{4}^\circ$	$337\frac{1}{2}^\circ$

Wenninger and Messer (1996) give general formulas for solving any geodesic chord factor and dihedral angle in a geodesic dome.

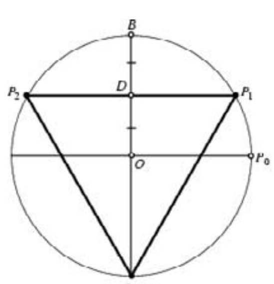
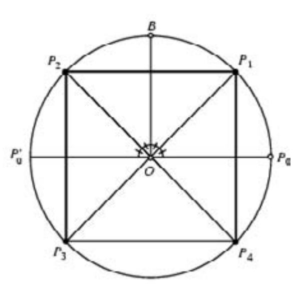
Geometric Construction

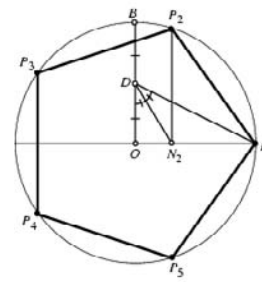


In antiquity, geometric constructions of figures and lengths were restricted to the use of only a straightedge and compass (or in Plato's case, a compass only; a so-called Mascheroni construction). Although the term "ruler" is sometimes used instead of "straightedge," no markings which could be used to make measurements were allowed according to the Greek prescription. Furthermore, the "compass" could not even be used to mark off distances by setting it and then "walking" it along, so the compass had to be considered to automatically collapse when not in the process of drawing a circle.

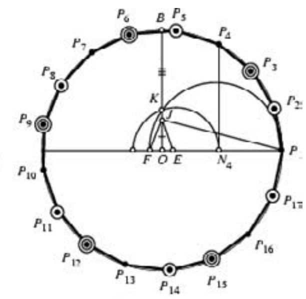
Because of the prominent place Greek geometric constructions held in Euclid's *Elements*, these constructions are sometimes also known as Euclidean constructions. Such constructions lay at the heart of the geometric problems of antiquity of circle squaring, cube duplication, and trisection of an angle. The Greeks were unable to solve these problems, but it was not until hundreds of years later that the problems were proved to be actually impossible under the limitations imposed.



Simple algebraic operations such as $a+b$, $a-b$, ra (for r a rational number), a/b, ab, and $\sqrt{x}$ can be performed using geometric constructions (bold 1982, Courant and Robbins 1996). Other more complicated constructions, such as the solution of Apollonius' problem and the construction of inverse points can also accomplished.



One of the simplest geometric constructions is the construction of a bisector of a line segment, illustrated above.



equilateral triangle construction

square construction

pentagon construction

17-gon construction

The Greeks were very adept at constructing polygons, but it took the genius of Gauss to mathematically determine which constructions were possible and which were not. As a result, Gauss determined that a series of polygons (the smallest of which has 17 sides; the heptadecagon) had constructions unknown to the Greeks. Gauss showed that the constructible polygons (several of which are illustrated above) were closely related to numbers called the Fermat primes.

Wernick (1982) gave a list of 139 sets of three located points from which a triangle was to be constructed. Of Wernick's original list of 139 problems, 20 had not yet been solved as of 1996 (Meyers 1996).

It is possible to construct rational numbers and Euclidean numbers using a straightedge and compass construction. In general, the term for a number which can be constructed using a compass and straightedge is a constructible number. Some irrational numbers, but *no* transcendental numbers, can be constructed.

It turns out that all constructions possible with a compass and straightedge can be done with a compass alone, as long as a line is considered constructed when its two endpoints are located. The reverse is also true, since Jacob Steiner showed that all constructions possible with straightedge and compass can be done using only a straightedge, as long as a fixed circle and its center (or two intersecting circles without their centers, or three nonintersecting circles) have been drawn beforehand. Such a construction is known as a Steiner construction.

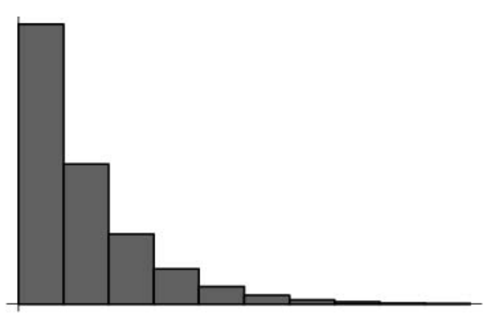
Geometrography is a quantitative measure of the simplicity of a geometric construction. It reduces geometric constructions to five types of operations, and seeks to reduce the total number of operations (called the "simplicity"rpar; needed to effect a geometric construction.

Dixon (1991, pp. 34–1) gives approximate constructions for some figures (the heptagon and nonagon) and lengths (pi) which cannot be rigorously constructed. Ramanujan (1913–4) and Olds (1963) give geometric constructions for $355/113 \approx \pi$. Gardner (1966, pp. 92–3) gives a geometric construction for

$$3+\frac{16}{113}=3.1415929\ldots\approx\pi.$$

Kochansky's approximate construction for π yields Kochansky's approximation

$$\sqrt{\frac{40}{3}-2\sqrt{3}}=3.141533\ldots\approx\pi$$



Steinhaus (1983, p. 143). Constructions for π are approximate (but inexact) forms of circle squaring.

Geometric Distribution

A discrete distribution for $n=1, 2, \ldots$ with probability function

$$P(n)=q^{n-1}P \quad (1)$$

$$=p(1-p)^{n-1}, \quad (2)$$

where $0<p<1$ and $(q\equiv 1-p)$. $P(n)$ is normalized, since

$$\sum_{n=1}^{\infty} P(n)=\sum_{n=1}^{\infty} q^{n-1}p=p\sum_{n=0}^{\infty} q^n=\frac{p}{1-q}=\frac{p}{p}=1 \quad (3)$$

The corresponding distribution function is

$$D(n)=\sum_{k=1}^{n} P(k)=1-q^n. \quad (4)$$

The MOMENT-GENERATING FUNCTION is given by

$$\phi(t) = p\left[1-(1-p)e^{it}\right]^{-1}, \tag{5}$$

or

$$M(t) = \langle e^{tn} \rangle = \sum_{n=1}^{\infty} e^{tn} p q^{n-1} = p \sum_{n=0}^{\infty} e^{t(n+1)} q^n$$

$$= pe^t \sum_{n=0}^{\infty} (e^t t)^n = \frac{pe^t}{1 - e^t q} \tag{6}$$

$$M'(t) = \frac{pe^t}{(1 - e^t q)^2} \tag{7}$$

$$M''(t) = \frac{pe^t(1 + qe^t)}{(1 - e^t q)^3} \tag{8}$$

$$M'''(t) = \frac{pe^t\left[1 + 4e^t(1-p) + e^{2t}(1-p)^2\right]}{(1 - e^t + e^t p)^4}. \tag{9}$$

Therefore, the RAW MOMENTS are

$$M'(0) = \mu_1' = \mu = \frac{p}{(1-q)^2} = \frac{p}{p^2} = \frac{1}{p} \tag{10}$$

$$M''(0) = \mu_2' = \frac{p(1+q)}{(1-q)^3} = \frac{p(2-p)}{p^3} = \frac{2-p}{p^2} \tag{11}$$

$$M'''(0) = \mu_3' = \frac{(6 - 6p + p^2)}{p^3} \tag{12}$$

$$M^4(0) = \mu_4' = \frac{(p-2)(-p^2 + 12p - 12)}{p^4}, \tag{13}$$

giving CENTRAL MOMENTS

$$\mu_2 = \frac{q}{p^2} \tag{14}$$

$$\mu_3 = \frac{(p-1)(p-2)}{p^3} \tag{15}$$

$$\mu_4 = \frac{(p-1)(-p^2 + 9p - 9)}{p^4}, \tag{16}$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are given by

$$\mu \equiv \mu_1' = \frac{1}{p} \tag{17}$$

$$\sigma^2 = \mu_2 = \frac{q}{p^2} \tag{18}$$

$$\gamma_1 = \frac{\mu_3}{\mu_2^{3/2}} = \frac{2-p}{\sqrt{q}} \tag{19}$$

$$\gamma_2 = \frac{\mu_4}{\mu_2^2} - 3 = \frac{p^2 - 6p + 6}{1-p}. \tag{20}$$

In fact, the moments of the distribution are given analytically in terms of the POLYLOGARITHM function,

$$\mu_k' \equiv \sum_{n=1}^{\infty} p(n) n^k = \sum_{n=1}^{\infty} p(1-p)^{n-1} n^k$$

$$= \frac{p\,\mathrm{Li}_{-k}(1-p)}{1-p}. \tag{21}$$

For the case $p = 1/2$ (corresponding to the distribution of the number of COIN TOSSES needed to win in the SAINT PETERSBURG PARADOX) the formula (21) gives

$$\mu_k'|_{p=1/2} = \mathrm{Li}_{-k}\left(\tfrac{1}{2}\right). \tag{22}$$

The first few raw moments are therefore 2, 6, 26, 150, 1082, ... (Sloane's A000629), which have EXPONENTIAL GENERATING FUNCTIONS $f(x) = -\ln(2 - e^x)$ and $g(x) = e^x/(2 - e^x)$. From (22), the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = 2 \tag{23}$$

$$\sigma^2 = 2 \tag{24}$$

$$\gamma_1 = \tfrac{3}{2}\sqrt{2} \tag{25}$$

$$\gamma_2 = \tfrac{13}{2}. \tag{26}$$

The first CUMULANT of the geometric distribution is

$$\kappa_1 = \frac{1-p}{p}, \tag{27}$$

and subsequent CUMULANTS are given by the RECURRENCE RELATION

$$\kappa_{r+1} = (1-p)\frac{d\kappa_r}{dp}. \tag{28}$$

Geometric Dual Graph

G G^*

Given a PLANAR GRAPH G, its geometric dual G^* is constructed by placing a vertex in each region of G (including the exterior region) and, if two regions have an edge x in common, joining the corresponding vertices by an edge X^* crossing only x. The result is always a planar PSEUDOGRAPH. However, an abstract graph with more than one embedding on the sphere can give rise to more than one dual.

Whitney showed that the geometric dual graph and COMBINATORIAL DUAL GRAPH are equivalent (Harary 1994, p. 115), and so may simply be called "the" DUAL GRAPH.

Geometric Mean

The geometric mean of a sequence $\{a_i\}_{i=1}^n$ is defined by

$$G(a_1,\ \ldots,\ a_n) \equiv \left(\prod_{i=1}^n a_i\right)^{1/n}. \tag{1}$$

Thus,

$$G(a_1,\ a_2) = \sqrt{a_1 a_2} \tag{2}$$

$$G(a_1,\ a_2,\ a_3) = (a_1 a_2 a_3)^{1/3}, \tag{3}$$

and so on.

Hoehn and Niven (1985) show that

$$G(a_1+c,\ a_2+c,\ \ldots,\ a_n+c) > c + G(a_1,\ a_2,\ \ldots,\ a_n) \tag{4}$$

for any POSITIVE constant c.

Geometric Problems of Antiquity

The Greek problems of antiquity were a set of geometric problems whose solution was sought using only COMPASS and STRAIGHTEDGE:

1. CIRCLE SQUARING.
2. CUBE DUPLICATION.
3. TRISECTION of an ANGLE.

Only in modern times, more than 2,000 years after they were formulated, were all three ancient problems proved insoluble using only COMPASS and STRAIGHTEDGE.

Another ancient geometric problem not proved impossible until 1997 is ALHAZEN'S BILLIARD PROBLEM. As Ogilvy (1990) points out, constructing the general REGULAR POLYHEDRON was really a "fourth" unsolved problem of antiquity.

Geometric Progression

GEOMETRIC SEQUENCE

Geometric Realization

If the ABSTRACT SIMPLICIAL COMPLEX S is isomorphic with the VERTEX SCHEME of the SIMPLICIAL COMPLEX K, then K is said to be a geometric realization of S, and is uniquely determined up to a linear isomorphism.

See also ABSTRACT SIMPLICIAL COMPLEX, VERTEX SCHEME

References

Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, 1993.

Geometric Sequence

A geometric sequence is a SEQUENCE $\{a_k\}$, $k = 1, 2, \ldots$, such that each term is given by a multiple r of the previous one. Another equivalent definition is that a sequence is geometric IFF it has a zero BIAS. If the multiplier is r, then the kth term is given by

$$a_k = r a_{k-1} = r^2 a_{k-2} = a_0 r^k.$$

Without loss of generality, take $a_0 = 1$, giving

$$a_k = r^k.$$

Geometric Series

A geometric series $\Sigma_k a_k$ is a series for which the ratio of each two consecutive terms a_{k+1}/a_k is a constant function of the summation index k. The more general case of the ratio a RATIONAL FUNCTION of the summation index k produces a series called a HYPERGEOMETRIC SERIES.

For the simplest case of the ratio $a_{k+1}/a_k = r$ equal to a constant r, the terms a_k are OF THE FORM $a_k = a_0 r^k$. Letting $a_0 = 1$, the GEOMETRIC SEQUENCE $\{a_k\}_{k=0}^n$ with constant $|r| < 1$ is given by

$$S_n = \sum_{k=0}^{n} a_k = \sum_{k=0}^{n} r^k \qquad (1)$$

is given by

$$S_n \equiv \sum_{k=0}^{n} r^k = 1 + r + r^2 + \ldots + r^n. \qquad (2)$$

Multiplying both sides by r gives

$$rS_n = r + r^2 + r^3 + \ldots + r^{n+1}, \qquad (3)$$

and subtracting (3) from (2) then gives

$$(1-r)S_n = (1 + r + r^2 + \ldots r^n) - (r + r^2 + r^3 + \ldots + r^{n+1}) = 1 - r^{n+1}, \qquad (4)$$

so

$$S_n \equiv \sum_{k=0}^{n} r^k = \frac{1 - r^{n+1}}{1 - r}. \qquad (5)$$

For $-1 < r < 1$, the sum converges as $n \to \infty$, in which case

$$S \equiv S_\infty = \sum_{k=0}^{\infty} r^k = \frac{1}{1 - r} \qquad (6)$$

Similarly, if the sums are taken starting at $k = 1$ instead of $k = 0$,

$$\sum_{k=1}^{n} r^k = \frac{r(1 - r^n)}{1 - r} \qquad (7)$$

$$\sum_{k=1}^{\infty} r^k = \frac{r}{1 - r}, \qquad (8)$$

the latter of which is valid for $|r| < 1$.

Geometrization Conjecture

THURSTON'S GEOMETRIZATION CONJECTURE

Geometrography

A quantitative measure of the simplicity of a GEOMETRIC CONSTRUCTION which reduces geometric constructions to five steps. It was devised by È. Lemoine.

S_1 Place a STRAIGHTEDGE's EDGE through a given POINT,
S_2 Draw a straight LINE,
C_1 Place a POINT of a COMPASS on a given POINT,
C_2 Place a POINT of a COMPASS on an indeterminate POINT on a LINE,
C_3 Draw a CIRCLE.

Geometrography seeks to reduce the number of operations (called the "SIMPLICITY"rpar; needed to effect a construction. If the number of the above operations are denoted m_1, m_2, n_1, n_2, and n_3, respectively, then the SIMPLICITY is $m_1 + m_2 + n_1 + n_2 + n_3$ and the symbol is $m_1S_1 + m_2S_2 + n_1C_1 + n_2C_2 + n_3C_3$. It is apparently an unsolved problem to determine if a given GEOMETRIC CONSTRUCTION is of the smallest possible simplicity.

Geometry

Geometry is the study of figures in a SPACE of a given number of dimensions and of a given type. The most common types of geometry are PLANE GEOMETRY (dealing with objects like the LINE, CIRCLE, TRIANGLE, and POLYGON), SOLID GEOMETRY (dealing with objects like the LINE, SPHERE, and POLYHEDRON), and SPHERICAL GEOMETRY (dealing with objects like the SPHERICAL TRIANGLE and SPHERICAL POLYGON). Geometry was part of the QUADRIVIUM taught in medieval universities.

Historically, the study of geometry proceeds from a small number of accepted truths (AXIOMS or POSTULATES), then builds up true statements using a systematic and rigorous step-by-step PROOF. However, there is much more to geometry than this relatively dry textbook approach, as evidenced by some of the beautiful and unexpected results of PROJECTIVE GEOMETRY (not to mention Schubert's powerful but questionable ENUMERATIVE GEOMETRY).

The late mathematician E. T. Bell has described geometry as follows (Coxeter and Greitzer 1967, p. 1): "With a literature much vaster than those of ALGEBRA and ARITHMETIC combined, and at least as extensive as that of ANALYSIS, geometry is a richer treasure house of more interesting and half-forgotten

things, which a hurried generation has no leisure to enjoy, than any other division of mathematics." While the literature of ALGEBRA, ARITHMETIC, and ANALYSIS has grown extensively since Bell's day, the remainder of his commentary holds even more so today.

Formally, a geometry is defined as a complete locally homogeneous RIEMANNIAN METRIC. In $\mathbb{R}^2$, the possible geometries are Euclidean planar, hyperbolic planar, and elliptic planar. In $\mathbb{R}^3$, the possible geometries include Euclidean, hyperbolic, and elliptic, but also include five other types.

Geometry of Position

PROJECTIVE GEOMETRY

Gergonne Line

The perspective line for the CONTACT TRIANGLE ΔDEF and its TANGENTIAL TRIANGLE ΔABC. It is determined by the NOBBS POINTS D', E', and F'.

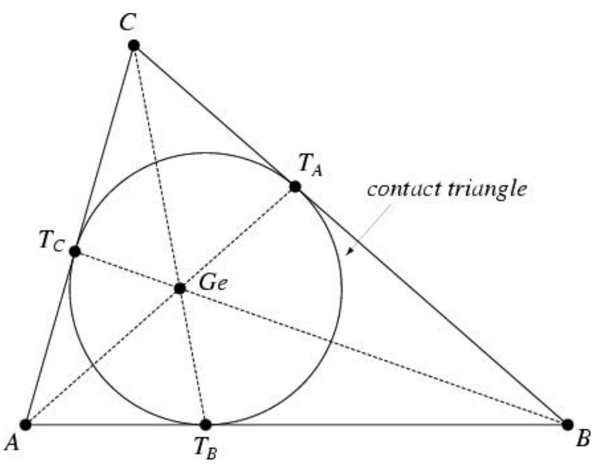
In addition to the NOBBS POINTS, the FLETCHER POINT and EVANS POINT also lie on the Gergonne line where it intersects the SODDY LINE and EULER LINE, respec-

tively. The D and D' coordinates are given by

$$D = B + \frac{f}{e} C$$

$$D' = B - \frac{f}{e} C,$$

so $BDCD'$ form a HARMONIC RANGE. The equation of the Gergonne line is



$$\frac{\alpha}{d} + \frac{\beta}{e} + \frac{\gamma}{f} = 0.$$

See also CONTACT TRIANGLE, EULER LINE, EVANS POINT, FLETCHER POINT, NOBBS POINTS, SODDY LINE, TANGENTIAL TRIANGLE

References

Gergonne Point

The common point Ge of the CONCURRENT lines from the CONTACT TRIANGLE TRIANGLE'S INCIRCLE to the opposite VERTICES. It has TRIANGLE CENTER FUNCTION

$$\alpha = [a(b + c - a)]^{-1} = \tfrac{1}{2} \sec^2 A.$$

The Gergonne point Ge is the ISOTOMIC CONJUGATE POINT of the NAGEL POINT Na. The CONTACT TRIANGLE and TANGENTIAL TRIANGLE are perspective from the Gergonne point, and the Gergonne point of a triangle is the SYMMEDIAN POINT of its CONTACT TRIANGLE (Honsberger 1995).

EIGHT CURVE

Gergorin Circle Theorem

Gives a region in the COMPLEX PLANE containing all the EIGENVALUES of a COMPLEX SQUARE MATRIX. Define

$$R_i = \sum_{\substack{i=1 \\ j \neq i}}^{n} |a_{i,j}|, \tag{1}$$

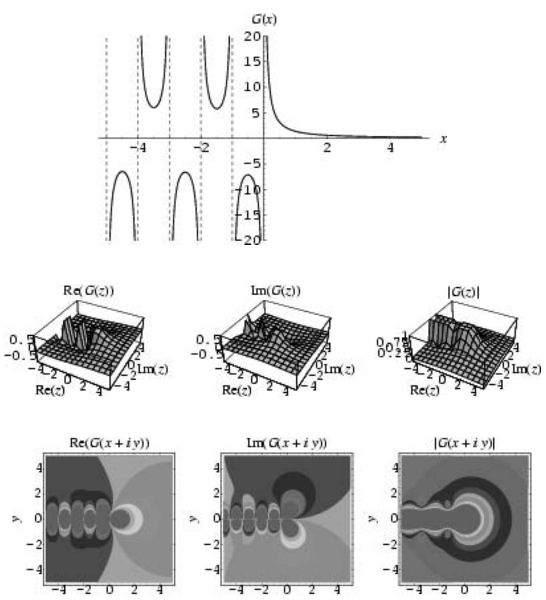
then each EIGENVALUE of the MATRIX of order n is in at least one of the disks

$$\{z : |z - a_{ii}| \leq R_i\}. \tag{2}$$

The theorem can be made stronger as follows. Let r be an INTEGER with $1 \leq r \leq n$, then each EIGENVALUE of is either in one of the disks Γ_1

$$\{z: \ |z-a_{jj}| \leq S_j^{(r-1)}\}, \tag{3}$$

or in one of the regions



$$\left\{z: \sum_{i=1}^{r} |z-a_{ii}| \leq \sum_{i=1}^{r} R_i\right\}, \tag{4}$$

where $S_j^{(r-1)}$ is the sum of magnitudes of the $r-1$ largest off-diagonal elements in column j.

G-Function

As defined by Erdélyi *et al.* (1981, p. 20), the G-function is given by

$$G(z) \equiv \psi_0(\tfrac{1}{2} + hz) - \psi_0(\tfrac{1}{2} z), \tag{1}$$

where $\psi_0(z)$ is the DIGAMMA FUNCTION. Integral representations are given by

$$G(z) = 2\int_0^1 \frac{t^{z-1}}{1+t}\,dt \tag{2}$$

$$= 2\int_0^\infty \frac{e^{-zt}}{1+e^{-t}}\,dt \tag{3}$$

for $\Re[z] > 0$. $G(z)$ is also given by the series

$$G(z) = 2\sum_{n=0}^{\infty} \frac{(-1)^n}{z+n}, \tag{4}$$

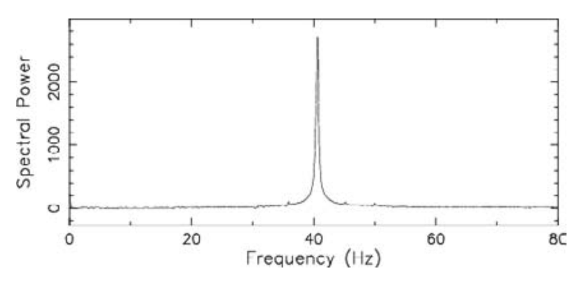
and in terms of the HYPERGEOMETRIC FUNCTION by

$$G(z) = 2z^{-1}\,{}_2F_1(1,\ z;\ 1+z;\ -1). \tag{5}$$

It obeys the functional relations

$$G(1+z) = 2z^{-1} - G(z) \tag{6}$$

$$G(1-z) = 2\pi\csc(\pi z) - G(z) \tag{7}$$



$$G(mz) = \begin{cases} -\dfrac{2}{m}\displaystyle\sum_{r=0}^{m-1}(-1)^r \psi_0(z+\frac{r}{m}) & \text{for } m \text{ even} \\ \dfrac{1}{m}\displaystyle\sum_{r=0}^{m-1}(-1)^r G(z+\frac{r}{m}) & \text{for } m \text{ odd.} \end{cases} \tag{8}$$

Ghost

If the sampling of an interferogram is modulated at a definite frequency instead of being uniformly sampled, spurious spectral features called "ghosts" are produced (Brault 1985). Periodic ruling or sampling errors introduce a modulation superposed on top of the expected fringe pattern due to uniform stage translation. Because modulation is a multiplicative process, spurious features are generated in spectral space at the sum and difference of the true

fringe and ghost fringe frequencies, thus throwing power out of its spectral band.

Ghosts are copies of the actual spectrum, but appear at reduced strength. The above shows the power spectrum for a pure sinusoidal signal sampled by translating a Fourier transform spectrometer mirror at constant speed. The small blips on either side of the main peaks are ghosts.

In order for a ghost to appear, the process producing it must exist for most of the interferogram. However, if the ruling errors are not truly sinusoidal but vary across the length of the screw, a longer travel path can reduce their effect.

Gilbrat's Distribution

A CONTINUOUS DISTRIBUTION in which the LOGARITHM of a variable x has a NORMAL DISTRIBUTION,

$$P(x) = \frac{1}{x\sqrt{2\pi}} e^{-(\ln x)^2/2}, \tag{1}$$

defined over the interval $[0, \infty)$. It is a special case of the LOG NORMAL DISTRIBUTION

$$P(x) = \frac{1}{Sx\sqrt{2\pi}} e^{-(\ln x - M)^2/(2S^2)} \tag{2}$$

with $S = 1$ and $M = 0$, and so has distribution function

$$D(x) = \frac{1}{2}\left[1 + \operatorname{erf}\left(\frac{\ln x}{\sqrt{2}}\right)\right]. \tag{3}$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

then given by

$$\mu = \sqrt{e} \tag{4}$$

$$\sigma^2 = e(e-1) \tag{5}$$

$$\gamma_1 = (e+2)\sqrt{e-1} \tag{6}$$

$$\gamma_2 = e^4 + 2e^3 + 3e^2 - 3. \tag{7}$$

See also Log Normal Distribution

Gilbreath's Conjecture

Let the difference of successive primes be defined by $d_n \equiv p_{n+1} - p_n$, and d_n^k by

$$d_n^k \equiv \begin{cases} d_n & \text{for } k=1 \\ |d_{n+1}^{k-1} - d_n^{k-1}| & \text{for } k > 1. \end{cases}$$

N. L. Gilbreath claimed that $d_1^k = 1$ for all k (Guy 1994). It has been verified for $k < 63{,}419$ and all primes up to $\pi(10^{13})$, where $\pi(x)$ is the prime counting function.

Gill's Method

A formula for numerical solution of differential equations,

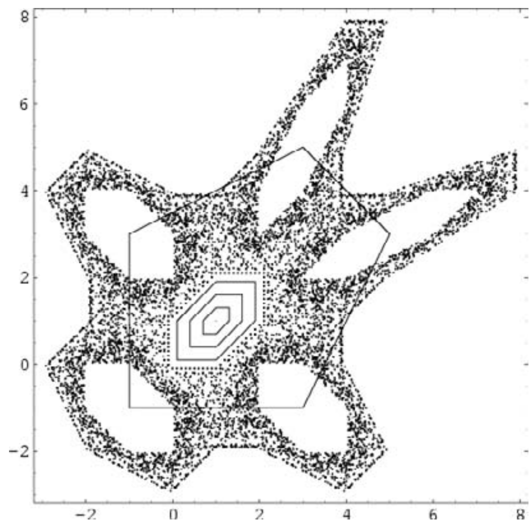
$$y_{n+1} = y_n + \tfrac{1}{6}[k_1 + (2-\sqrt{2})k_2 + (2+\sqrt{2})k_3 + k_4] + \mathcal{O}(h^5),$$

where

$$k_1 = hf(x_n,\ y_n)$$

$$k_2 = hf(x_n + \tfrac{1}{2}h,\ y_n + \tfrac{1}{2}k_1)$$

$$k_3 = hf[x_n + \tfrac{1}{2}h,\ y_n + \tfrac{1}{2}(-1+\sqrt{2})k_1 + (1-\tfrac{1}{2}\sqrt{2})k_2]$$



$$k_4 = hf[x_n + h,\ y_n - \tfrac{1}{2}\sqrt{2}k_2 + (1+\tfrac{1}{2}\sqrt{2})k_3].$$

Gingerbreadman Map

A 2-D piecewise linear map defined by

$$x_{n+1} = 1 - y_n + |x_n|$$

$$y_{n+1} = x_n.$$

The map is chaotic in the filled region above and stable in the six hexagonal regions. Each point in the interior hexagon defined by the vertices (0, 0), (1, 0), (2, 1), (2, 2), (1, 2), and (0, 1) has an orbit with period six (except the point (1, 1), which has period 1). Orbits in the other five hexagonal regions circulate from one to the other. There is a unique orbit of period five, with all others having period 30. The points having orbits of period five are (-1, 3), (-1, -1), (3, -1), (5, 3), and (3, 5), indicated in the above figure by the black line. However, there are infinitely many distinct periodic orbits which have an arbitrarily long period.

Gini Coefficient

This entry contributed by Christian Damgaard

The Gini coefficient (or Gini ratio) G is a summary statistic of the Lorenz curve and a measure of inequality in a population. The Gini coefficient is most easily calculated from unordered size data as the "relative mean difference," i.e., the mean of the difference between every possible pair of individuals, divided by the mean size μ,

$$G = \frac{\sum_{i=1}^{n} \sum_{j=1}^{n} |x_i - x_j|}{2n^2\mu}$$

Alternatively, if the data is ordered by increasing size of individuals, G is given by

$$G = \frac{\sum_{i=1}^{n} (2i - n - 1)x'_i}{n^2\mu}.$$

The Gini coefficient ranges from a minimum value of zero, when all individuals are equal, to a theoretical maximum of one in an infinite population in which every individual except one has a size of zero. It has been shown that the sample Gini coefficients defined above need to be multiplied by $n/(n-1)$ in order to become UNBIASED ESTIMATORS for the *population* coefficients.

Girko's Circular Law

Let λ be (possibly complex) EIGENVALUES of a set of random $n \times n$ REAL MATRICES with entries independent and taken from a standard normal distribution. Then as $n \to \infty$, $\lambda/\sqrt{n}$ is uniformly distributed on the UNIT DISK in the COMPLEX PLANE. For small n, the distribution shows a concentration along the REAL LINE accompanied by a slight paucity above and below (with interesting embedded structure). However, as $n \to \infty$, the concentration about the line disappears and the distribution becomes truly uniform.

Girth

The length of the shortest GRAPH CYCLE (if any) in a GRAPH. Acyclic graphs are considered to have infinite girth (Skiena 1990, p. 191). The girth of a graph may be found using `Girth`[*g*] in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`). The following table gives examples of graphs with various girths.

girth	example

Giuga Number

Any COMPOSITE NUMBER n with $p|(n/p-1)$ for all PRIME DIVISORS p of n. n is a Giuga number IFF

$$\sum_{k=1}^{n-1} k^{\phi(n)} \equiv -1 \pmod n$$

where ϕ is the TOTIENT FUNCTION and IFF

$$\sum_{p|n} \frac{1}{p} - \prod_{p|n} \frac{1}{p} \in \mathbb{N}.$$

n is a Giuga number IFF

$$nB_{\phi(n)} \equiv -1 \pmod n,$$

where B_k is a BERNOULLI NUMBER and ϕ is the TOTIENT FUNCTION. Every counterexample to Giuga's conjecture is a contradiction to ARGOH'S CONJECTURE and vice versa. The smallest known Giuga numbers are 30 (3 factors), 858, 1722 (4 factors), 66198 (5 factors), 2214408306, 24423128562 (6 factors), 432749205173838, 14737133470010574, 550843391309130318 (7 factors), 244197000982499715087866346, 554079914617070801288578559178 (8 factors), ... (Sloane's A007850).

It is not known if there are an infinite number of Giuga numbers. All the above numbers have sum minus product equal to 1, and any Giuga number of higher order must have at least 59 factors. The smallest ODD Giuga number must have at least nine PRIME FACTORS.

Giuga Sequence

A finite, increasing sequence of INTEGERS $\{n_1, \ldots, n_m\}$ such that

$$\sum_{i=1}^{m} \frac{1}{n_i} - \prod_{i=1}^{m} \frac{1}{n_i} \in \mathbb{N}.$$

A sequence is a Giuga sequence IFF it satisfies

$$n_i|(n_1 \cdots n_{i-1} \cdot n_{i+1} \cdot n_m - 1)$$

for $i=1, \ldots, m$. There are no Giuga sequences of length 2, one of length 3 ($\{2, 3, 5\}$), two of length 4 ($\{2, 3, 7, 41\}$ and $\{2, 3, 11, 13\}$), 3 of length 5 ($\{2, 3, 7, 43, 1805\}$, $\{2, 3, 7, 83, 85\}$, and $\{2, 3, 11, 17, 59\}$), 17 of length 6, 27 of length 7, and hundreds of length 8. There are infinitely many Giuga sequences. It is possible to generate longer Giuga sequences from shorter ones satisfying certain properties.

Giuga's Conjecture

If $n>1$ and

$$n|1^{n-1}+2^{n-1}+\ldots+(n-1)^{n-1}+1,$$

is n necessarily a PRIME? In other words, defining

$$s_n \equiv \sum_{k=1}^{n-1} k^{n-1},$$

does there exist a COMPOSITE n such that $s_n \equiv -1 (\mathrm{mod}\, n)$? It is known that $s_n \equiv -1 (\mathrm{mod}\, n)$ IFF for each prime divisor p of n, $(p-1)|(n/p-1)$ and $p|(n/p-1)$ (Giuga 1950, Borwein *et al.* 1996); therefore, any counterexample must be SQUAREFREE. A composite INTEGER n satisfies $s_n \equiv -1 (\mathrm{mod}\, n)$ IFF it is both a CARMICHAEL NUMBER and a GIUGA NUMBER. Giuga showed that there are no exceptions to the conjecture up to 10^{1000}. This was later improved to 10^{1700} (Bedocchi 1985) and 10^{13800} (Borwein *et al.* 1996).

GL

General Linear Group

Glaisher

Glaisher-Kinkelin Constant

Glaisher Constant

Glaisher-Kinkelin Constant

Glaisher-Kinkelin Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Define

$$K(n) \equiv 0^0 1^1 2^2 3^3 \cdots (n-1)^{n-1} \tag{1}$$

$$G(n) \equiv \frac{[\Gamma(n)]^n}{K(n)} = \begin{cases} 1 & \text{if } n = 0 \\ 0!1!2!\cdots(n-1)! & \text{if } n > 0. \end{cases} \tag{2}$$

where $G(n)$ is Barnes' G-function and $K(n)$ is the K-function. Then

$$\lim_{n\to\infty} \frac{K(n+1)}{n^{n^2/2+n/2+1/12}e^{-n^2/4}} = A \tag{3}$$

(Voros 1987) and

$$\lim_{n\to\infty} \frac{G(n)}{n^{n^2/2-1/12}(2\pi)^{n/2}e^{-3n^2/4}} = \frac{e^{1/12}}{A}, \tag{4}$$

where

$$A = \exp[\tfrac{1}{12} - \zeta'(-1)] = 1.28242713\ldots \tag{5}$$

is called the Glaisher-Kinkelin constant (Voros 1987) and $\zeta'(z)$ is the derivative of the Riemann zeta function (Kinkelin 1860, Glaisher 1877, 1878, 1893, 1894). The constant A is implemented in *Mathematica* 4.0 as `Glaisher`.

Glaisher (1877) also obtained

$$A = 2^{7/36}\pi^{-1/6}\exp\left\{\frac{1}{3} + \frac{2}{3}\int_0^{1/2} \ln[\Gamma(x+1)]\,dx\right\}. \tag{6}$$

Glaisher (1894) showed that

$$1^{1/1}2^{1/2}3^{1/9}4^{1/16}5^{1/25}\ldots = \left(\frac{A^{12}}{2\pi e^{\gamma}}\right)^{\pi^2/6} \tag{7}$$

$$1^{1/1}3^{1/9}5^{1/25}7^{1/49}9^{1/81}\ldots = \left(\frac{A^{12}}{2^{4/3}\pi e^{\gamma}}\right)^{\pi^2/8} \tag{8}$$

$$\frac{1^{1/1}5^{1/125}9^{1/729}\ldots}{3^{1/27}7^{1/343}11^{1/1331}\ldots} = \left(\frac{A}{2^{5/32}\pi^{1/32}e^{3/32+\gamma/48+s/4}}\right)^{\pi^3}, \tag{9}$$

where

$$s \equiv \frac{\zeta(3)}{3\cdot4\cdot5}\frac{1}{4^3} + \frac{\zeta(5)}{5\cdot6\cdot7}\frac{1}{4^5} + \frac{\zeta(7)}{7\cdot8\cdot9}\frac{1}{4^7} + \ldots \tag{10}$$

The constant appears in a number of sums and integrals, especially those involving gamma functions and zeta functions (Wolfram 1999, p. 757).

Glide

A product of a reflection in a line and translation along the same line.

See also Reflection, Translation

References

Addington, S. "The Four Types of Symmetry in the Plane." http://forum.swarthmore.edu/sum95/suzanne/symsusan.html.

Glide Reflection

Glide

Glissette

The locus of a point P (or the envelope of a line) fixed in relation to a curve C which slides between fixed curves. For example, if C is a line segment and P a point on the line segment, then P describes an ellipse when C slides so as to touch two orthogonal straight lines. The glissette of the line segment C itself is, in this case, an astroid.

Global Extremum

A GLOBAL MINIMUM or GLOBAL MAXIMUM. It is impossible to construct an algorithm that will find a global extremum for an arbitrary function.

See also LOCAL EXTREMUM

Global Field

A global field is either a NUMBER FIELD, a FUNCTION FIELD on an ALGEBRAIC CURVE, or an extension of TRANSCENDENCE DEGREE one over a FINITE FIELD. From a modern point of view, a global field may refer to a FUNCTION FIELD on a complex ALGEBRAIC CURVE as well as one over a FINITE FIELD. A global field contains a canonical SUBRING, either the ALGEBRAIC INTEGERS or the POLYNOMIALS. By choosing a PRIME IDEAL in its SUBRING, a global field can be TOPOLOGICALLY COMPLETED to give a LOCAL FIELD. For example, the RATIONAL NUMBERS are a global field. By choosing a PRIME NUMBER p, the RATIONALS can be completed in the P-ADIC NORM to form the P-ADIC NUMBERS $\mathbb{Q}_p$.

A global field is called global because of the special case of a complex ALGEBRAIC CURVE, for which the field consists of global functions, (i.e., functions that are defined everywhere). These functions differ from functions defined near a point, whose completion is called a LOCAL FIELD. Under favorable conditions, the local information can be patched together to yield global information (e.g., the HASSE PRINCIPLE).

Globe

A SPHERE which acts as a model of a spherical (or ellipsoidal) celestial body, especially the Earth, and on which the outlines of continents, oceans, etc. are drawn.

See also LATITUDE, LONGITUDE, SPHERE

Glome

A 3-sphere

$$x^2+y^2+z^2+w^2=r^2$$

(as opposed to the usual 2-SPHERE). The term derives from the Latin 'glomus' meaning 'ball of string.'

See also HYPERSPHERE, SPHERE

Glove Problem

Let there be m doctors and $n \le m$ patients, and let all mn possible combinations of examinations of patients

by doctors take place. Then what is the minimum number of surgical gloves needed $G(m, n)$ so that no doctor must wear a glove contaminated by a patient and no patient is exposed to a glove worn by another doctor? In this problem, the gloves can be turned inside out and even placed on top of one another if necessary, but no "decontamination" of gloves is permitted. The optimal solution is

$$g(m, n) = \begin{cases} 2 & m = n = 2 \\ \frac{1}{2}(m+1) & n = 1, \ m = 2k+1 \\ \left\lceil \frac{1}{2}(m) + \frac{2}{3} n \right\rceil & \text{otherwise,} \end{cases}$$

where $\lceil x \rceil$ is the CEILING FUNCTION (Vardi 1991). The case $m = n = 2$ is straightforward since two gloves have a total of four surfaces, which is the number needed for $mn = 4$ examinations.

Glue Vector

A VECTOR specifying how layers are stacked in a LAMINATED LATTICE.

Gnomon

A shape which, when added to a figure, yields another figure SIMILAR to the original.

References

Shanks, D. *Solved and Unsolved Problems in Number Theory, 4th ed.* New York: Chelsea, p. 123, 1993.

Gnomon Magic Square

A 3×3 array of numbers in which the elements in each 2×2 corner have the same sum.

See also MAGIC SQUARE

References

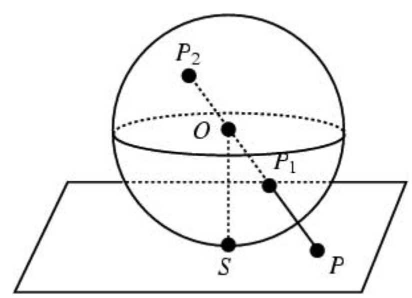
Stapleton, H. E. "The Gnomon as a Possible Link Between (a) One Type of Mesopotamian *Ziggurat* and (b) the Magic Square Numbers on which Jaribian Alchemy was Based." *Ambix: J. Soc. Study Alchemy and Early Chem.* **6**, 1–, 1957–958.

Gnomonic Number

A FIGURATE NUMBER OF THE FORM $g_n = 2n - 1$ which are the areas of square gnomons, obtained by removing a SQUARE of side $n-1$ from a SQUARE of side n,

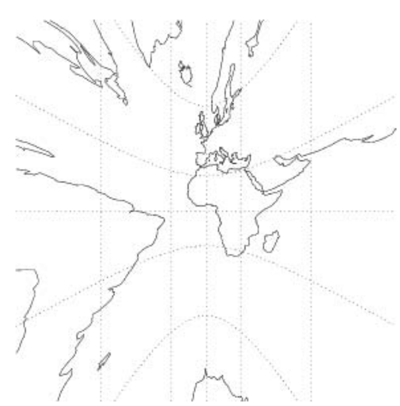
$$g_n = n^2 - (n-1)^2 = 2n - 1.$$

The gnomonic numbers are therefore equivalent to the ODD NUMBERS, and the first few are 1, 3, 5, 7, 9, 11, ... (Sloane's A005408). The GENERATING FUNCTION for the gnomonic numbers is



$$\frac{x(1+x)}{(x-1)^2} = x + 3x^2 + 5x^3 + 7x^4 + \ldots.$$

See also FIGURATE NUMBER, ODD NUMBER



References

Sloane, N. J. A. Sequences A005408/M2400 in "An On-Line Version of the Encyclopedia of Integer Sequences." http://www.research.att.com/~njas/sequences/eisonline.html.

Gnomonic Projection

A nonconformal MAP PROJECTION obtained by projecting points P_1 (or P_2) on the surface of sphere from a sphere's center O to point P in a plane that is tangent to the south pole S (Coxeter 1969, p. 93). Since this projection obviously sends ANTIPODAL POINTS P_1 and P_2 to the same point P in the plane, it can only be used to project one HEMISPHERE as a time. In a gnomonic projection, ORTHODROMES are straight LINES.

The transformation equations for a point at LATITUDE

ϕ and LONGITUDE λ are given by

$$x = \frac{\cos\phi \sin(\lambda - \lambda_0)}{\cos c} \quad (1)$$

$$y = \frac{\cos\phi_1 \sin\phi - \sin\phi_1 \cos\phi \cos(\lambda - \lambda_0)}{\cos c}, \quad (2)$$

where λ_0 is the central longitude, ϕ_1 is the central latitude, and c is the angular distance of the point (x, y) from the center of the projection, given by

$$\cos c = \sin\phi_1 \sin\phi + \cos\phi_1 \cos\phi \cos(\lambda - \lambda_0). \quad (3)$$

The inverse FORMULAS are

$$\phi = \sin^{-1}\left(\cos\phi \sin\phi_1 + \frac{y \sin\theta \cos\theta \cos\phi_1}{\sqrt{x^2 + y^2}}\right), \quad (4)$$

$$\lambda = \lambda_0 + \tan^{-1}\left(\frac{x \sin\theta}{\sqrt{x^2 + y^2}\cos\phi_1 \cos\theta - y \sin\phi_1 \sin\theta}\right), \quad (5)$$

where

$$\theta = \tan^{-1}(\sqrt{x^2 + y^2}). \quad (6)$$

Goat Grazing Problem

GOAT PROBLEM

Goat Problem

Let a circular field of unit radius be fenced in, and tie a goat to a point on the interior of the fence with a chain of length r. What length of chain must be used in order to allow the goat to graze exactly one half the area of the field?

The answer is obtained by using the equation for a CIRCLE-CIRCLE INTERSECTION

$$A = r^2 \cos^{-1}\left(\frac{d^2 + r^2 + R^2}{2dr}\right) + R^2 \cos^{-1}\left(\frac{d^2 + R^2 + -r^2}{2dR}\right) - \tfrac{1}{2}\sqrt{(-d+r+R)(d+r-R)(d-r+R)(d+r+R)} \quad (1)$$

with $R = d = 1$ and $A = \pi/2$ (i.e., half of πR^2). This leads to the equation

$$-\tfrac{1}{2} r\sqrt{4 - r^2} + r^2 \cos^{-1}(\tfrac{1}{2} r) + \cos^{-1}(1 - \tfrac{1}{2} r^2) = \tfrac{1}{2}\pi, \quad (2)$$

which cannot be solved exactly, but which has approximate solution

$$r \approx 1.15872847. \quad (3)$$

See also CIRCLE-CIRCLE INTERSECTION, LENS

Göbel's Sequence

Consider the RECURRENCE RELATION

$$x_n = \frac{1 + x_0^2 + x_1^2 + \ldots + x_{n-1}^2}{n}, \quad (1)$$

with $x_0 = 1$. The first few iterates of x_n are 1, 2, 3, 5,

10, 28, 154, ... (Sloane's A003504). The terms grow extremely rapidly, but are given by the asymptotic formula

$$x_n \approx (n^2 + 2n - 1 + 4n^{-1} - 21n^{-2} + 137n^{-3} - \ldots)C^{2^n}, \quad (2)$$

where

$$C = 1.04783144757641122955990946274313755459\ldots \quad (3)$$

(Zagier). It is more convenient to work with the transformed sequence

$$s_n = 2 + x_1^2 + x_2^2 + \ldots + x_{n-1}^2 = nx_n, \quad (4)$$

which gives the new recurrence

$$s_{n+1} = s_n + \frac{s_n^2}{n^2} \quad (5)$$

with initial condition $s_1 = 2$. Now, s_{n+1} will be nonintegral IFF $n \nmid s_n$. The smallest p for which $s_p \not\equiv 0 \pmod{p}$ therefore gives the smallest nonintegral s_{p+1}. In addition, since $p \nmid s_p$, $x_p = s_p/p$ is also the smallest nonintegral x_p.

For example, we have the sequences $\{s_n \pmod{k}\}_{n=1}^k$:

$$2,\ 6 \equiv 2,\ \tfrac{5}{4} \equiv 0,\ 0,\ 0 \pmod{5} \quad (6)$$

$$2,\ 6,\ 15 \equiv 1,\ \tfrac{5}{4} \equiv 0,\ 0,\ 0,\ 0 \pmod{7} \quad (7)$$

$$2,\ 6,\ 15 \equiv 4,\ \tfrac{52}{9} \equiv 7,\ \tfrac{161}{16} \equiv 8,\ \tfrac{264}{5} \equiv 0,\ 0,\ \ldots,\ 0 \pmod{11} \quad (8)$$

Testing values of k shows that the first nonintegral x_n is x_{43}. Note that a direct verification of this fact is impossible since

$$x_{43} \approx 5.4093 \times 10^{178485291567} \quad (9)$$

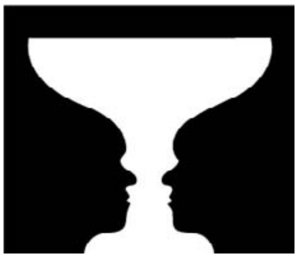
(calculated using the asymptotic formula) is much too large to be computed and stored explicitly.

A sequence even more striking for assuming integer values only for many terms is the 3-Göbel sequence

$$x_n = \frac{1 + x_0^3 + x_1^3 + \ldots + x_{n-1}^3}{n}. \quad (10)$$

The first few terms of this sequence are 1, 2, 5, 45, 22815, ... (Sloane's A005166).

The Göbel sequences can be generalized to k powers by



$$x_n = \frac{1 + x_0^k + x_1^k + \ldots + x_{n-1}^k}{n}. \quad (11)$$

Gödel Number

A Gödel number is a unique number associated with a statement about arithmetic. It is formed as the PRODUCT of successive PRIMES raised to the POWER of the number corresponding to the individual symbols that comprise the sentence. For example, the statement $(\exists x)(x = sy)$ that reads "there EXISTS an x such that x is the immediate SUCCESSOR of y" is coded

$$(2^8)(3^4)(5^{13})(7^9)(11^8)(13^{13})(17^5)(19^7)(23^{16})(29^9),$$

where the numbers in the set (8, 4, 13, 9, 8, 13, 5, 7, 16, 9) correspond to the symbols that make up $(\exists x)(x = sy)$.

Gödel's Incompleteness Theorem

Informally, Gödel's incompleteness theorem states that all CONSISTENT axiomatic formulations of NUMBER THEORY include undecidable propositions (Hofstadter 1989). This is sometimes called Gödel's first incompleteness theorem, and answers in the negative HILBERT'S PROBLEM asking whether mathematics is "complete" (in the sense that every statement in the language of NUMBER THEORY can be either proved or disproved). Formally, Gödel's theorem states, "To every ω-consistent recursive class κ of FORMULAS, there correspond recursive class-signs r such that neither (v Gen r) nor Neg(v Gen r) belongs to Flg(κ), where v is the FREE VARIABLE of r" (Gödel 1931).

A statement sometimes known as Gödel's second incompleteness theorem states that if NUMBER THEORY is consistent, then a proof of this fact does not exist using the methods of first-order PREDICATE CALCULUS. Stated more colloquially, any formal system that is interesting enough to formulate its own consistency can prove its own consistency IFF it is inconsistent.

Gerhard Gentzen showed that the consistency and completeness of arithmetic can be proved if "transfinite" induction is used. However, this approach does not allow proof of the consistency of all mathematics.

RUDIN-SHAPIRO SEQUENCE

Goldbach Conjecture

Goldbach's original conjecture (sometimes called the "ternary" Goldbach conjecture), written in a June 7, 1742 letter to Euler, states that every INTEGER > 5 is the SUM of three PRIMES (Dickson 1957, p. 421). As re-expressed by Euler, an equivalent of this CONJECTURE (called the "strong" or "binary" Goldbach conjecture) asserts that all POSITIVE EVEN INTEGERS ≥ 4 can be expressed as the SUM of two PRIMES. According to Hardy (1999, p. 19), "It is comparatively easy to make clever guesses; indeed there are theorems, like 'Goldbach's Theorem', which have never been proved and which any fool could have guessed."

Schnirelman (1939) proved that every EVEN number can be written as the sum of not more than 300,000 PRIMES (Dunham 1990), which seems a rather far cry from a proof for *two* PRIMES! Pogorzelski (1977) claimed to have proven the Goldbach conjecture, but his proof is not generally accepted (Shanks 1993). The following table summarizes bounds n such that the strong Goldbach conjecture has been shown to be true for numbers $< n$.

bound	reference
1×10^4	Desboves 1885
1×10^5	Pipping 1938
1×10^8	Stein and Stein 1965ab
2×10^{10}	Granville *et al.* 1989
4×10^{11}	Sinisalo 1993
1×10^{14}	Deshouillers *et al.* 1998
4×10^{14}	Richstein 2000 (quoted in Peterson 2000)

The conjecture that all ODD numbers ≥ 9 are the SUM of three ODD PRIMES is called the "weak" Goldbach conjecture. Vinogradov proved that all ODD INTEGERS starting at some sufficiently large value are the SUM of three PRIMES (Guy 1994). The original "sufficiently large" $N \geq 3^{3^{15}} \approx e^{e^{16.573}} \approx 3.25 \times 10^{6,846,168}$ was subsequently reduced to $e^{e^{11.503}} \approx 3.33 \times 10^{43,\ 000}$ by Chen and Wang (1989). Chen (1973, 1978) also showed that all sufficiently large EVEN NUMBERS are the sum of a PRIME and the PRODUCT of at most two PRIMES (Guy 1994, Courant and Robbins 1996).

It has been shown that if the weak Goldbach conjecture is false, then there are only a FINITE number of exceptions. A stronger version of the weak conjecture, namely that every odd number > 5 can be expressed as the sum of a prime plus twice a prime has been formulated by C. Eaton. This conjecture has been verified for $n \leq 10^9$ (Corbit).

Other variants of the Goldbach conjecture include the statements that every EVEN number ≥ 6 is the SUM of two ODD PRIMES, and every INTEGER > 17 the sum of exactly three distinct PRIMES. Let $R(n)$ be the number of representations of an EVEN INTEGER n as the sum of two PRIMES. Then the "extended" Goldbach conjecture states that

$$R(n) \sim 2 \prod_2 \prod_{\substack{k=2 \\ p_k | n}} \frac{p_k - 1}{p_k - 2} \int_2^x \frac{dx}{(\ln x)^2},$$

where $\prod_2$ is the TWIN PRIMES CONSTANT (Halberstam and Richert 1974).

If the Goldbach conjecture is true, then for every number m, there are PRIMES p and q such that

$$\phi(p) + \phi(q) = 2m,$$

where $\phi(x)$ is the TOTIENT FUNCTION (Guy 1994, p. 105).

Vinogradov (1937ab, 1954) proved that every sufficiently large ODD NUMBER is the sum of three PRIMES (Nagell 1951, p. 66), and Estermann (1938) proves that almost all EVEN NUMBERS are the sums of two PRIMES.

Goldbach Number

A positive integer which is the sum of two ODD PRIMES is called a Goldbach number (Li 1999). Let $E(x)$ (the "exceptional set of Goldbach numbers") denote the number of even numbers not exceeding x which

cannot be written as a sum of two primes. Then the GOLDBACH CONJECTURE is equivalent to proving that $E(x) = 2$ for every $x \geq 4$. Li (1999) proved that for sufficiently large x,

$$E(x) = \mathcal{O}(x^{0.921}).$$

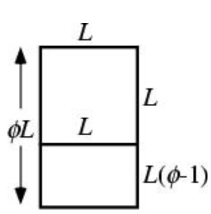
Goldbach's Theorem

GOLDBACH CONJECTURE



Golden Mean

GOLDEN RATIO

Golden Ratio

A number often encountered when taking the ratios of distances in simple geometric figures such as the PENTAGRAM, DECAGON and DODECAGON. It is denoted ϕ, or sometimes τ (which is an abbreviation of the Greek "tome," meaning "to cut"). ϕ is also known as the DIVINE PROPORTION, GOLDEN MEAN, and GOLDEN SECTION and is a PISOT-VIJAYARAGHAVAN CONSTANT. It has surprising connections with CONTINUED FRACTIONS and the EUCLIDEAN ALGORITHM for computing the GREATEST COMMON DIVISOR of two INTEGERS.

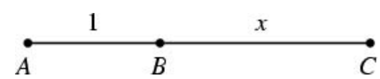
Given a RECTANGLE having sides in the ratio $1 : \phi$, ϕ is defined such that partitioning the original RECTANGLE into a SQUARE and new RECTANGLE results in a new RECTANGLE having sides with a ratio $1 : \phi$. Such a RECTANGLE is called a GOLDEN RECTANGLE, and successive points dividing a GOLDEN RECTANGLE into SQUARES lie on a LOGARITHMIC SPIRAL. This figure is known as a WHIRLING SQUARE.

This means that

$$\frac{1}{\phi - 1} = \phi \tag{1}$$

$$\phi^2 - \phi - 1 = 0. \tag{2}$$

So, by the QUADRATIC EQUATION,



$$\phi = \tfrac{1}{2}(1 \pm \sqrt{1+4}) = \tfrac{1}{2}(1+\sqrt{5}) \tag{3}$$

$$= 1.618033988749894848204586834365638117720\ldots \tag{4}$$

(Sloane's A001622). The golden ratio is given by the INFINITE SERIES

$$\phi = \frac{13}{8} + \sum_{n=0}^{\infty} \frac{(-1)^{n+1}(2n+1)!}{(n+2)!n!4^{2n+3}} \tag{5}$$

(B. Roselle).

A geometric definition can be given in terms of the above figure. Let the ratio $x \equiv BC/AB$. The NUMERATOR and DENOMINATOR can then be taken as $\overline{AB} = a$ and $\overline{BC} = x$ without loss of generality. Now define the position of B by

$$\frac{AB}{BC} = \frac{BC}{AC}. \tag{6}$$

Plugging in gives

$$\frac{1}{x} = \frac{x}{1+x}, \tag{7}$$

or

$$x^2 - x - 1 = 0, \tag{8}$$

which can be solved using the QUADRATIC EQUATION to obtain

$$\phi \equiv x = \frac{1 + \sqrt{(-1)^2 - 4(1)(-1)}}{2} = \tfrac{1}{2}(1+\sqrt{5}), \tag{9}$$

where the plus sign has been taken to give the solution with $x > 1$.

ϕ is the "most" IRRATIONAL number because it has a CONTINUED FRACTION representation

$$\phi = [1,\ 1,\ 1,\ \ldots] \tag{10}$$

(Sloane's A000012; Williams 1979, p. 52; Steinhaus 1983, p. 45). Another infinite representation in terms of a NESTED RADICAL is

$$\phi = \sqrt{1+\sqrt{1+\sqrt{1+\sqrt{1+\ldots}}}}. \tag{11}$$

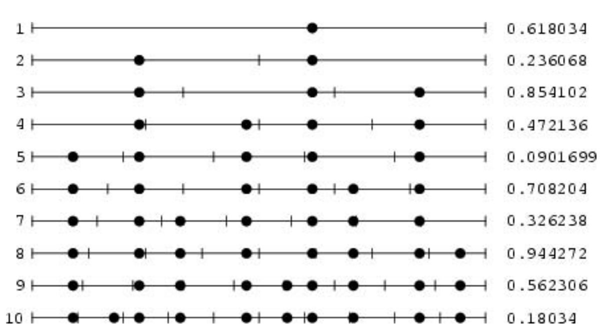
Ramanujan gave the curious CONTINUED FRACTION identities

$$\frac{1}{(\sqrt{\phi\sqrt{5}})e^{2\pi/5}} = 1 + \cfrac{e^{-2\pi}}{1 + \cfrac{e^{-4\pi}}{1 + \cfrac{e^{-6\pi}}{1 + \cfrac{e^{-8\pi}}{1 + \cfrac{e^{-10\pi}}{1 + \ldots}}}}} \tag{12}$$

$$\frac{1}{\left\{\frac{\sqrt{5}}{1 + [5^{3/4}(\phi - 1)^{5/2} - 1] - \phi}\right\} e^{2\pi/\sqrt{5}}} = 1 + \cfrac{e^{-2\pi\sqrt{5}}}{1 + \cfrac{e^{-4\pi\sqrt{5}}}{1 + \cfrac{e^{-6\pi\sqrt{5}}}{1 + \cfrac{e^{-8\pi\sqrt{5}}}{1 + \cfrac{e^{-10\pi\sqrt{5}}}{1 + \ldots}}}}} \tag{13}$$

(Ramanathan 1984).

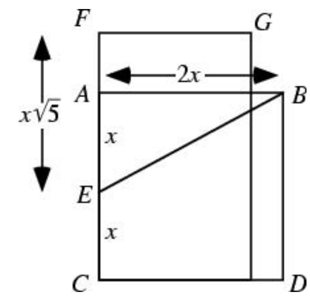
The SINE of certain complex numbers involving ϕ gives particularly simplex answers,



$$\sin(i \ln \phi) = \tfrac{1}{2} i \tag{14}$$

$$\sin(\tfrac{1}{2}\pi - i \ln \phi) = \tfrac{1}{2}\sqrt{5} \tag{15}$$

(Hoey). A curious approximation due to D. Barron is given by



$$\phi \approx \tfrac{1}{2} K^{\gamma - 19/7} \pi^{2/7 + \gamma}, \tag{16}$$

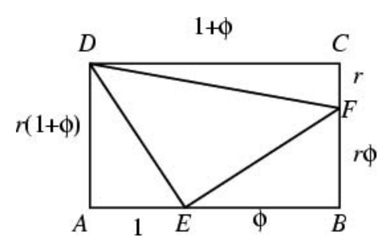
where K is CATALAN'S CONSTANT and γ is the EULER-MASCHERONI CONSTANT, which is good to two digits.

Steinhaus (1983, pp. 48–9) considers the distribution of the FRACTIONAL PARTS of $n\phi$ in the intervals bounded by 0, $1/n$, $2/n$, ..., $(n-1)/n$, 1, and notes that they are much more uniformly distributed than would be expected due to chance (i.e., frac$(n\phi)$ is close to an EQUIDISTRIBUTED SEQUENCE). In particular, the number of empty intervals for $n = 1, 2, \ldots$, are a mere 0, 0, 0, 0, 0, 0, 1, 0, 2, 0, 1, 1, 0, 2, 2, ... (Sloane's A036412). The values of n for which *no* bins are left blank are then given by 1, 2, 3, 4, 5, 6, 8, 10, 13, 16, 21, 34, 55, 89, 144, ... (Sloane's A036413). Steinhaus (1983) remarks that the highly uniform distribution has its roots in the CONTINUED FRACTION for ϕ.

The legs of a GOLDEN TRIANGLE are in a golden ratio to its base. In fact, this was the method used by Pythagoras to construct ϕ. Euclid used the following construction.

Draw the SQUARE $\square ABCD$, call E the MIDPOINT of AC, so that $AE = EC \equiv x$. Now draw the segment BE, which has length

$$x\sqrt{2^2 + 1^2} = x\sqrt{5}, \tag{17}$$



and construct EF with this length. Now construct $FG = EF$, then

$$\phi = \frac{FC}{CD} = \frac{EF + CE}{CD} = \frac{x(\sqrt{5} + 1)}{2x} = \tfrac{1}{2}(\sqrt{5} + 1). \tag{18}$$

The ratio of the CIRCUMRADIUS to the length of the side of a DECAGON is also ϕ,

$$\frac{R}{s} = \tfrac{1}{2}\csc\left(\frac{\pi}{10}\right) = \tfrac{1}{2}(1 + \sqrt{5}) = \phi. \tag{19}$$

Similarly, the legs of a GOLDEN TRIANGLE (an ISOSCELES TRIANGLE with a VERTEX ANGLE of 36°) are in a golden ratio to the base. Bisecting a GAULLIST CROSS also gives a golden ratio (Gardner 1961, p. 102).

In the figure above, three TRIANGLES can be INSCRIBED in the RECTANGLE $\square ABCD$ of arbitrary aspect ratio 1 : r such that the three RIGHT TRIANGLES have equal areas by dividing AB and BC in the golden ratio. Then

$$K_{\Delta ADE} = \tfrac{1}{2} \cdot r(1 + \phi) \cdot 1 = \tfrac{1}{2} r\phi^2 \tag{20}$$

$$K_{\Delta BEF} = \tfrac{1}{2} \cdot r\phi \cdot \phi = \tfrac{1}{2} r\phi^2 \tag{21}$$

$$K_{\Delta CDF} = \tfrac{1}{2}(1 + \phi) \cdot r = \tfrac{1}{2} r\phi^2, \tag{22}$$

which are all equal.

The golden ratio also satisfies the RECURRENCE RELATION

$$\phi^n = \phi^{n-1} + \phi^{n-2}, \tag{23}$$

so taking $n = 0$ gives

$$\phi = \phi^{-1} + 1. \tag{24}$$

The powers of the golden ratio also satisfy

$$\phi^n = F_n \phi + F_{n-1}, \tag{25}$$

where F_n is a FIBONACCI NUMBER (Wells 1986, p. 39). For the difference equations

$$\begin{cases} x_0 = 1 \\ x_n = 1 + \dfrac{1}{x_{n-1}} \quad \text{for } n = 1,\ 2,\ 3, \end{cases} \tag{26}$$

ϕ is also given by

$$\phi = \lim_{n\to\infty} x_n. \tag{27}$$

In addition,

$$\phi = \lim_{n\to\infty} \frac{F_n}{F_{n-1}}, \tag{28}$$

where F_n is the nth FIBONACCI NUMBER, as first proved by Scottish mathematician Robert Simson in 1753 (Wells 1986, p. 62).

The SUBSTITUTION MAP

$$0 \to 01 \tag{29}$$

$$1 \to 0 \tag{30}$$

gives

$$0 \to 01 \to 010 \to 01001 \to \ldots, \tag{31}$$

giving rise to the sequence

$$0100101001001010010100100101\ldots \tag{32}$$

(Sloane's A003849). Here, the zeros occur at positions 1, 3, 4, 6, 8, 9, 11, 12, ... (Sloane's A000201), and the ones occur at positions 2, 5, 7, 10, 13, 15, 18, ... (Sloane's A001950). These are complementary BEATTY SEQUENCES generated by $\lfloor n\phi \rfloor$ and $\lfloor n\phi^2 \rfloor$. The sequence also has many connections with the FIBONACCI NUMBERS.

Salem showed that the set of PISOT-VIJAYARAGHAVAN CONSTANTS is closed, with ϕ the smallest accumulation point of the set (Le Lionnais 1983).

Golden Ratio Conjugate

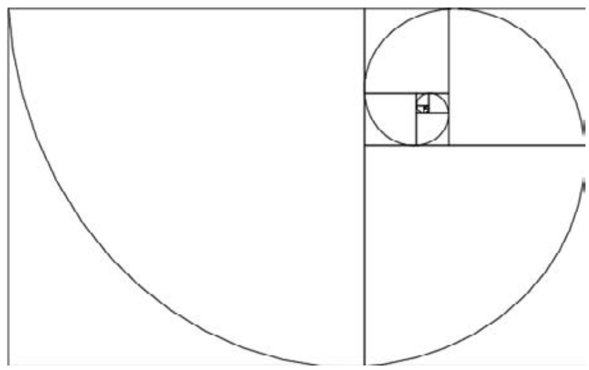
The quantity

$$\phi_C \equiv \frac{1}{\phi} = \phi - 1 = \frac{\sqrt{5}-1}{2} \approx 0.6180339887, \tag{1}$$

where ϕ is the GOLDEN RATIO. The golden ratio conjugate is sometimes also called the SILVER RATIO. A quantity similar to the FEIGENBAUM CONSTANT can be found for the nth CONTINUED FRACTION representation

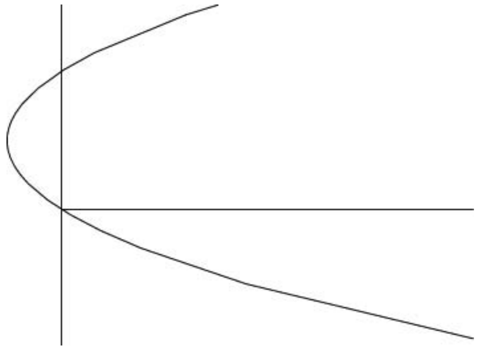
$$[a_0,\ a_1,\ a_2,\ \ldots]. \tag{2}$$

Taking the limit of



$$\delta_n \equiv \frac{\sigma_n - \sigma_{n-1}}{\sigma_n - \sigma_{n+1}} \tag{3}$$

gives



$$\delta \equiv \lim_{n\to\infty} = 1 + \phi = 2 + \phi_C. \tag{4}$$

See also GOLDEN RATIO, SILVER RATIO

Golden Rectangle

Given a RECTANGLE having sides in the ratio $1 : \phi$, the GOLDEN RATIO ϕ is defined such that partitioning the original RECTANGLE into a SQUARE and new RECTANGLE results in a new RECTANGLE having sides with a ratio $1 : \phi$. Such a RECTANGLE is called a golden rectangle, and successive points dividing a golden rectangle into SQUARES lie on a LOGARITHMIC SPIRAL (Wells 1986, p. 39). The spiral is not actually tangent at these points, however, but passes through them and intersects the adjacent side, as illustrated below.

If the top left corner of the original square is positioned at (0, 0), the center of the spiral occurs at the position

$$x_0 = \sum_{n=0}^{\infty}\left(\frac{1}{\phi^{4n}} + \frac{1}{\phi^{4n+1}} - \frac{1}{\phi^{4n+2}} - \frac{1}{\phi^{4n+3}}\right)$$
$$= (1 + \phi^{-1} - \phi^{-2} - \phi^{-3})\sum_{n=0}^{\infty}\frac{1}{\phi^{4n}} = \frac{2\phi+1}{\phi+2}$$
$$= \tfrac{1}{10}(5 + 3\sqrt{5}) \approx 1.17082 \tag{1}$$

$$y_0 = \sum_{n=0}^{\infty}\left(-\frac{1}{\phi^{4n}} + \frac{1}{\phi^{4n+1}} + \frac{1}{\phi^{4n+2}} - \frac{1}{\phi^{4n+3}}\right)$$
$$= (-1 + \phi^{-1} + \phi^{-2} - \phi^{-3})\sum_{n=0}^{\infty} - \frac{1}{2+\phi}$$
$$= \tfrac{1}{10}(\sqrt{5} - 5) \approx -0.276393, \tag{2}$$

and the parameters of the spiral $ae^{b\theta}$ are given by

$$a = (\tfrac{4}{5})^{1/4}\phi^{(\tan^{-1} 2)/\pi} \tag{3}$$

$$b = \frac{2\ln\phi}{\pi} \approx 0.306349. \tag{4}$$

Golden Section

GOLDEN RATIO

Golden Theorem

QUADRATIC RECIPROCITY THEOREM

Golden Triangle

An ISOSCELES TRIANGLE with VERTEX angles 36°. Such TRIANGLES occur in the PENTAGRAM and DECAGON. The legs are in a GOLDEN RATIO to the base. For such a TRIANGLE,

$$\sin(18^\circ) = \sin(\tfrac{1}{10}\pi) = \frac{\frac{1}{2}b}{l} \quad (1)$$

$$b = 2a\sin(\tfrac{1}{10}\pi) = 2a\frac{\sqrt{5}-1}{4} = \tfrac{1}{2}a(\sqrt{5}-1) \quad (2)$$

$$b + l = \tfrac{1}{2}a(\sqrt{5}+1) \quad (3)$$

$$\frac{b+a}{a} = \frac{\sqrt{5}+1}{2} = \phi. \quad (4)$$

Kimberling (1991) defines a second type of golden triangle in which the ratio of angles is $\phi : 1$, where ϕ is the GOLDEN RATIO.

Goldschmidt Solution

The discontinuous solution of the SURFACE OF REVOLUTION AREA minimization problem for surfaces connecting two CIRCLES. When the CIRCLES are sufficiently far apart, the usual CATENOID is no longer stable and the surface will break and form two surfaces with the CIRCLES as boundaries.

See also CALCULUS OF VARIATIONS, SURFACE OF REVOLUTION

Göllnitz's Theorem

Let $A(n)$ denote the number of PARTITIONS of n into parts $\equiv 2,\ 5,\ 11 \pmod{12}$, let $B(n)$ denote the number of PARTITIONS of n into distinct parts $\equiv 2,\ 4,\ 5 \pmod{6}$, and let $C(n)$ denote the number of PARTITIONS of n of the form

$$n = b_1 + b_2 + \ldots + b_t, \quad (1)$$

where $b_i - b_{i+1} \geq 6$, with strict inequality if $b_i \equiv 0,\ 1$ or $3 \pmod 6$, and $b_t \neq 1,\ 3$. Then

$$A(n) = B(n) = C(n) \quad (2)$$

(Andrews 1986, p. 101).

The values of $A(n) = B(n) = C(n)$ for $n = 1, 2, \ldots$ are 0, 1, 0, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 3, 3, 4, 4, 4, 5, 5, 6, 7, 7, 8, 9, ... (Sloane's A056970). For example, for $n = 24$, there are eight partitions satisfying these conditions, as summarized in the following table.

$A(24) = 8$	$B(24) = 8$	$C(24) = 8$
$17+5+2$	$22+2$	24
$14+5+5$	$20+4$	$22+2$
$14+2+2+2+2+2$	$17+5+2$	$20+4$
$11+11+2$	$16+8$	$19+5$
$11+5+2+2+2+2$	$14+10$	$18+6$
$5+5+5+5+2+2$	$14+8+2$	$17+$
$5+5+2+2+2+2+2+2+2$	$11+8+5$	$16+8$
$2+2+2+2+2+2+2+2+2+2+2+2$	$10+8+4+2$	$14+8+2$

The identity $A(n) = B(n)$ can be established using the identity

$$\sum_{n=0}^{\infty} B(n)q^n = \prod_{n=0}^{\infty} (1+q^{6n+2})(1+q^{6n+4})(1+q^{6n+5}) \quad (3)$$

$$= \prod_{n=0}^{\infty} \frac{(1-q^{12n+4})(1-q^{12n+8})(1-q^{12n+10})}{(1-q^{6n+2})(1-q^{6n+4})(1-q^{6n+5})} \quad (4)$$

$$= \prod_{n=0}^{\infty} \frac{1}{(1 - q^{12n+2})(1 - q^{12n+5})(1 - q^{12n+11})} \quad (5)$$

$$= \sum_{n=0}^{\infty} A(n) q^n \quad (6)$$

(Andrews 1986, p. 101). The assertion $B(n) = C(n)$ is significantly more difficult, and no simple proof is known. However, it can be established with the aid of computer algebra and the following refinement of the Göllnitz theorem.

Let $B(n, m)$ denote the number of partitions of n into m distinct parts $\equiv 2, 4, 5, 4, 5 \pmod 6$. Let $C(n, m)$ denote the number of partitions of n of the form

$$n = b_1 + b_2 + \ldots + b_n, \quad (7)$$

where $b_i - b_{i+1} \geq 6$, with strict inequality if $b_i = 0, 1, 3 \pmod 6$, where $b_s \neq 1, 3$, and m is the number of $b_i \equiv 2, 4, 5$ plus twice the number of $b_i \equiv 0, 1, 3$. Then $B(n, m) = C(n, m)$ for each n and m (Göllnitz 1967; Andrews 1986, p. 102).

Golomb Constant

GOLOMB-DICKMAN CONSTANT

Golomb Ruler

An n-mark Golomb ruler is a set of n distinct nonnegative integers $(a_1, a_2, \ldots, a_n)$, called "marks," such that the positive differences $|a_i - a_j|$, computed over all possible pairs of different integers, are distinct. Let a_n be the largest integer in an n-mark Golomb ruler. Then an *optimal* Golomb ruler with n marks is an n-mark Golomb ruler having largest mark a_n characterized by the property that there exist no other n-mark Golomb rulers having smaller a_n. In such a case, a_n is the called the "length" of the optimal n-mark ruler.

For example, the set (0, 1, 3, 7) is 4-mark Golomb ruler since its differences are $(1 = 1-, 2 = 3-, 3 = 3-, 4 = 7-, 6 = 7-, 7 = 7-)$, all of which are distinct. However, the unique optimal Golomb 4-mark ruler is (0, 1, 4, 6), which measures the distances (1, 2, 3, 4, 5, 6) (and is therefore also a PERFECT RULER). As a further example, it turns out that the length of an optimal 6-mark Golomb ruler is 17. In fact, there are a total of four distinct 6-mark Golomb rulers, all of length 17, one of which is given by (0, 1, 4, 10, 12, 17).

In general, the lengths of the optimal n-mark Golomb rulers for $n = 2, 3, 4, \ldots$ are 1, 3, 6, 11, 17, 25, 34, ... (Sloane's A003022, Vanderschel and Garry). Although the lengths of the optimal n-mark Golomb rulers are not known for $n \geq 23$, the known 21, 22, and 23-mark rulers were proved optimal by the Golomb ruler search project in 1998 and 1999. The number of inequivalent optimal n-mark Golomb rulers for $n = 2, 3, \ldots$ are 1, 1, 1, 2, 4, 5, 1, 1, 1, ... (Sloane's A036501), and the number of distances in an optimal n-mark ruler is given by the TRIANGULAR NUMBER $T_n = n(n-1)/2$, so for $n = 1, 2, \ldots$, the first few are 0, 1, 3, 6, 10, 15, ... (Sloane's A000217).

The following table gives the optimal Golomb rulers for small n. A more complete table is maintained by J. B. Shearer.

n	optimal rulers
2	(0, 1)
3	(0, 1, 3)
4	(0, 1, 4, 6)

5	(0, 1, 4, 9, 11), (0, 3, 4, 9, 11)
6	(0, 1, 4, 10, 12, 17), (0, 1, 4, 10, 15, 17), (0, 3, 5, 9, 16, 17),
	(0, 4, 6, 9, 16, 17)
7	(0, 1, 4, 10, 18, 23, 25), (0, 2, 3, 10, 16, 21, 25),
	(0, 2, 6, 9, 14, 24, 25), (0, 1, 7, 11, 20, 23, 25), (0, 3, 4, 12, 18, 23, 25)
8	(0, 1, 4, 9, 15, 22, 32, 34)

Golomb-Dickman Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let Π be a PERMUTATION of n elements, and let α_i be the number of CYCLES of length i in this PERMUTATION. Picking Π at RANDOM gives

$$\left\langle \sum_{j=1}^{\infty} \alpha_j \right\rangle = \sum_{i=1}^{n} \frac{1}{i} = \ln n + \gamma + \mathcal{O}\left(\frac{1}{n}\right) \tag{1}$$

$$\operatorname{var}\left(\sum_{j=1}^{\infty} \alpha_j\right) = \sum_{i=1}^{n} \frac{i-1}{i^2} = \ln n + \gamma - \tfrac{1}{6}\pi^2 + \mathcal{O}\left(\frac{1}{n}\right) \tag{2}$$

$$\lim_{n\to\infty} P(\alpha_1 = 0) = \frac{1}{e} \tag{3}$$

(Shepp and Lloyd 1966, Wilf 1990). Goncharov (1942) showed that

$$\lim_{n\to\infty} P(\alpha_j = k) = \frac{1}{k!}\, e^{-1/j} j^{-k}, \tag{4}$$

which is a POISSON DISTRIBUTION, and

$$\lim_{n\to\infty} P\left[\left(\sum_{j=1}^{\infty} \alpha_j - \ln n\right)(\ln n)^{-1/2} \le x\right] = \Phi(x), \tag{5}$$

which is a NORMAL DISTRIBUTION, γ is the EULER-MASCHERONI CONSTANT, and $\Phi(x)$ is the NORMAL DISTRIBUTION FUNCTION.

Let

$$M(\alpha) \equiv \max_{\{} j : \alpha_j > 0\}, \tag{6}$$

i.e., the length of the longest cycle in Π. Then Golomb (1959) derived

$$\lambda \equiv \lim_{n\to\infty} \frac{\langle M(\alpha)\rangle}{n} = 0.6243299885\ldots, \tag{7}$$

which is known as the GOLOMB CONSTANT or Golomb-Dickman constant. Knuth (1981) asked for the constants b and c such that

$$\lim_{n\to\infty} n^b \left[\langle M(\alpha)\rangle - \lambda n - \tfrac{1}{2}\lambda\right] = c, \tag{8}$$

and Gourdon (1996) showed that

$$\langle M(\alpha)\rangle = \lambda(n + \tfrac{1}{2}) - \frac{e^{\gamma}}{24n} + \frac{\frac{1}{48}e^{\gamma} - \frac{1}{8}(-1)^n}{n^2} + \frac{\frac{17}{3840}e^{\gamma} + \frac{1}{8}(-1)^n + \frac{1}{6}j^{1+2n} + \frac{1}{6}j^{2+n}}{n^3}, \tag{9}$$

where

$$j \equiv e^{2\pi i/3}. \tag{10}$$

λ can be expressed in terms of the function $f(x)$ defined by $f(x) = 1$ for $1 \le x \le 2$ and

$$\frac{df}{dx} = -\frac{f(x-1)}{x-1} \tag{11}$$

for $x > 2$, by

$$\lambda = \int_1^\infty \frac{f(x)}{x^2}\,dx. \tag{12}$$

Shepp and Lloyd (1966) derived

$$\lambda = \int_0^\infty \exp\left(-x - \int_x^\infty \frac{e^{-y}}{y}\,dy\right)$$
$$= \int_0^1 \exp\left(\int_0^x \frac{dy}{\ln y}\right) dx. \tag{13}$$

Mitchell (1968) computed λ to 53 decimal places.

Surprisingly enough, there is a connection between λ and PRIME FACTORIZATION (Knuth and Pardo 1976, Knuth 1981, pp. 367–68, 395, and 611). Dickman (1930) investigated the probability $P(x, n)$ that the largest PRIME FACTOR p of a random INTEGER between 1 and n satisfies $p < n^x$ for $x \in (0, 1)$. He found that

$$F(x) \equiv \lim_{n\to\infty} P(x, n) = \begin{cases} 1 & \text{if } x \geq 1 \\ \int_0^x F\left(\frac{t}{1-t}\right)\frac{dt}{t} & \text{if } 0 \leq x \leq 1. \end{cases} \tag{14}$$

Dickman then found the average value of x such that $p = n^x$, obtaining

$$\mu \equiv \lim_{n\to\infty}\langle x\rangle = \lim_{n\to\infty}\left\langle\frac{\ln p}{\ln n}\right\rangle = \int_0^1 x\,\frac{dF}{dx}\,dx$$
$$= \int_0^1 F\left(\frac{1}{1-t}\right) dt = 0.62432999, \tag{15}$$

which is λ.

Golygon

A PLANE path on a set of equally spaced LATTICE POINTS, starting at the ORIGIN, where the first step is one unit to the north or south, the second step is two units to the east or west, the third is three units to the north or south, etc., and continuing until the ORIGIN is again reached. No crossing or backtracking is allowed. The simplest golygon is (0, 0), (0, 1), (2, 1), (2, −2), (−2, −2), (−2, −7), (−8, −7), (−8, 0), (0, 0). A golygon can be formed if there exists an EVEN INTEGER n such that

$$\pm 1 \pm 3 \pm \ldots \pm (n-1) = 0 \tag{1}$$

$$\pm 2 \pm 4 \pm \ldots \pm n = 0 \tag{2}$$

(Vardi 1991). Gardner proved that all golygons are OF THE FORM $n = 8k$. The number of golygons of length n (EVEN), with each initial direction counted separately, is the PRODUCT of the COEFFICIENT of $x^{n^2/8}$ in

$$(1+x)(1+x^3)\cdots(1+x^{n-1}), \tag{3}$$

with the COEFFICIENT of $x^{n(n/2+1)/8}$ in

$$(1+x)(1+x^2)\cdots(1+x^{n/2}). \tag{4}$$

The number of golygons $N(n)$ of length $8n$ for the first few n are 4, 112, 8432, 909288, ... (Sloane's A006718) and is asymptotic to

$$N(n) \sim \frac{3 \cdot 2^{8n-4}}{\pi n^2(4n+1)} \tag{5}$$

(Sallows *et al.* 1991, Vardi 1991).

Gomory's Theorem

Regardless of where one white and one black square are deleted from an ordinary 8×8 CHESSBOARD, the reduced board can always be covered exactly with 31 DOMINOES (of dimension 2×1).

See also CHESSBOARD

Gompertz Constant

$$G\equiv\int_0^\infty \frac{e^{-u}}{1+u}\,du=-e\ \mathrm{ei}(-1)$$
$$=0.596347362\ldots,$$

where $\mathrm{ei}(x)$ is the EXPONENTIAL INTEGRAL. Stieltjes showed it has the CONTINUED FRACTION representation

$$G=\frac{1}{2-}\ \frac{1^2}{4-}\ \frac{2^2}{6-}\ \frac{3^2}{8-}\ \cdots.$$

Gompertz Curve

The function defined by

$$y=ab^{q^x}.$$

It is used in actuarial science for specifying a simplified mortality law (Kenney and Keeping 1962, p. 241). Using $s(x)$ as the probability that a newborn will achieve age x, the Gompertz law is

$$s(x)=\exp[-m(c^x-1)],$$

for $c>1$, $x\geq 0$ (Gompertz 1832).

Gon

GRADIAN

Gonal Number

POLYGONAL NUMBER

Good Binomial Coefficient

A BINOMIAL COEFFICIENT $\binom{N}{k}$ with $k\geq 2$ is called good if its LEAST PRIME FACTOR satisfies

$$\mathrm{lpf}\binom{N}{k}>k$$

(Erdos*et al.* 1993). This is equivalent to the requirement that

$$\mathrm{GCD}\left(\binom{N}{k},\ k!\right)=1.$$

The first few good binomial coefficients are therefore $\binom{3}{2}$, $\binom{5}{4}$, $\binom{6}{2}$, $\binom{7}{2}$, $\binom{7}{3}$, $\binom{7}{4}$, $\binom{7}{6}$, $\binom{10}{2}$, ... Good binomial coefficients are closely related to the ERDOS-SELFRIDGE FUNCTION $g(k)$, which gives the least integer $N>k+1$ such that $\binom{N}{k}$ is good.

See also BINOMIAL COEFFICIENT, DEFICIENCY, ERDOS-SELFRIDGE FUNCTION, EXCEPTIONAL BINOMIAL COEFFICIENT

Good Path

p-GOOD PATH

Good Prime

A PRIME p_n is called "good" if

$$p_n^2>p_{n-i}p_{n+i}$$

for all $1\leq i\leq n-1$ (there is a typo in Guy 1994 in which the is are replaced by 1s). There are infinitely many good primes, and the first few are 5, 11, 17, 29, 37, 41, 53, ... (Sloane's A028388).

Goodman's Formula

A two-coloring of a COMPLETE GRAPH K_n of n nodes which contains exactly the number of MONOCHRO-

MATIC FORCED TRIANGLES and no more (i.e., a minimum of $R+B$ where R and B are the number of red and blue TRIANGLES) is called an EXTREMAL GRAPH. Goodman (1959) showed that for an extremal graph,

$$R+B=\begin{cases}\frac{1}{3}m(m-1)(m-2) & \text{for } n=2m\\ \frac{2}{3}m(m-1)(4m+1) & \text{for } n=4m+1\\ \frac{2}{3}m(m+1)(4m-1) & \text{for } n=4m+3.\end{cases}$$

Schwenk (1972) rewrote the equation in the form

$$R+B=\binom{n}{3}-\left\lfloor\tfrac{1}{2}n\left\lfloor\tfrac{1}{4}(n-1)^2\right\rfloor\right\rfloor,$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $\lfloor x\rfloor$ is the FLOOR FUNCTION.

Goodstein Sequence

Given a HEREDITARY REPRESENTATION of a number n in BASE b, let $B[b](n)$ be the NONNEGATIVE INTEGER which results if we syntactically replace each b by $b+1$ (i.e., $B[b]$ is a base change operator that 'bumps the base' from b up to $b+1$). The HEREDITARY REPRESENTATION of 266 in base 2 is

$$266=2^8+2^3+2$$
$$=2^{2^{2+1}}+2^{2+1}+2,$$

so bumping the base from 2 to 3 yields

$$B[2](266)=3^{3^{3+1}}+3^{3+1}+3.$$

Now repeatedly bump the base and subtract 1,

$$G_0(266)=266=2^{2^{2+1}}+2^{2+1}+2$$
$$G_1(266)=B[2](266)-1=3^{3^{3+1}}+3^{3+1}+2$$
$$G_2(266)=B[3](G_1)-1=4^{4^{4+1}}+4^{4+1}+1$$
$$G_3(266)=B[4](G_2)-1=5^{5^{5+1}}+5^{5+1}+1$$
$$G_4(266)=B[5](G_3)-1=6^{6^{6+1}}+6^{6+1}-1$$
$$=6^{6^{6+1}}+5\cdot 6^6+5\cdot 6^5+\ldots+5\cdot 6+5$$
$$G_5(266)=B[6](G_4)-1$$
$$=7^{7^{7+1}}+5\cdot 7^7+5\cdot 7^5+\ldots+5\cdot 7+4,$$

etc. Starting this procedure at an INTEGER n gives the Goodstein sequence $\{G_k(n)\}$. Amazingly, despite the apparent rapid increase in the terms of the sequence, GOODSTEIN'S THEOREM states that $G_k(n)$ is 0 for any n and any sufficiently large k.

Goodstein's Theorem

For all n, there exists a k such that the kth term of the GOODSTEIN SEQUENCE $G_k(n)=0$. In other words, every GOODSTEIN SEQUENCE converges to 0.

The secret underlying Goodstein's theorem is that the HEREDITARY REPRESENTATION of n in base b mimics an ordinal notation for ordinals less than some number. For such ordinals, the base bumping operation leaves the ordinal fixed whereas the subtraction of one decreases the ordinal. But these ordinals are well ordered, and this allows us to conclude that a Goodstein sequence eventually converges to zero.

Goodstein's theorem cannot be proved in PEANO ARITHMETIC (i.e., formal NUMBER THEORY).

Gordon Matrix

PRIME ARRAY

Gordon-Luecke Theorem

Two distinct knots cannot have the same exterior. Or, equivalently, a knot is completely determined by its KNOT EXTERIOR (Adams 1994, p. 261). The question was first posed by Tietze in 1908, and finally proved by Gordon and Luecke (1989).

See also KNOT EXTERIOR

Gosper's Algorithm

An ALGORITHM for finding closed form HYPERGEOMETRIC IDENTITIES. The algorithm treats sums whose successive terms have ratios which are RATIONAL FUNCTIONS. Not only does it decide conclusively whether there exists a hypergeometric sequence z_n such that

$$t_n = z_{n+1} - z_n, \tag{1}$$

but actually produces z_n if it exists. If not, it produces $\Sigma_{k=0}^{n-1} t_k$. An outline of the algorithm follows (Petkovsek 1996):

1. For the ratio $r(n) = t_{n+1}/t_n$ which is a RATIONAL FUNCTION of n.
2. Write

$$r(n) = \frac{a(n)}{b(n)} \frac{c(n+1)}{c(n)}, \quad (2)$$

where $a(n)$, $b(n)$, and $c(n)$ are polynomials satisfying

$$\mathrm{GCD}(a(n),\ b(n+h)) = 1 \quad (3)$$

for all nonnegative integers h.
3. Find a nonzero polynomial solution $x(n)$ of

$$a(n)x(n+1) - b(n-1)x(n) = c(n), \quad (4)$$

if one exists.
4. Return $b(n-1)x(n)/c(n)t_n$ and stop.

Petkovsek *et al.* (1996) describe the algorithm as "one of the landmarks in the history of computerization of the problem of closed form summation." Gosper's algorithm is vital in the operation of ZEILBERGER'S ALGORITHM and the machinery of WILF-ZEILBERGER PAIRS.

Gosper's Method

GOSPER'S ALGORITHM

Gossip Problem

GOSSIPING

Gossiping

This entry contributed by RONALD M. AARTS

Gossiping and broadcasting are two problems of information dissemination described for a group of individuals connected by a communication network. In gossiping, every person in the network knows a unique item of information and needs to communicate it to everyone else. In broadcasting, one individual has an item of information which needs to be communicated to everyone else (Hedetniemi *et al.* 1988).

A popular formulation assumes there are n people, each one of whom knows a scandal which is not known to any of the others. They communicate by telephone, and whenever two people place a call, they pass on to each other as many scandals as they know. How many calls are needed before everyone knows about all the scandals? Denoting the scandal-spreaders as A, B, C, and D, a solution for $n = 4$ is given by $\{A,\ B\}$, $\{C,\ D\}$, $\{A,\ C\}$, $\{B,\ D\}$. The $n = 4$ solution can then be generalized to $n > 4$ by adding the pair $\{A,\ X\}$ to the beginning and end of the previous solution, i.e., $\{A,\ E\}$, $\{A,\ B\}$, $\{C,\ D\}$, $\{A,\ C\}$, $\{B,\ D\}$, $\{A,\ E\}$.

Gossiping (which is also called total exchange or all-to-all communication) was originally introduced in discrete mathematics as a combinatorial problem in GRAPH THEORY, but it also has applications in communications and distributed memory multiprocessor systems (Bermond *et al.* 1998). Moreover, the gossip problem is implicit in a large class of parallel computation problems, such as linear system solving, the DISCRETE FOURIER TRANSFORM, and SORTING. Surveys are given in Hedetniemi *et al.* (1988) and Hromkovic *et al.* (1995).

Let $f(n)$ be the number of minimum calls necessary to complete gossiping among n people, where any pair of people may call each other. Then $f(1) = 0$, $f(2) = 1$, $f(3) = 3$, and

$$f(n) = 2n - 4$$

for $n \geq 4$. This result was proved by (Tijdeman 1971), as well as many others.

In the case of one-way communication ("polarized telephones"), e.g., where communication is done by letters or telegrams, the graph becomes a DIRECTED GRAPH and the minimum number of calls becomes

$$f(n) = 2n - 2$$

for $n \geq 4$ (Harary and Schwenk 1974).

Gould and Hsu Matrix Inversion Formula

Let (a_i) be a sequence of complex numbers and let the LOWER TRIANGULAR MATRICES $F=(F(n,\ k))$ and $G=(G(n,\ k))$ be defined as

$$F(n,\ k)=\frac{\prod_{j=k}^{n-1}(a_j+k)}{(n-k)!}$$

and

$$G(n,\ k)=(-1)^{n-k}\ \frac{a_k+k}{a_n+n}\ \frac{\prod_{j=k+1}^{n}(a_j+n)}{(n-k)!},$$

where the product over an EMPTY SET is 1. Then F and G are MATRIX INVERSES (Bhatnagar 1995, pp. 15–6 and 50–1). The KRATTENTHALER MATRIX INVERSION FORMULA is a generalization of this result.

See also KRATTENTHALER MATRIX INVERSION FORMULA

Gould Polynomial

The polynomials $G_n(x;\ a,\ b)$ given by the associated SHEFFER SEQUENCE with

$$f(t)=e^{at}(e^{bt}-1),$$

where $b\neq 0$. The INVERSE FUNCTION (and therefore GENERATING FUNCTION) cannot be computed algebraically, but the GENERATING FUNCTION

$$\sum_{k=0}^{\infty}\frac{G_k(x;\ a,\ b)}{k!}\ t^k=e^{xf^{-1}(t)} \tag{1}$$

can be given in terms of the sum

$$f^{-1}(t)=\sum_{k=1}^{\infty}\frac{1}{b}\binom{-(b+ak)/b}{k-1}\frac{t^k}{k}. \tag{2}$$

This results in

$$G_n(x;\ a,\ b)=\frac{x}{x-an}\left(\frac{x-an}{b}\right)_n$$

where $(x)_n$ is a FALLING FACTORIAL. The first few are

$$G_0(x;\ a,\ b)=1$$
$$G_1(x;\ a,\ b)=\frac{x}{b}$$
$$G_2(x;\ a,b)=-\frac{(2a+b-x)}{b^2}$$
$$G_3(x;\ a,\ b)=\frac{(3a+b-x)(3a+2b-x)x}{b^3}$$

$$G_4(x;\ a,b)$$
$$=-\frac{(4a+b-x)(4a+2b-x)(4a+3b-x)x}{b^4}.$$

The binomial identity obtained from the SHEFFER SEQUENCE gives the generalized CHU-VANDERMONDE IDENTITY

$$\frac{x+y}{x+y-an}\binom{(x+y-an)/b}{n}$$
$$=\sum_{k=0}^{n}\frac{x}{x-ak}\ \frac{y}{y-a(n-k)}\binom{\frac{x-ak}{b}}{k}\binom{\frac{y-a(n-k)}{a}}{n-k} \tag{3}$$

(Roman 1984, p. 69).

In the special case $a=-b/2$, the function $f(t)$ simplifies to

$$f(t)=e^{bt/2}-e^{-bt/2}=2\sinh(\tfrac{1}{2}bt), \tag{4}$$

which gives the GENERATING FUNCTION

$$\sum_{k=0}^{\infty}\frac{G_k(x;\ -\frac{1}{2}b,\ b)}{k!}\ t^k=\exp\left[\frac{2x\sinh^{-1}(\frac{1}{2}t)}{b}\right], \tag{5}$$

giving the polynomials

$$G_0(x;\ -b/2,\ b)=1$$
$$G_1(x;\ -b/2,\ b)=\frac{x}{b}$$
$$G_2(x;\ -b/2,\ b)=\frac{x^2}{b^2}$$
$$G_3(x;\ -b/2,\ b)=-\frac{(b-2x)x(b+2x)}{4b^3}$$
$$G_4(x;\ -b/2,\ b)=-\frac{(b-x)x^2(b+x)}{b^4}.$$

Goursat Problem

For the HYPERBOLIC PARTIAL DIFFERENTIAL EQUATION

$$u_{xy} = F(x,\ y,\ u,\ p,\ q) \tag{1}$$

$$p = u_x \tag{2}$$

$$q = u_y \tag{3}$$

on a domain Ω, Goursat's problem asks to find a solution $u(x,\ y)$ of (3) from the BOUNDARY CONDITIONS

$$u(0,\ t) = \phi(t) \tag{4}$$

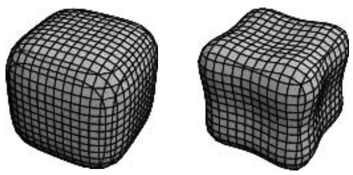
$$u(t,\ 1) = \psi(t) \tag{5}$$

$$\phi(1) = \phi(0) \tag{6}$$

for $0 \leq t \leq 1$ that is regular in Ω and continuous in the closure $\bar{\Omega}$, where ϕ and ψ are specified continuously differentiable functions.

The linear Goursat problem corresponds to the solution of the equation

$$\tilde{L}u = u_{xy} + au_x + bu_y + cu = f, \tag{7}$$



which can be effected using the so-called RIEMANN FUNCTION $R(x,\ y;\ \xi,\ \eta)$. The use of the RIEMANN FUNCTION to solve the linear Goursat problem is called the RIEMANN METHOD.

Goursat's Surface

A general QUARTIC SURFACE defined by

$$x^4 + y^4 + z^4 + a(x^2 + y^2 + z^2)^2 + b(x^2 + y^2 + z^2) + c$$

(Gray 1997, p. 314). The above two images correspond to $a = b = 0$, $c = -1$, and $a = 0$, $b = -2$, $c = -1$, respectively.

The related surface

$$x^n + y^n + z^n = 1$$

for $n \geq 2$ an even integer is considered by Gray (1997, p. 292), and might appropriately be called a SUPERELLIPSOID.

Graceful Graph

A LABELED GRAPH which can be "gracefully numbered" is called a graceful graph. Label the nodes with distinct NONNEGATIVE INTEGERS. Then label the EDGES with the absolute differences between node values. If the EDGE numbers then run from 1 to e, the graph is gracefully numbered. In order for a graph to be graceful, it must be without loops or multiple EDGES.

Golomb showed that the number of EDGES connecting the EVEN-numbered and ODD-numbered sets of nodes is $\lfloor (e+1/)2 \rfloor$, where e is the number of EDGES. In addition, if the nodes of a graph are all of EVEN ORDER, then the graph is graceful only if $\lfloor (e+1/)2 \rfloor$ is EVEN. The only ungraceful simple graphs with ≤ 5 nodes are shown below.

There are exactly $e!$ graceful graphs with e EDGES (Sheppard 1976), where $e!/2$ of these correspond to different labelings of the same graph. Golomb (1974) showed that all complete bipartite graphs are graceful. CATERPILLAR GRAPHS; COMPLETE GRAPHS K_2, K_3, $K_4 = W_4 = T$ (and only these; Golomb 1974); CYCLIC GRAPHS C_n when $n \equiv 0$ or 3(mod 4), when the number of consecutive chords $k = 2$, 3, or $n-3$ (Koh and Punnim 1982), or when they contain a P_k chord (Delorme *et al.* 1980, Koh and Yap 1985, Punnim and Pabhapote 1987); GEAR GRAPHS; PATH GRAPHS; the PETERSEN GRAPH; POLYHEDRAL GRAPHS $T = K_4 = W_4$, C, O, D, and I (Gardner 1983); STAR GRAPHS; the THOMSEN GRAPH (Gardner 1983); and WHEEL GRAPHS (Frucht 1988) are all graceful.

Some graceful graphs have only one numbering, but others have more than one. It is conjectured that all trees are graceful (Bondy and Murty 1976), but this has only been proved for trees with ≤ 16 VERTICES. It has also been conjectured that all unicyclic graphs are graceful.

Graceful Permutation

A graceful permutation σ on n letters is a PERMUTATION such that

$$\{|\sigma(i)-\sigma(i+1)| : i=1, 2, \ldots, n-1\} = \{1, 2, \ldots, n-1\}.$$

For example, there are four graceful permutations on $\{1,2,3,4\}$: $\{1,4,2,3\}$, $\{2,3,1,4\}$, $\{3,2,4,1\}$, and $\{4,1,3,2\}$. The number of graceful permutations on n letters for n = 1, 2, ... are 1, 2, 4, 4, 8, 24, 32, 40, ... (Sloane's A006967).

Grade

GRADIAN

Graded Algebra

If A is a GRADED MODULE and there EXISTS a degree-preserving linear map $\phi : A \otimes A \to A$, then (A, ϕ) is called a graded algebra.

COHOMOLOGY is a graded algebra. In addition, the GRADING SET is MONOID having a compatibility relation such that if A is in the a grading of the algebra M, and B is in the b grading of the algebra M, then AB is in the ab grading of the algebra (where A and B are multiplied in M, and a and b are multiplied in the index monoid). For example, cohomology of a space is a graded algebra over the integers (i.e., a GRADED RING), since if A is an n-dimensional cohomology class and B is an m-dimensional cohomology class, then the CUP PRODUCT AB is an $m+n$ dimensional cohomology class.

The GROUP RING of a GROUP G over a RING R is a graded R-algebra with grading G.

See also COHOMOLOGY, GRADED MODULE, GRADED RING, GROUP RING

References

Jacobson, N. *Lie Algebras.* New York: Dover, p. 163, 1979.

Graded Module

A decomposition of a MODULE into a DIRECT SUM of SUBMODULES. The INDEX SET for the collection of SUBMODULES is then called the GRADING SET.

Graded modules arise naturally in HOMOLOGY. In particular, for every integer i, there exists an ith HOMOLOGY GROUP of a space $H_i(X)$, and usually the "total homology" of the space is considered to be the direct sum of all the $H_i(X)$s. This makes the "total" homology of X a module graded over the integers.

See also GRADED ALGEBRA

Graded Ring

A GRADED ALGEBRA over the integers $\mathbb{Z}$. COHOMOLOGY of a space is a graded ring.

See also GRADED ALGEBRA

Gradian

A unit of angular measure in which the angle of an entire CIRCLE is 400 gradians. A RIGHT ANGLE is therefore 100 gradians. A gradian is sometimes also called a GON or a GRADE.

See also DEGREE, RADIAN

References

Harris, J. W. and Stocker, H. *Handbook of Mathematics and Computational Science.* New York: Springer-Verlag, p. 63, 1998.

Gradient

The gradient is a VECTOR operator denoted ∇ and sometimes also called DEL or NABLA. It is most often applied to a real function of three variables $f(u_1, u_2, u_3)$, and may be denoted

$$\nabla f \equiv \mathrm{grad(f)}. \qquad (1)$$

For general CURVILINEAR COORDINATES, the gradient is given by

$$\nabla\phi = \frac{1}{h_1}\frac{\partial\phi}{\partial u_1}\,\hat{\mathbf{u}}_1 + \frac{1}{h_2}\frac{\partial\phi}{\partial u_2}\,\hat{\mathbf{u}}_2 + \frac{1}{h_3}\frac{\partial\phi}{\partial u_3}\,\hat{\mathbf{u}}_3, \qquad (2)$$

which simplifies to

$$\nabla\phi(x, y, z) = \frac{\partial\phi}{\partial x}\hat{\mathbf{x}} + \frac{\partial\phi}{\partial y}\hat{\mathbf{y}} + \frac{\partial\phi}{\partial z}\hat{\mathbf{z}} \tag{3}$$

in CARTESIAN COORDINATES.

The direction of ∇f is the orientation in which the DIRECTIONAL DERIVATIVE has the largest value and $|\nabla f|$ is the value of that DIRECTIONAL DERIVATIVE. Furthermore, if $\nabla f \neq 0$, then the gradient is PERPENDICULAR to the LEVEL CURVE through (x_0, y_0) if $z = f(x, y)$ and PERPENDICULAR to the level surface through (x_0, y_0, z_0) if $F(x, y, z) = 0$.

In TENSOR notation, let

$$ds^2 = g_\mu \, dx_\mu^2 \tag{4}$$

be the LINE ELEMENT in principal form. Then

$$\nabla_{\vec{e}_\alpha}\vec{e}_\beta = \nabla_\alpha \vec{e}_\beta = \frac{1}{\sqrt{g\alpha}} \frac{\partial}{\partial x_\alpha} \vec{e}_\beta. \tag{5}$$

For a MATRIX A,

$$\nabla|\mathsf{A}\mathbf{x}| = \frac{(\mathsf{A}\mathbf{x})^{\mathrm{T}}\mathsf{A}}{|\mathsf{A}\mathbf{x}|}. \tag{6}$$

For expressions giving the gradient in particular coordinate systems, see CURVILINEAR COORDINATES.

Gradient Descent Method

STEEPEST DESCENT METHOD

Gradient Four-Vector

The 4-dimensional version of the GRADIENT, encountered frequently in general relativity and special relativity, is

$$\nabla_\mu = \begin{bmatrix} \frac{1}{c}\frac{\partial}{\partial t} \\ \frac{\partial}{\partial x} \\ \frac{\partial}{\partial y} \\ \frac{\partial}{\partial z} \end{bmatrix},$$

which can be written

$$(\nabla^\mu)^2 \equiv \Box^2,$$

where $\Box^2$ is the D'ALEMBERTIAN.

Gradient Theorem

$$\int_b^a (\nabla f) \cdot ds = f(b) - f(a),$$

where ∇ is the GRADIENT, and the integral is a LINE INTEGRAL. It is this relationship which makes the definition of a scalar potential function f so useful in gravitation and electromagnetism as a concise way to encode information about a VECTOR FIELD.

EULER SQUARE

Graeffe Iteration

GRAEFFE'S METHOD

Graeffe's Method

A ROOT-finding method which was among the most popular methods for finding roots of UNIVARIATE POLYNOMIALS in the 19th and 20th centuries. It was invented independently by Graeffe, dandelin, and Lobachevsky (Householder 1959, Malajovich and Zubelli 1999). Graeffe's method has a number of drawbacks, among which are that its usual formulation leads to exponents exceeding the maximum allowed by floating-point arithmetic and also that it can map well-conditioned polynomials into ill-conditioned ones. However, these limitations are avoided in an efficient implementation by Malajovich and Zubelli (1999).

The method proceeds by multiplying a POLYNOMIAL $f(x)$ by $f(-x)$ and noting that

$$f(x) = (x - a_1)(x - a_2)\cdots(x - a_n) \tag{1}$$

$$f(-x) = (-1)^n (x + a_1)(x + a_2)\cdots(x + a_n) \tag{2}$$

so the result is

$$f(x)f(-x) = (-1)^n (x^2 - a_1^2)(x^2 - a_2^2)\cdots(x^2 - a_n^2). \tag{3}$$

repeat ν times, then write this in the form

$$y^n + b_1 y^{n-1} + \ldots + b_n = 0 \quad (4)$$

where $y \equiv x^{2^v}$. Since the coefficients are given by NEWTON'S RELATIONS

$$b_1 = -(y_1 + y_2 + \ldots + y_n) \quad (5)$$

$$b_2 = (y_1 y_2 + y_1 y_3 + \ldots + y_{n-1} y_n) \quad (6)$$

$$b_n = (-1)^n y_1 y_2 \cdots y_n, \quad (7)$$

and since the squaring procedure has separated the roots, the first term is larger than rest. Therefore,

$$b_1 \approx -y_1 \quad (8)$$

$$b_2 \approx y_1 y_2 \quad (9)$$

$$b_n \approx (-1)^n y_1 y_2 \cdots y_n, \quad (10)$$

giving

$$y_1 \approx -b_1 \quad (11)$$

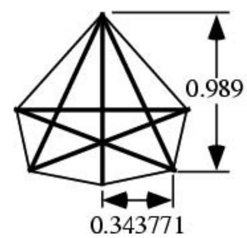
$$y_2 \approx -\frac{b_2}{b_1} \quad (12)$$

$$y_n \approx -\frac{b_n}{b_{n-1}}. \quad (13)$$

Solving for the original roots gives

$$a_1 \approx \sqrt{-b_1} \quad (14)$$

$$a_2 \approx \sqrt{-\frac{b_2}{b_1}} \quad (15)$$



$$a_n \approx \sqrt{-\frac{b_n}{b_{n-1}}}. \quad (16)$$

This method works especially well if all roots are real.

Graham's Biggest Little Hexagon

The largest possible (not necessarily regular) HEXAGON for which no two of the corners are more than unit distance apart. In the above figure, the heavy lines are all of unit length. The AREA of the hexagon is $A = 0.674981\ldots$, where A is the second-largest real ROOT of

$$\begin{aligned} &4096A^{10} + 8192A^9 - 3008A^8 - 30,848A^7 + 21,056A^6 \\ &\quad + 146,496A^5 - 221,360A^4 + 1232A^3 + 144,464A^2 \\ &\quad - 78,488A + 11,993 \\ &= 0. \end{aligned}$$

Note that the sign of the A^9 is positive, not negative as erroneously given in Conway and Guy (1996).

Graham's Number

The smallest dimension n of a HYPERCUBE such that if the lines joining all pairs of corners are two-colored, a PLANAR COMPLETE GRAPH K_4 of one color will be forced. Stated colloquially, this is equivalent to considering every possible committee from some number of people n and enumerating every pair of committees. Now assign each pair of committees to one of two groups, and find the smallest n that will guarantee that there are four committees in which all pairs fall in the same group and all the people belong to an even number of committees (Hoffman 1998, p. 54).

An answer was proved to exist by R. L. Graham and B. L. Rothschild. However, although the actual answer is believed to be 6, the best bound proved is

$$64\left\{\begin{array}{l}\underbrace{3\uparrow\uparrow\uparrow\uparrow 3}\\ \underbrace{3\uparrow 3}\\ \underbrace{\vdots}\\ 3\uparrow 3\end{array}\right.$$

where $\uparrow$ is stacked ARROW NOTATION. It is less than $3 \to 3 \to 3 \to 3$, where CHAINED ARROW NOTATION has been used.

Gram Determinant

The DETERMINANT

$$G(f_1, f_2, \ldots, f_n) = \begin{vmatrix} \int f_1^2\,dt & \int f_1 f_2\,dt & \cdots & \int f_1 f_n\,dt \\ \int f_2 f_1\,dt & \int f_2^2\,dt & \cdots & \int f_2 f_n\,dt \\ \vdots & \vdots & \ddots & \vdots \\ \int f_1 f_n\,dt & \int f_1 f_n\,dt & \cdots & \int f_n^2\,dt \end{vmatrix}.$$

Gram Matrix

Given m points with n-D vector coordinates $\mathbf{v}_i$, let M be the $n \times m$ matrix whose jth column consists of the coordinates of the vector $\mathbf{v}_j$, with $j = 1, \ldots, m$. Then define the $m \times m$ Gram matrix of dot products $a_{ij} = \mathbf{v}_i \cdot \mathbf{v}_j$ as

$$\mathsf{A} = \mathsf{M}^{\mathrm{T}}\mathsf{M},$$

where A^{T} denotes the TRANSPOSE. The Gram matrix determines the vectors $\mathbf{v}_i$ up to ISOMETRY.

Gram Series

$$G(x) = 1 + \sum_{k=1}^{\infty} \frac{(\ln x)^k}{k k! \zeta(k+1)},$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Hardy 1999, p. 24). This approximation to the PRIME COUNTING FUNCTION is 10 times better than $\mathrm{Li}(x)$ for $x < 10^9$ but has been proven to be worse infinitely often by Littlewood (Ingham 1990). An equivalent formulation due to Ramanujan is

$$G(x) \equiv \frac{4}{\pi} \sum_{k=1}^{\infty} \frac{(-1)^{k-1} k}{B_{2k}(2k-1)} \left(\frac{\ln x}{2\pi}\right)^{2k-1} \sim \pi(x)$$

(Berndt 1994; Hardy 1999, p. 23), where B_{2k} is a BERNOULLI NUMBER. The integral analog, also found by Ramanujan, is

$$J(x) \equiv \int_0^{\infty} \frac{(\ln x)^t\,dt}{t\Gamma(t+1)\zeta(t+1)} \sim \pi(x)$$

(Berndt 1994; Hardy 1999, p. 23).

The Gram series is equivalent to the RIEMANN PRIME NUMBER FORMULA (Hardy 1999, pp. 24–5).

Gram's Inequality

Let $f_1(x), \ldots, f_n(x)$ be REAL INTEGRABLE FUNCTIONS over the CLOSED INTERVAL $[a, b]$, then the DETERMINANT of their integrals satisfies

$$\begin{vmatrix} \int_a^b f_1^2(x)\,dx & \int_a^b f_1(x)f_2(x)\,dx & \cdots & \int_a^b f_1(x)f_n(x)\,dx \\ \int_a^b f_2(x)f_1(x)\,dx & \int_a^b f_2^2(x)\,dx & \cdots & \int_a^b f_2(x)f_n(x)\,dx \\ \vdots & \vdots & \ddots & \vdots \\ \int_a^b f_n(x)f_1(x)\,dx & \int_a^b f_n(x)f_2(x)\,dx & \cdots & \int_a^b f_n(x)f_n(x)\,dx \end{vmatrix} \geq 0.$$

Gram-Charlier Series

EDGEWORTH SERIES

Gram-Schmidt Orthonormalization

A procedure which takes a nonorthogonal set of LINEARLY INDEPENDENT functions and constructs an ORTHOGONAL BASIS over an arbitrary interval with respect to an arbitrary WEIGHTING FUNCTION $w(x)$.

Given an original set of linearly independent functions $\{u_n\}_{n=0}^{\infty}$, let $\{\psi_n\}_{n=0}^{\infty}$ denote the orthogonalized (but not normalized) functions, $\{\phi_n\}_{n=0}^{\infty}$ denote the orthonormalized functions, and define

$$\psi_0(x) \equiv u_0(x) \tag{1}$$

$$\phi_0(x) \equiv \frac{\psi_0(x)}{\sqrt{\int \psi_0^2(x)w(x)\,dx}}. \tag{2}$$

Then take

$$\psi_1(x) = u_1(x) + a_{10}\phi_0(x), \tag{3}$$

where we require

$$\int \psi_1\phi_0 w\,dx = \int u_1\phi_0 w\,dx + a_{10}\int \phi_0^2 w\,dx = 0. \tag{4}$$

By definition,

$$\int \phi_0^2 w\,dx = 1, \tag{5}$$

so

$$a_{10} = -\int u_1\phi_0 w\,dx. \tag{6}$$

The first orthogonalized function is therefore

$$\psi_1 = u_1(x) - \left[\int u_1\phi_0 w\,dx\right]\phi_0, \tag{7}$$

and the corresponding normalized function is

$$\phi_1 = \frac{\psi_1(x)}{\sqrt{\int \psi_1^2 w\,dx}}. \tag{8}$$

By mathematical induction, it follows that

$$\phi_i(x) = \frac{\psi_i(x)}{\sqrt{\int \psi_i^2 w\,dx}}, \tag{9}$$

where

$$\psi_i(x) = u_i + a_{i0}\phi_0 + a_{i1}\phi_1 \ldots + a_{i,\,i-1}\phi_{i-1} \tag{10}$$

and

$$a_{ij} \equiv -\int u_i\phi_j w\,dx. \tag{11}$$

If the functions are normalized to N_j instead of 1, then

$$\int_a^b [\phi_j(x)]^2 w\,dx = N_j^2 \tag{12}$$

$$\phi_i(x) = N_i \frac{\psi_i(x)}{\sqrt{\int \psi_i^2 w\,dx}} \tag{13}$$

$$a_{ij} = -\frac{\int u_i\phi_j w\,dx}{N_j^2}. \tag{14}$$

ORTHOGONAL POLYNOMIALS are especially easy to generate using GRAM-SCHMIDT ORTHONORMALIZATION. Use the notation

$$\langle x_i|x_j\rangle \equiv \langle x_i|w|x_j\rangle \equiv \int_a^b x_i(x)x_j(x)w(x)\,dx, \tag{15}$$

where $w(x)$ is a WEIGHTING FUNCTION, and define the first few POLYNOMIALS,

$$p_0(x) \equiv 1 \tag{16}$$

$$p_1(x) = \left[x - \frac{\langle xp_0|p_0\rangle}{\langle p_0|p_0\rangle}\right]p_0. \tag{17}$$

As defined, p_0 and p_1 are ORTHOGONAL POLYNOMIALS, as can be seen from

$$\begin{aligned}\langle p_0|p_1\rangle &= \left\langle \left[x - \frac{\langle xp_0|p_0\rangle}{\langle p_0|p_0\rangle}\right]p_0 \right\rangle = \langle xp_0\rangle - \frac{\langle xp_0|p_0\rangle}{\langle p_0|p_0\rangle}\langle p_0\rangle \\ &= \langle xp_0\rangle - \langle xp_0\rangle = 0. \end{aligned} \tag{18}$$

Now use the RECURRENCE RELATION

$$p_{i+1}(x) = \left[x - \frac{\langle xp_i|p_i\rangle}{\langle p_i|p_i\rangle}\right]p_i - \left[\frac{\langle p_i|p_i\rangle}{\langle p_{i-1}|p_{i-1}\rangle}\right]p_{i-1} \tag{19}$$

to construct all higher order POLYNOMIALS.

To verify that this procedure does indeed produce ORTHOGONAL POLYNOMIALS, examine

$$\begin{aligned}\langle p_{i+1}|p_i\rangle &= \left\langle \left[x-\frac{\langle xp_i|p_i\rangle}{\langle p_i|p_i\rangle}\right]p_i|p_i\right\rangle \\ &\quad -\left\langle \frac{\langle p_i|p_i\rangle}{\langle p_{i-1}|p_{i-1}\rangle}p_{i-1}|p_i\right\rangle \\ &= \langle xp_i|p_i\rangle-\frac{\langle xp_i|p_i\rangle}{\langle p_i|p_i\rangle}\langle p_i|p_i\rangle-\frac{\langle p_i|p_i\rangle}{\langle p_{i-1}|p_{i-1}\rangle} \\ &\quad \times\langle p_{i-1}|p_i\rangle \\ &= -\frac{\langle p_i|p_i\rangle}{\langle p_{i-1}|p_{i-1}\rangle}\langle p_{i-1}|p_i\rangle \\ &= -\frac{\langle p_i|p_i\rangle}{\langle p_{i-1}|p_{i-1}\rangle}\left[-\frac{\langle p_{i-1}|p_{j-1}\rangle}{\langle p_{j-2}|p_{j-2}\rangle}\langle p_{j-2}|p_{j-1}\rangle\right] \\ &= \ldots = (-1)^j\frac{\langle p_j|p_j\rangle}{\langle p_0|p_0\rangle}\langle p_0|p_1\rangle = 0, \qquad (20)\end{aligned}$$

since $\langle p_0|p_1\rangle = 0$. Therefore, all the POLYNOMIALS $p_i(x)$ are orthogonal.

Many common ORTHOGONAL POLYNOMIALS of mathematical physics can be generated in this manner. Unfortunately, the process turns out to be numerically unstable (Golub and van Loan 1989).

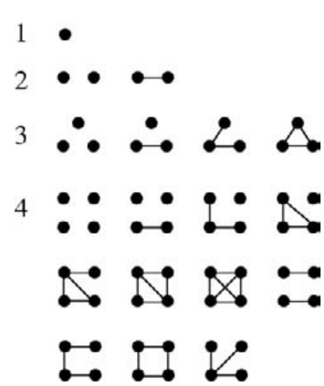
Granny Knot

A COMPOSITE KNOT of seven crossings consisting of a KNOT SUM of TREFOILS. The granny knot has the same ALEXANDER POLYNOMIAL $(x^2-x+1)^2$ as the SQUARE KNOT.



Graph

A mathematical object composed of points known as VERTICES or NODES and lines connecting some (possibly empty) SUBSET of them, known as EDGES. Formally, a graph is a binary relation on a set of vertices. If this relation is symmetric, the graph is said to be UNDIRECTED; otherwise, the graph is said to be DIRECTED. Graphs in which at most one edge connects any two nodes are said to be SIMPLE GRAPHS. Vertices are usually not allowed to be self-connected, but this restriction is sometimes relaxed to allow such "loops." The edges of a graph may be assigned specific values or labels, in which case the graph is called a LABELED GRAPH.

The study of graphs is known as GRAPH THEORY, and was first studied systematically by D. König in the 1930s (Gardner 1984, p. 91). As Gardner (1984, p. 91) notes, "The confusion of this term with the 'GRAPHS' of analytic geometry is regrettable, but the term has stuck."

Graphs are 1-D COMPLEXES, and there are always an EVEN NUMBER of ODD NODES in a graph. GRAPH SUMS, differences, powers, UNIONS, and PRODUCTS can be defined, as can GRAPH EIGENVALUES.

The number of nonisomorphic simple undirected

graphs with v NODES for $v = 1, 2, \ldots$, are 1, 2, 4, 11, 34, 156, 1044, ... (Sloane's A000088; see above figure). The PÓLYA ENUMERATION THEOREM can be used to determine these numbers. In order to apply the PÓLYA ENUMERATION THEOREM, define the quantity

$$h_j = \frac{p!}{\prod_{i=1}^{p} i^{j_i} j_i!}, \tag{1}$$

where $p!$ is the FACTORIAL of p, and the related polynomial

$$Z_p(S) = \sum_i h_{\mathbf{j}_i} \prod_{k=1}^{p} f_k^{(\mathbf{j}_i)_k}, \tag{2}$$

where the $\mathbf{j}_i = (j_1, \ldots, j_p)_i$ are all of the p-VECTORS satisfying

$$j_1 + 2j_2 + 3j_3 + \ldots + pj_p = p. \tag{3}$$

For example, for $p = 3$, the three possible values of $\mathbf{j}$ are

$$\mathbf{j}_1 = (3,0,0), \text{ since } (1 \cdot 3) + (2 \cdot 0) + (3 \cdot 0) = 3,$$

$$\text{giving } h_{\mathbf{j}_1} = \frac{3!}{(1^3 3!)(2^0 0!)(3^0 0!)} = 1 \tag{4}$$

$$\mathbf{j}_2 = (1,1,0), \text{ since } (1 \cdot 1) + (2 \cdot 1) + (3 \cdot 0) = 3,$$

$$\text{giving } h_{\mathbf{j}_2} = \frac{3!}{(1^1 1!)(2^1 1!)(3^0 0!)} = 3, \tag{5}$$

$$\mathbf{j}_3 = (0, 0, 1), \text{ since } (1 \cdot 0) + (2 \cdot 0) + (3 \cdot 1) = 3$$

$$\text{giving } h_{\mathbf{j}_3} = \frac{3!}{(1^0 0!)(2^0 0!)(3^1 1!)} = 2. \tag{6}$$

Therefore,

$$Z_3(S) = f_1^3 + 3f_1f_2 + 2f_3. \tag{7}$$

For small p, the first few values of $Z_p(S)$ are given by

$$Z_2(S) = f_1^2 + f_2 \tag{8}$$

$$Z_3(S) = f_1^3 + 3f_1f_2 + 2f_3 \tag{9}$$

$$Z_4(S) = f_1^4 + 6f_1^2f_2 + 3f_2^2 + 8f_1f_3 + 6f_4 \tag{10}$$

$$Z_5(S) = f_1^5 + 10f_1^3f_2 + 15f_1f_2^2 + 20f_1^2f_3 + 20f_2f_3 + 30f_1f_4 + 24f_5 \tag{11}$$

$$Z_6(S) = f_1^6 + 15f_1^4f_2 + 45f_1^2f_2^2 + 15f_2^3 + 40f_1^3f_3 + 120f_1f_2f_3 + 40f_3^2 + 90f_1^2f_4 + 90f_2f_4 + 144f_1f_5 + 120f_6 \tag{12}$$

$$Z_7(S) = f_1^7 + 21f_1^5f_2 + 105f_1^3f_2^2 + 105f_1f_2^3 + 70f_1^4f_3 + 420f_1^2f_2f_3 + 210f_2^2f_3 + 280f_1f_3^2 + 210f_1^3f_4 + 630f_1f_2f_4 + 420f_3f_4 + 504f_1^2f_5 + 504f_2f_5 + 840f_1f_6 + 720f_7. \tag{13}$$

Application of the PÓLYA ENUMERATION THEOREM then gives the formula

$$Z(R) = \frac{1}{p!} \sum_{(j)} h_{\mathrm{j}} \prod_{n=0}^{\lfloor (p-1)/2 \rfloor} g_{2n+1}^{nj_{2n+1} + (2n+1)\binom{j_{2n+1}}{2}} \times \prod_{n=1}^{\lfloor p/2 \rfloor} [(g_n g_{2n})^{n-1}]^{j_{2n}} g_{2n}^{2n\binom{j_{2n}}{2}} \times \prod_{q=1}^{p} \prod_{r=q+1}^{p} g_{\mathrm{LCM}(q,\,r)}^{j_q j_r \mathrm{GCD}(q,\,r)}, \tag{14}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, $\binom{n}{m}$ is a BINOMIAL COEFFICIENT, LCM is the LEAST COMMON MULTIPLE, GCD is the GREATEST COMMON DIVISOR, and the SUM (j) is over all $\mathbf{j}_i$ satisfying the sum identity described above. The first few generating functions $Z_p(R)$ are

$$Z_2(R) = 2g_1 \tag{15}$$

$$Z_3(R) = g_1^3 + 3g_1g_2 + 2g_3 \tag{16}$$

$$Z_4(R) = g_1^6 + 9g_1^2g_2^2 + 8g_3^2 + 6g_2g_4 \tag{17}$$

$$Z_5(R) = g_1^{10} + 10g_1^4g_2^3 + 15g_1^2g_2^4 + 20g_1g_3^3 + 30g_2g_4^2 + 24g_5^2 + 20g_1g_3g_6 \tag{18}$$

$$Z_6(R) = g_1^{15} + 15g_1^7g_2^4 + 60g_1^3g_2^6 + 40g_1^3g_3^4 + 40g_3^5 + 180g_1g_2g_4^3 + 144g_5^3 + 120g_1g_2g_3^2g_6 + 120g_3g_6^2 \tag{19}$$

$$Z_7(R) = g_1^{21} + 21g_1^{11}g_2^5 + 105g_1^5g_2^8 + 105g_1^3g_2^9 + 70g_1^6g_3^5 + 280g_3^7 + 210g_1^3g_2g_4^4 + 630g_1g_2^2g_4^4 + 504g_1g_5^4 + 420g_1^2g_2^2g_3^3g_6 + 210\, g_1^2g_2^2g_3g_6^2 + 840\, g_3g_6^3 + 720\, g_7^3 + 504\, g_1g_5^2g_{10} + 420\, g_2g_3g_4g_{12}. \tag{20}$$

Letting $g_i = 1 + x^i$ then gives a POLYNOMIAL $S_i(x)$, which is a GENERATING FUNCTION for (i.e., the terms of x^i give) the number of graphs with i EDGES. The total number of graphs having i edges is $S_i(1)$. The first few $S_i(x)$ are

$$S_2 = 1 + x \tag{21}$$

$$S_3 = 1 + x + x^2 + x^3 \tag{22}$$

$$S_4 = 1 + x + 2x^2 + 3x^3 + 2x^4 + x^5 + x^6 \tag{23}$$

$$S_5 = 1 + x + 2x^2 + 4x^3 + 6x^4 + 6x^5 + 6x^6 + 4x^7 + 2x^8 + x^9 + x^{10} \tag{24}$$

$$S_6 = 1 + x + 2x^2 + 5x^3 + 9x^4 + 15x^5 + 21x^6 + 24x^7 + 24x^8 + 21x^9 + 15x^{10} + 9x^{11} + 5x^{12} + 2x^{13} + x^{14} + x^{15} \tag{25}$$

$$S_7 = 1 + x + 2x^2 + 5x^3 + 10x^4 + 21x^5 + 21x^6 + 24x^7 + 41x^6 + 65x^7 + 97x^8 + 131x^9 + 148x^{10} + 148x^{11} + 131x^{12} + 97x^{13} + 65x^{14} + 41x^{15} + 21x^{16} + 10x^{17} + 5x^{18} + 2x^{19} + x^{20} + x^{21}, \quad (26)$$

giving the number of graphs with n nodes as 1, 2, 4, 11, 34, 156, 1044, ... (Sloane's A000088). King and Palmer (cited in Read 1981) have calculated S_n up to $n = 24$, for which

$$S_{24} = 195,704,906,302,078,447,922,174,862,416,\cdots \cdots 726,256,004,122,075,267,063,365,754,368. \quad (27)$$

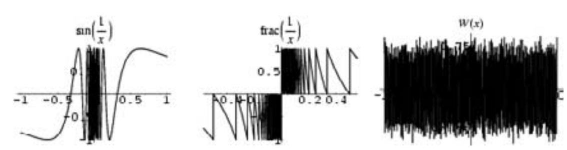
Graph (Function)

Given a function $f(x_1, \ldots, x_n)$ defined on a domain U, the graph of f is defined as the set of points (which often form a curve or surface) showing the values taken by f over U (or some portion of U). Technically, for real functions,



$$\text{graph } f(x) \equiv \{(x, f(x)) \in \mathbb{R}^2 : x \in U\}$$

$$\text{graph } f(x_1, \ldots, x_n) \equiv$$

$$\{(x_1, \ldots, x_n, f(x_1, \ldots, x_n)) \in \mathbb{R}^{n+1} : (x_1, \ldots, x_n) \in U\}.$$

A graph is sometimes also called a plot. Commenting on the unfortunate choice of the word "graph" in the completely different context of so-called graph theory, Gardner (1984, p. 91) notes, "The confusion of this term with the 'graphs' of analytic geometry is regrettable, but the term has stuck."

2-D and 3-D graphs can be produced in *Mathematica* using the commands Plot[f, {x, $xmin$, $xmin$}] and Plot3D[f, {x, $xmin$, $xmin$}, {y, $ymin$, $ymax$}], respectively.

Several examples of continuous functions which are notoriously difficult to graph are shown above: $\sin(1/x)$, the fractional part $\text{frac}(1/x)$, and the Weierstrass function. Good routines for plotting graphs use adaptive algorithms which plot more points in regions where the function varies most rapidly (Wagon 1991, Math Works 1992, Heck 1993, Wickham-Jones 1994). Tupper (1996) has developed an algorithm that rigorously proves the pixels it generates are "on" if and only if there exists a mathematical point within the region of space represented by that pixel that is a solution to the relation being graphed. Although this method attempts to produce graphs that satisfy strict mathematical

relationships, the problem of graphing is ultimately intractable, so no fixed algorithm can produce correct graphs for arbitrary relations.

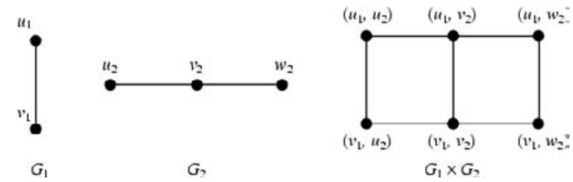
Graph Automorphism

An automorphism of a GRAPH is a GRAPH ISOMORPHISM with itself. The sets of automorphisms define a PERMUTATION GROUP. For every GROUP Γ, there exists a GRAPH whose automorphism group is isomorphic to Γ (Frucht 1939; Skiena 1990, p. 185). The automorphism groups of a graph characterize its symmetries, and are therefore very useful in determining certain of its properties.



The automorphism group of a GRAPH COMPLEMENT is the same as that for the original graph.

Graph Cartesian Product

The Cartesian graph product $G = G_1 \square G_2$ of graphs G_1 and G_2 with disjoint point sets V_1 and V_2 and edge sets X_1 and X_2 is the graph with point set $V_1 \times V_2$ and $u = (u_1, u_2)$ adjacent with $v = (v_1, v_2)$ whenever [$u_1 = v_1$ and u_2 adj v_2] or [$u_2 = v_2$ and u_1 adj v_1] (Harary 1994, p. 22).

Graph Cartesian products can be computed using `GraphProduct[G1, G2]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Graph Categorical Product

This entry contributed by NICOLAS BRAY

The GRAPH PRODUCT denoted $G \times H$ and defined by the adjacency relations (g adj g' and h adj h').

See also GRAPH PRODUCT

Graph Center

The center of a GRAPH G is the set of vertices of GRAPH ECCENTRICITY equal to the GRAPH RADIUS (i.e., the set of CENTRAL POINTS). In the above illustration, center nodes are shown in red. The following table gives the number of n-node simple unlabeled graphs having k center nodes.

k	Sloane	n = 1, 2, ...
1	A052437	1, 0, 1, 2, 8, 29, 180, ...
2	A052438	0, 2, 0, 2, 4, 19, 84, ...
3	A052439	0, 0, 3, 0, 4, 18, 119, ...
4	A052340	0, 0, 0, 7, 0, 18, 118, ...
5	A052341	0, 0, 0, 0, 18, 0, 129, ...
6		0, 0, 0, 0, 0, 72, 0, ...
7		0, 0, 0, 0, 0, 0, 414, ...

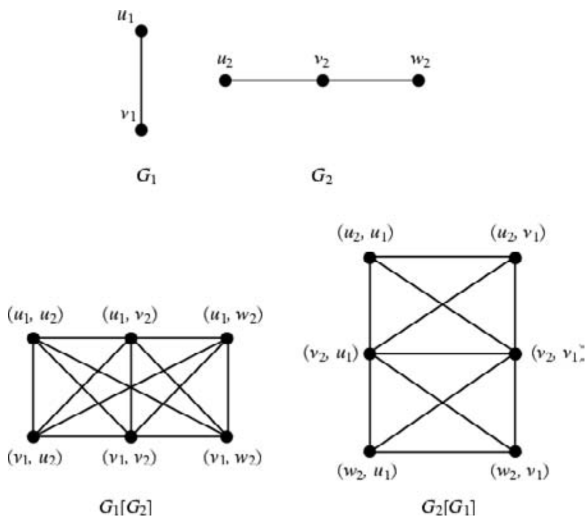
Graph Complement



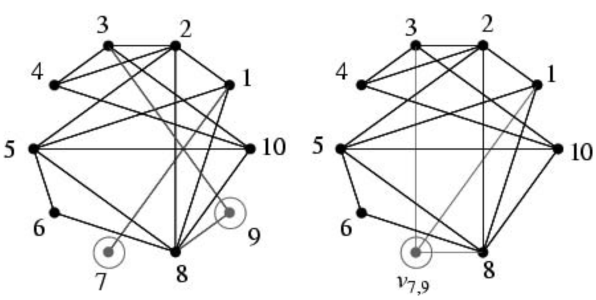
The complement of a graph G_n on n nodes is the graph G'_n (sometimes denoted $\bar{G}_n$) on the same nodes, but with the vertices in G_n omitted and the omitted vertices in G_n included. The GRAPH SUM $G_n + G'_n$ is therefore the COMPLETE GRAPH K_n. A graph complement can be given by the *Mathematica* command `GraphComplement[`*graph*`]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

See also COMPLETE GRAPH, GRAPH SUM, SELF-COMPLEMENTARY GRAPH

References

Skiena, S. "The Complement of a Graph." §3.2.3 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, p. 93, 1990.

Graph Composition



The composition $G = G_1[G_2]$ of graphs G_1 and G_2 with disjoint point sets V_1 and V_2 and edge sets X_1 and X_2 is the graph with point set $V_1 \times V_2$ and $u = (u_1, u_2)$ adjacent with $v = (v_1, v_2)$ whenever $[u_1 \text{ adj } v_1]$ or $[u_1 = v_1 \text{ and } u_2 \text{ adj } v_2]$ (Harary 1994, p. 22).

See also GRAPH PRODUCT

References

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, p. 22, 1994.

Graph Contraction

The contraction of an edge $\{v_i, v_j\}$ of a GRAPH is the graph obtained by replacing the two nodes v_1 and v_2 with a single node v such that v is adjacent to the union of the nodes to which v_1 and v_2 were originally adjacent. The figure above shows a random graph contracted on vertices v_7 and v_9. Graph contraction can be implemented using `Contract[g, {v1, v2}]` in the *Mathematica* add-on package `DiscreteMath‘Combinatorica‘` (which can be loaded with the command `<<DiscreteMath‘`).

References

Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, p. 91, 1990.

Graph Cycle

A cycle of a GRAPH is a subset of the EDGE-set of the GRAPH which forms a CHAIN, the first node of which is also the last. This type of cycle is also called a CIRCUIT. Cycle graphs can be constructed using `Cycle[n]` in the *Mathematica* add-on package `DiscreteMath‘Combinatorica‘` (which can be loaded with the command `<<DiscreteMath‘`).

The minimum number of swaps between vertices in a random circular embedding of a cycle to put in its standard configuration is considered by Björner and Wachs (1982) and (Stanley 1986).

Graph Diameter

The length $\max_{u, v} d(u, v)$ of the "longest shortest path" (i.e., the longest GRAPH GEODESIC) between any two VERTICES (u, v) of a GRAPH. In other words, a graph's diameter is the largest number of vertices which must be traversed in order to travel from one vertex to another when paths which backtrack, detour, or loop are excluded from consideration. The above RANDOM GRAPHS on 10 vertices have diameters 3, 4, 5, and 7, respectively.

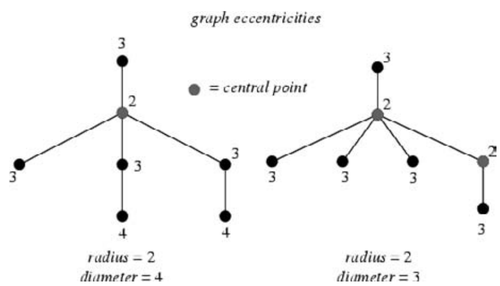
Graph Difference

The graph difference of graphs G and H is the graph with ADJACENCY MATRIX given by the difference of adjacency matrices of G and H. A graph difference is defined when the orders of G and H are the same, and can be computed using `GraphDifference[g, h]`



in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

See also GRAPH SUM

References

Skiena, S. "Sum and Difference." §4.1.2 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, p. 131, 1990.

Graph Eccentricity

The eccentricity of a node v in a CONNECTED GRAPH G is length $\max_u d(u, v)$ of the longest of all the shortest paths between v and every other point in G. The maximum eccentricity is the GRAPH DIAMETER. The minimum graph eccentricity is called the GRAPH RADIUS.

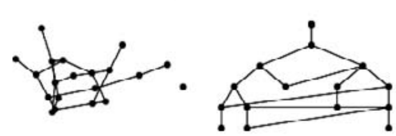
Graph Embedding



A particular drawing of a GRAPH (with sometimes added constraint that the embedding be *planar*, i.e., has no crossing edges). The above figure shows the first several circular embeddings of the CUBICAL GRAPH.

While the underlying object is independent of the embedding, a clever choice of embedding can lead to particularly illuminating diagrams. For example, the circular embedding of the CUBICAL GRAPH depicted above illustrates this graph's inherent symmetries.

circular embedding radial embedding ranked embedding

spring embedding rooted embedding

Skiena (1990) considers a number of different types of embeddings, including circular, ranked, radial, rooted, and spring.

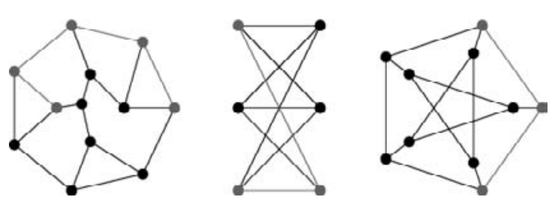
Graph Genus



The genus of a graph is the minimum number of handles that must be added to the plane to embed the graph without any crossings.

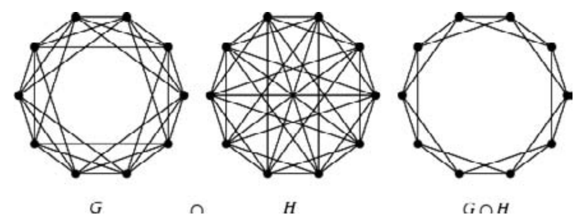
See also CROSSING NUMBER (GRAPH), PLANAR GRAPH

References

Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, 1990.

Graph Geodesic

A shortest path between two VERTICES (u, v) of a GRAPH (Skiena 1990, p. 225). There may be more than one different shortest paths, all of the same length. Graph geodesics may be found using a BREADTH-FIRST TRAVERSAL (Moore 1959) or using DIJKSTRA'S ALGORITHM (Skiena 1990, p. 225). A graph geodesic can be found using ShortestPath[g, s, e] in the *Mathematica* add-on package DiscreteMath\`Combinatorica\` (which can be loaded with the command << DiscreteMath\`).



The length of the maximum graph geodesic in a given graph is called the GRAPH DIAMETER.

Skiena, S. "Shortest Paths." §6.1 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, pp. 225–53, 1990.

Graph Intersection

Let S be a set and $F = \{S_1, \ldots, S_p\}$ a nonempty family of distinct nonempty subsets of S whose union is $\cup_{i=1}^{p} S_i = S$. The intersection graph of F is denoted $\Omega(F)$ and defined by $V(\Omega(F)) = F$, with S_i and S_j adjacent whenever $i \neq j$ and $S_i \cap Sj \neq \emptyset$. Then a GRAPH G is an intersection graph on S if there exists a family F of subsets for which G and $\Omega(F)$ are ISOMORPHIC GRAPHS (Harary 1994, p. 19). Graph intersections can be computed using GraphIntersection[g, h] in the *Mathematica* add-on package DiscreteMath\`Combinatorica\` (which can be loaded with the command << DiscreteMath\`).

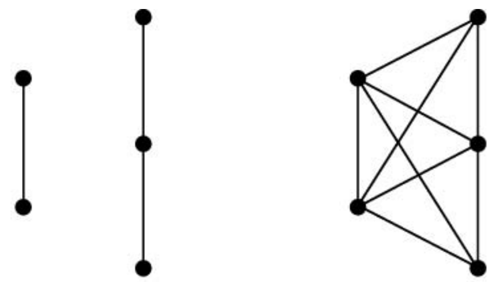
See also GRAPH UNION, INTERSECTION NUMBER

References

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, 1994.
Skiena, S. "Unions and Intersections." §4.1.1 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, pp. 129–31, 1990.

Graph Isomorphism

An isomorphism between two graphs is a one-to-one mapping between their two sets of vertices.



See also GRAPH AUTOMORPHISM, ISOMORPHIC GRAPHS

References

Graph Join

G_1 G_2 G_1+G_2

The join $G=G_1+G_2$ of graphs G_1 and G_2 with disjoint point sets V_1 and V_2 and edge sets X_1 and X_2 is the GRAPH UNION $G_1 \cup G_2$ together with all the edges joining V_1 and V_2 (Harary 1994, p. 21). Graph joins can be computed using `GraphJoin[G1, G2]` in the *Mathematica* add-on package `DiscreteMath`-Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

A complete k-partite graph $k_{i, j, \ldots}$ is the graph join of empty graphs on i, j, ... nodes. A WHEEL GRAPH is the join of a CYCLE GRAPH and the singleton graph. Finally, a STAR GRAPH is the join of an EMPTY GRAPH and the singleton graph (Skiena 1990, p. 132).

See also GRAPH SUM, GRAPH UNION

Graph Lexographic Product

This entry contributed by NICOLAS BRAY

The GRAPH PRODUCT denoted $G^{\bullet}H$ and defined by the adjacency relations (g adj g') or ($g=g'$ and h adj h').

See also GRAPH PRODUCT

Graph Power

The kth power of a GRAPH G is a graph with the same set of vertices as G and an edge between two vertices IFF there is a path of length at most k between them (Skiena 1990, p. 229). Since a path of length two between vertices u and v exists for every vertex w such that $\{u, w\}$ and $\{w, v\}$ are edges in G, the square of the ADJACENCY MATRIX of G counts the number of such paths. Similarly, the (u, v)th element of the kth power of the ADJACENCY MATRIX of G gives the number of paths of length k between vertices u and v. The graph kth power is then defined as the graph whose adjacency matrix given by the sum of the first k powers of the ADJACENCY MATRIX,

$$\operatorname{adj}(G^k)=\sum_{i=1}^{k}[\operatorname{adj}(G)]^i,$$

which counts all paths of length up to k (Skiena 1990, p. 230).

Raising any graph to the power of its GRAPH DIAMETER gives a COMPLETE GRAPH. The square of any BICONNECTED GRAPH is HAMILTONIAN (Fleischner 1974, Skiena 1990, p. 231). Mukhopadhyay (1967) has considered "square root graphs," whose square gives a given graph G (Skiena 1990, p. 253).

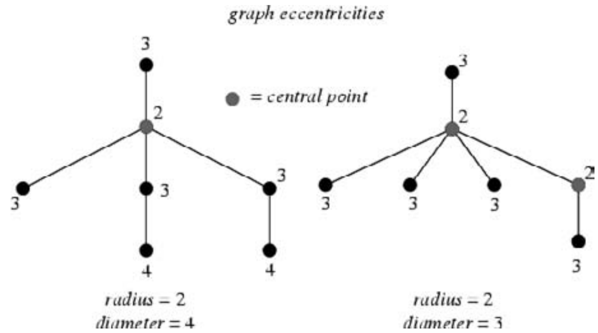
Graph Product

This entry contributed by NICOLAS BRAY

In general, a graph product of two graphs G and H is a new graph whose VERTEX SET is $V(G) \times V(H)$ and where, for any two vertices (g, h) and (g', h') in the product, the adjacency of those two vertices is determined entirely by the adjacency (or equality, or non-adjacency) of g and g', and that of h and h'. There are $3 \times 3 - 1 = 8$ cases to be decided (three possibilities for each, with the case where both are equal eliminated) and thus there are $2^8 = 256$ different types of graph products that can be defined.

The most commonly used graph products, given by conditions sufficient and necessary for adjacency, are summarized in the following table (Hartnell and Rall 1998). Note that the terminology is not quite standardized, so these products may actually be referred to by different names by different sources. Many other graph products can be found in Jensen and Toft (1994).

graph product name	symbol	definition
GRAPH CARTESIAN PRODUCT	$G \square H$	$(g = g'$ and h adj $h')$ or $(g$ adj g' and $h = h')$
GRAPH CATEGORICAL PRODUCT	$G \times H$	$(g$ adj g' and h adj $h')$
GRAPH LEXOGRAPHIC PRODUCT	$G \cdot H$	$(g$ adj $g')$ or $(g = g'$ and h adj $h')$
GRAPH STRONG PRODUCT	$G \boxtimes H$	$(g = g'$ and h adj $h')$ or $(g$ adj g' and $h = h')$ or $(g$ adj g' and h adj $h')$



See also GRAPH CARTESIAN PRODUCT

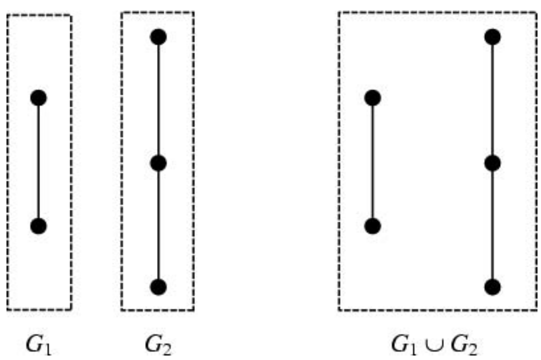
Graph Thickness

The thickness of a GRAPH G is the minimum number of PLANAR SUBGRAPHS of g whose GRAPH UNION is g (skiena 1990, p. 251).

References



Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, 1990.

Graph Two-Coloring

Assignment of each EDGE of a GRAPH to one of two color classes ("red" or "green").

See also BLUE-EMPTY GRAPH, MONOCHROMATIC FORCED TRIANGLE

Graph Union

The union $G = G_1 \cup G_2$ of graphs G_1 and G_2 with disjoint point sets V_1 and V_2 and edge sets X_1 and X_2 is the graph with $V = V_1 \cup V_2$ and $X = X_1 \cup X_2$ (Harary 1994, p. 21). Graph unions can be computed using `GraphUnion[g, h]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

Graphic Sequence

A graphic sequence is a sequence of numbers which can be the DEGREE SEQUENCE of some GRAPH. A sequence can be checked to determine if it is graphic using `GraphicQ[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

Erdos and Gallai (1960) proved that a DEGREE SEQUENCE $\{d_1, \ldots, d_n\}$ is graphic IFF the sequence obeys the property

$$\sum_{i=1}^{r} d_i \leq r(r-1) + \sum_{i=r+1}^{n} \min(r, d_i)$$

for each integer $r < n$ (Skiena 1990, p. 157), and this condition also generalizes to DIRECTED GRAPHS. In addition, Hakimi (1962) and Havel (1955) showed that if a DEGREE SEQUENCE is graphic, then there exists a GRAPH G such that the node of highest degree is adjacent to the $\Delta(G)$ next highest degree vertices of G, where $\Delta(G)$ is the maximum degree of G.

No degree sequence can be graphic if all the degrees occur with multiplicity 1 (Behzad and Chartrand 1967, p. 158; Skiena 1990, p. 158). Any degree sequence whose sum is EVEN can be realized by a MULTIGRAPH having loops (Hakimi 1962; Skiena 1990, p. 158).

Graphical Partition

A partition $\{a_1, \ldots, a_n\}$ is called graphical if there exists a GRAPH G having DEGREE SEQUENCE $\{a_1, \ldots, a_n\}$. The number of graphical partitions on n-node graphs is therefore the same as the number of n-node graphs with no ISOLATED POINTS. A graphical partition of order p is one for which the sum of degrees is p. A p-graphical partition only exists for

EVEN p.

{2, 2, 2, 1, 1} {2, 2, 2, 1, 1}

It is possible for two topologically distinct graphs to have the same DEGREE SEQUENCE.

For $n = 2, 4, 6, ...$, the numbers of graphical partitions $p_g(n)$ are 1, 2, 5, 9, 17, ... (Sloane's A000569).

Erdos and Richmond (1989) showed that

$$\liminf_{n\to\infty} \sqrt{2n}p_g(2n) \geq \frac{\pi}{\sqrt{6}}$$

and

$$\limsup_n p_g(2n) \leq 0.4258.$$

Graphical Representation

FERRERS DIAGRAM

Graphoid

A graphoid consists of a set M of elements together with two collections $\mathfrak{C}$ and $\mathfrak{D}$ of nonempty subsets of M, called circuits and cocircuits respectively, such that

1. For any $C \in \mathfrak{C}$ and $D \in \mathfrak{D}$, $|C \cap D| \neq 1$,
2. No circuit properly contains another circuit and no cocircuit properly contains another cocircuit,
3. For any painting of M with colors exactly one element green and the rest either red or blue, there exists either (a) a circuit C containing the green element and no red elements, or (b) a cocircuit D containing the green element and no blue elements.

Grassmann Algebra

EXTERIOR ALGEBRA

Grassmann Coordinates

An $(m+1)$-D SUBSPACE W of an $(n+1)$-D VECTOR SPACE V can be specified by an $(m+1)\times(n+1)$ MATRIX whose rows are the coordinates of a BASIS of W. The set of all $\binom{n+1}{m+1}$ $(m+1)\times(m+1)$ MINORS of this MATRIX are then called the Grassmann (or sometimes Plücker; Stofli 1991) coordinates of w, where $\binom{a}{b}$ is a BINOMIAL COEFFICIENT. Hodge and Pedoe (1952) give a thorough treatment of Grassmann coordinates.

Grassmann Manifold

A special case of a FLAG MANIFOLD. A Grassmann manifold is a certain collection of vector SUBSPACES of a VECTOR SPACE. In particular, $g_{n,\,k}$ is the Grassmann manifold of k-dimensional subspaces of the VECTOR SPACE $\mathbb{R}^n$. It has a natural MANIFOLD structure as an orbit-space of the STIEFEL MANIFOLD $v_{n,k}$ of orthonormal k-frames in $\mathbb{G}^n$. One of the main things about Grassmann manifolds is that they are classifying spaces for VECTOR BUNDLES.

Gray Code

An encoding of numbers so that adjacent numbers have a single DIGIT differing by 1. A BINARY Gray code with n DIGITS corresponds to a HAMILTONIAN PATH on an n-D HYPERCUBE (including direction reversals). The term Gray code is often used to refer to a "reflected" code, or more specifically still, the binary reflected Gray code.

To convert a BINARY number $d_1 d_2 \cdots d_{n-1} d_n$ to its corresponding binary reflected Gray code, start at the right with the digit d_n (the nth, or last, DIGIT). If the d_{n-1} is 1, replace d_n by $1-d_n$; otherwise, leave it unchanged. Then proceed to d_{n-1}. Continue up to the first DIGIT d_1, which is kept the same since d_0 is assumed to be a 0. The resulting number $g_1 g_2 \cdots g_{n-1} g_n$ is the reflected binary Gray code.

To convert a binary reflected Gray code $g_1 g_2 \cdots g_{n-1} g_n$ to a BINARY number, start again with the nth digit, and compute

$$\sum_n \equiv \sum_{i=1}^{n-1} g_i \pmod{2}.$$

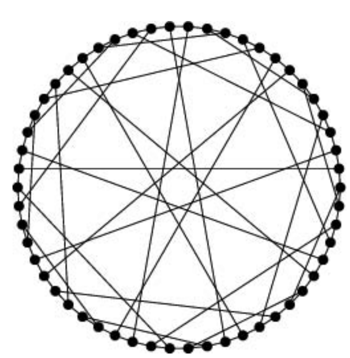
If Σ_n is 1, replace g_n by $1-g_n$; otherwise, leave it the unchanged. Next compute

$$\sum_{n-1} \equiv \sum_{i=1}^{n-2} g_i \pmod{2},$$

and so on. The resulting number $d_1 d_2 \cdots d_{n-1} d_n$ is the BINARY number corresponding to the initial binary reflected Gray code.

The code is called reflected because it can be generated in the following manner. Take the Gray code 0, 1. Write it forwards, then backwards: 0, 1, 1, 0. Then append 0s to the first half and 1s to the second half: 00, 01, 11, 10. Continuing, write 00, 01, 11, 10, 10, 11, 01, 00 to obtain: 000, 001, 011, 010, 110, 111, 101, 100, ... (Sloane's A014550). Each iteration therefore doubles the number of codes. The Gray codes corresponding to the first few nonnegative integers are given in the following table.

0	0	20	11110	40	111100
1	1	21	11111	41	111101
2	11	22	11101	42	111111
3	10	23	11100	43	111110
4	110	24	10100	44	111010
5	111	25	10101	45	111011
6	101	26	10111	46	111001
7	100	27	10110	47	111000
8	1100	28	10010	48	101000
9	1101	29	10011	49	101001
10	1111	30	10001	50	101011
11	1110	31	10000	51	101010
12	1010	32	110000	52	101110
13	1011	33	110001	53	101111
14	1001	34	110011	54	101101
15	1000	35	110010	55	101100
16	11000	36	110110	56	100100
17	11001	37	110111	57	100101
18	11011	38	110101	58	100111
19	11010	39	110100	59	100110



The binary reflected Gray code is closely related to the solutions of the TOWERS OF HANOI and BAGUENAUDIER, as well as to Hamiltonian circuits of hypercube graphs (Skiena 1990, p. 149).

Gray Graph

A CUBIC GRAPH on 54 vertices that is EDGE- but not

VERTEX-TRANSITIVE; the smallest known such example. It was discovered by Marion C. Gray in 1932, and was first published by Bouwer (1968). It has GIRTH 8, GRAPH DIAMETER 6, has |Aut G|=1296, and is the Levi graph of two dual, triangle-free, point-, line-, and flag-transitive, non-self-dual 27_3 configurations (Maruvic and Pisanski 2000). The symmetric embedding illustrated above is due to (Maruvic and Pisanski 2000). It can be constructed by taking three copies of the COMPLETE BIPARTITE GRAPH $K_{3,3}$ and, for a particular edge e, subdividing e in each of the three copies, joining the resulting three vertices to a new vertex, and repeating with each edge.

Grazing Goat Problem

GOAT PROBLEM

Great Circle

A great circle is a SECTION of a SPHERE which contains a DIAMETER of the SPHERE (Kern and Bland 1948, p. 87). Sections of the sphere that do not contain a diameter are called SMALL CIRCLES.

The shortest path between two points on a SPHERE, also known as an ORTHODROME, is a segment of a great circle. To find the great circle (GEODESIC) distance between two points located at LATITUDE δ and LONGITUDE λ of (δ_1, λ_1) and (δ_2, λ_2) on a SPHERE of RADIUS a, convert SPHERICAL COORDINATES to CARTESIAN COORDINATES using

$$\mathbf{r}_i = a\begin{bmatrix}\cos\lambda_i\cos\delta_i\\ \sin\lambda_i\cos\delta_i\\ \sin\delta_i\end{bmatrix}. \tag{1}$$

(Note that the LATITUDE δ is related to the COLATITUDE ϕ of SPHERICAL COORDINATES by $\delta = 90° - \phi$, so the conversion to CARTESIAN COORDINATES replaces $\sin\phi$ and $\cos\phi$ by $\cos\delta$ and $\sin\delta$, respectively.) Now find the ANGLE α between $\mathbf{r}_1$ and $\mathbf{r}_2$ using the DOT PRODUCT,

$$\begin{aligned}\cos\alpha &= \hat{\mathbf{r}}_1\cdot\hat{\mathbf{r}}_2\\ &= \cos\delta_1\cos\delta_2(\sin\lambda_1\sin\lambda_2+\cos\lambda_1\cos\lambda_2)\\ &\quad+\sin\delta_1\sin\delta_2\\ &= \cos\delta_1\cos\delta_2\cos(\lambda_1-\lambda_2)+\sin\delta_1\sin\delta_2.\end{aligned} \tag{2}$$

The great circle distance is then

$$\begin{aligned}d = a\cos^{-1}[&\cos\delta_1\cos\delta_2\cos(\lambda_1-\lambda_2)\\ &+\sin\delta_1\sin\delta_2].\end{aligned} \tag{3}$$

For the Earth, the *equatorial* RADIUS is $a \approx 6378$ km, or 3963 (statute) miles. Unfortunately, the FLATTENING of the Earth cannot be taken into account in this simple derivation, since the problem is considerably more complicated for a SPHEROID or ELLIPSOID (each of which has a RADIUS which is a function of LATITUDE). This leads to extremely complicated expressions for OBLATE SPHEROID GEODESICS and GEODESICS on other ELLIPSOIDS.

A great circle becomes a straight line in a GNOMONIC PROJECTION (Steinhaus 1983, pp. 220–21).

The equation of the great circle can be explicitly computed using the GEODESIC formalism. Writing

$$u = \lambda \tag{4}$$

$$v = \delta = \tfrac{1}{2}\pi - \phi \tag{5}$$

gives the P, Q, and R parameters of the GEODESIC (which are just combinations of the PARTIAL DERIVATIVES) as

$$P \equiv \left(\frac{\partial x}{\partial u}\right)^2+\left(\frac{\partial y}{\partial u}\right)^2+\left(\frac{\partial z}{\partial u}\right)^2 = a^2\sin^2 v \tag{6}$$

$$Q \equiv \frac{\partial x}{\partial u}\frac{\partial x}{\partial v}+\frac{\partial y}{\partial u}\frac{\partial y}{\partial v}+\frac{\partial z}{\partial u}\frac{\partial z}{\partial v} = 0 \tag{7}$$

$$R \equiv \left(\frac{\partial x}{\partial v}\right)^2+\left(\frac{\partial y}{\partial v}\right)^2+\left(\frac{\partial z}{\partial v}\right)^2 = a^2. \tag{8}$$

The GEODESIC differential equation then becomes

$$\cos v \sin^4 v + 2 \cos v \sin^2 v v'^2 + \cos v v'^4 - \sin v v'' = 0. \tag{9}$$

However, because this is a special case of $Q = 0$ with P and R explicit functions of v only, the GEODESIC solution takes on the special form

$$v = c_1 \int \sqrt{\frac{R}{P^2 - c_1^2 P}}\, dv = c_1 \int \frac{dv}{a^2 \sin^4 v - c_1^2 \sin^2 v}$$
$$= \int \frac{dv}{\sin v \sqrt{\left(\frac{a}{c_1}\right)^2 \sin^2 v - 1}}$$
$$= -\tan^{-1}\left[\frac{\cos v}{\sqrt{\left(\frac{a}{c_1}\right)^2 - 1}}\right] + c_2 \tag{10}$$

(Gradshteyn and Ryzhik 2000, p. 174, eqn. 2.599.6), which can be rewritten as

$$v = -\sin^{-1}\left(\frac{\cot v}{\sqrt{\left(\frac{a}{c_1}\right)^2 - 1}}\right) + c_2. \tag{11}$$

It therefore follows that

$$(\sin c_2) a \sin v \cos u - (\cos c_2) a \sin v \sin u - \frac{a \cos v}{\sqrt{\left(\frac{a}{c_1}\right)^2 - 1}} = 0. \tag{12}$$

This equation can be written in terms of the CARTESIAN COORDINATES as

$$x \sin c_2 - y \cos c_2 - \frac{z}{\sqrt{\left(\frac{a}{c_1}\right)^2 - 1}} = 0, \tag{13}$$

which is simply a PLANE passing through the center of the SPHERE and the two points on the surface of the SPHERE.

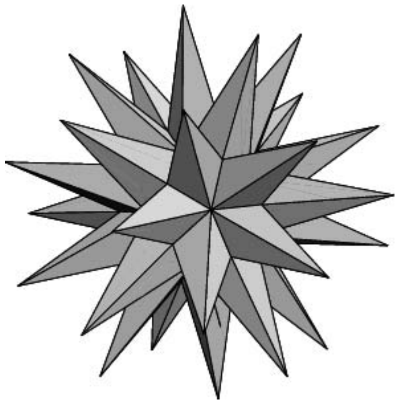
Great Cubicuboctahedron

The UNIFORM POLYHEDRON U_{14} whose DUAL POLYHEDRON is the GREAT HEXACRONIC ICOSITETRAHEDRON. It has WYTHOFF SYMBOL $3\,4|\frac{4}{3}$ and is Wenninger model W_{77}. Its faces are $8\{3\}+6\{4\}+6\{\frac{8}{3}\}$. It is a FACETED version of the CUBE. The CIRCUMRADIUS of a great cubicuboctahedron with unit edge length is

$$r = \tfrac{1}{2}\sqrt{5 - 2\sqrt{2}}.$$



The CONVEX HULL of the great cubicuboctahedron is the Archimedean TRUNCATED CUBE A_9, whose dual is the SMALL TRIAKIS OCTAHEDRON, so the dual of the great cubicuboctahedron (i.e., the GREAT HEXACRONIC ICOSITETRAHEDRON) is one of the stellations of the SMALL TRIAKIS OCTAHEDRON (Wenninger 1983, p. 57).

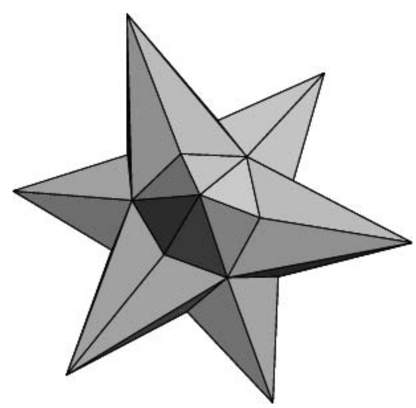
Great Dirhombicosidodecahedron

The UNIFORM POLYHEDRON U_{75} whose DUAL is the GREAT DIRHOMBICOSIDODECACRON. This POLYHEDRON is exceptional because it cannot be derived from SCHWARZ TRIANGLES and because it is the only UNIFORM POLYHEDRON with more than six POLYGONS surrounding each VERTEX (four SQUARES alternating with two TRIANGLES and two PENTAGRAMS). This unique polyhedron has features in common with both snub forms and hemipolyhedra, and its octagrammic faces pass through the origin.

It has pseudo-WYTHOFF SYMBOL $|\frac{3}{2}\,\frac{5}{3}\,3\,\frac{5}{2}$. Its faces are $40\{3\}+60\{4\}+24\{\frac{5}{2}\}$, and its CIRCUMRADIUS for unit edge length is



$$R=\tfrac{1}{2}\sqrt{2}.$$

Great Dodecadodecahedron

DODECADODECAHEDRON

Great Dodecahedron

The KEPLER-POINSOT SOLID which is the DUAL of the SMALL STELLATED DODECAHEDRON. It is also UNIFORM POLYHEDRON U_{35} and Wenninger model W_{20}. Its SCHLÄFLI SYMBOL is $\{5, \frac{5}{2}\}$, and its WYTHOFF SYMBOL is $\frac{5}{2}|25$. Its faces are $12\{5\}$. Its CIRCUMRADIUS for unit edge length is

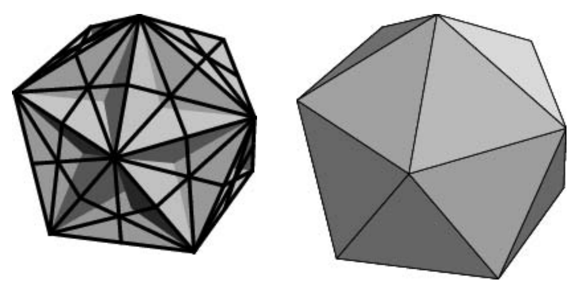
$$R=\tfrac{1}{2}\,5^{1/4}\phi^{1/2}a=\tfrac{1}{4}\,5^{1/4}\sqrt{2(1+\sqrt{5})},$$

where ϕ is the GOLDEN RATIO. It can be constructed by CUMULATION of a unit edge-length ICOSAHEDRON by a pyramid with height $-\sqrt{\tfrac{1}{6}(7-3\sqrt{5}}$.. This gives side of lengths

$$s_1=\tfrac{1}{2}(\sqrt{5}-1)=\phi-1 \tag{1}$$

$$s_2=1 \tag{2}$$

The result solid has SURFACE AREA and VOLUME



$$S=15\sqrt{5-2\sqrt{5}} \tag{3}$$

$$V=\tfrac{5}{4}(\sqrt{5}-1). \tag{4}$$

Schläfli (1901, p. 134) did not recognize the great dodecahedron because it, like the SMALL STELLATED DODECAHEDRON, satisfies

$$N_0-N_1+N_2=12-30+12=-6, \tag{5}$$

where N_0 is the number of vertices, N_1 the number of edges, and N_2 the number of faces (Coxeter 1973, p. 172), thus violating the POLYHEDRAL FORMULA.

The CONVEX HULL of the great dodecahedron is a regular ICOSAHEDRON and the dual of the ICOSAHEDRON is the DODECAHEDRON, so the dual of the great dodecahedron (the SMALL STELLATED DODECAHEDRON) is one of the DODECAHEDRON STELLATIONS (Wenninger 1983, pp. 35 and 40)

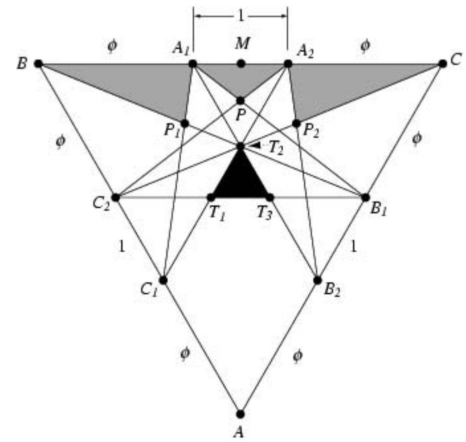
Wenninger, M. J. *Dual Models.* Cambridge, England: Cambridge University Press, p. 65, 1983.

Great Icosahedron

One of the KEPLER-POINSOT SOLIDS whose DUAL is the GREAT STELLATED DODECAHEDRON. It is also UNIFORM POLYHEDRON U_{53}, Wenninger model W_{22}, and has SCHLÄFLI SYMBOL $\{3, \frac{5}{2}\}$ and WYTHOFF SYMBOL $3\frac{5}{2}|\frac{5}{3}$. Its faces are $20\{3\}+12\{\frac{5}{2}\}+12\{\frac{10}{3}\}$.

The great icosahedron can most easily be constructed by building a "squashed" dodecahedron (top right figure) from the corresponding net (top left). Then, using the net shown in the bottom left figure, build 12 PENTAGRAMMIC PYRAMIDS (bottom middle figure) and affix them into the dimples (bottom right). This method of construction is given in Cundy and Rollett (1989, pp. 98–9). If the edge lengths of the dodecahedron are unity, then the height of the pentagrammic pyramid (above the dodecahedron faces) is given by solving the equation for the SLANT HEIGHT of a PENTAGONAL PYRAMID

$$s=\sqrt{h^2+\tfrac{1}{10}(5+\sqrt{5})a^2} \tag{1}$$



with $a=1$, giving

$$h=\sqrt{\tfrac{1}{5}(5+2\sqrt{5})}. \tag{2}$$

The distance from the center of the dodecahedron to the apex of a pyramid is then given by

$$H=h+r=\tfrac{1}{2}\sqrt{\tfrac{1}{2}(25+11\sqrt{5})}, \tag{3}$$

where r is the INRADIUS of the DODECAHEDRON.

The dimensions of the pentagrammic pyramid can be by examining a triangular section of the great icosahedron. In this triangle, each side is divided in the ratios $\phi:1:\phi$, and lines are drawn as shown. Then the light shaded portions on the left and right correspond to sides of two pyramids and the center shaded portion is the "lip" of the pyramid between the first two pyramids. Furthermore, the filled portion of the diagram corresponds to one face of the ICOSAHEDRON inscribed in the great icosahedron. In the notation of the figure above,

$$|MP|=\tfrac{1}{10}\sqrt{15} \tag{4}$$

$$|MT_2|=\tfrac{1}{2}\sqrt{3} \tag{5}$$

$$|T_1T_3|=\tfrac{1}{2}(\sqrt{5}-1)=\phi-1 \tag{6}$$

$$|CP_2|=\sqrt{\tfrac{1}{5}(7+3\sqrt{5})} \tag{7}$$

$$|PA_2|=\tfrac{1}{5}\sqrt{10}. \tag{8}$$

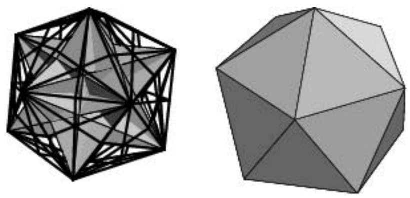
The great icosahedron constructed from the DODECAHEDRON with unit edge lengths has edge lengths (where edges are interpreted to be broken where facial plane intersect) given by

$$s_1=\tfrac{1}{5}\sqrt{10} \tag{9}$$

$$s_2=1 \tag{10}$$

$$s_3=\tfrac{1}{2}(1+\sqrt{5}) \tag{11}$$

$$s_4=\sqrt{\tfrac{1}{5}(7+3\sqrt{5})}. \tag{12}$$



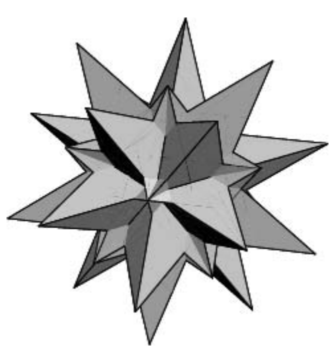
Its CIRCUMRADIUS is

$$R=\tfrac{1}{2}\sqrt{\tfrac{1}{2}(25+11\sqrt{5})}, \tag{13}$$

and the SURFACE AREA and VOLUME are then

$$S=3\sqrt{3}(5+4\sqrt{5}) \tag{14}$$

$$V = \tfrac{1}{4}(25 + 9\sqrt{5}). \qquad (15)$$



The CONVEX HULL of the great icosahedron is a regular ICOSAHEDRON and the dual of the ICOSAHEDRON is the DODECAHEDRON, so the dual of the great icosahedron is one of the DODECAHEDRON STELLATIONS (Wenninger 1983, p. 40)

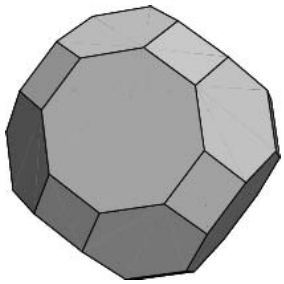
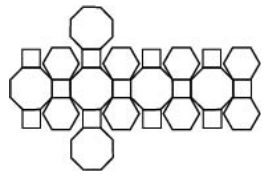
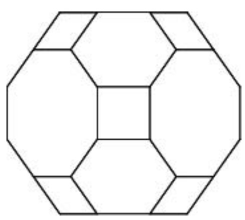
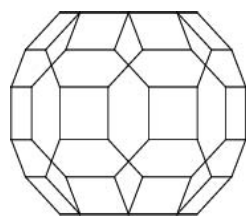
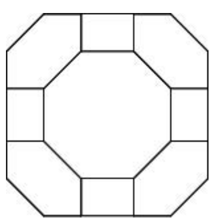
Great Rhombicosidodecahedron (Uniform)

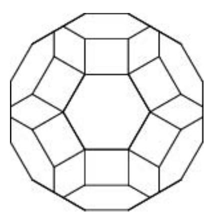












The UNIFORM POLYHEDRON U_{67}, also called the QUASIRHOMBICOSIDODECAHEDRON, whose DUAL is the GREAT DELTOIDAL HEXECONTAHEDRON. It has SCHLÄFLI SYMBOL r' $\left\{\begin{smallmatrix}3\\ \frac{5}{2}\end{smallmatrix}\right\}$. It has WYTHOFF SYMBOL 3 $\frac{5}{2}$|2. Its faces are $20\{3\}+30\{4\}+12\{\frac{5}{2}\}$. For unit edge length, its CIRCUMRADIUS is

$$R=\tfrac{1}{2}\sqrt{11-4\sqrt{5}}.$$

References

Wenninger, M. J. *Polyhedron Models.* Cambridge, England: Cambridge University Press, pp. 162–63, 1989.

Great Rhombicuboctahedron (Archimedean)

The 26-faced ARCHIMEDEAN SOLID A_3 consisting of faces $12\{4\}+8\{6\}+6\{8\}$. It is sometimes (improperly) called the truncated cuboctahedron, and is also called the rhombitruncated cuboctahedron. It is UNIFORM POLYHEDRON U_{11} and Wenninger model W_{15}. It has SCHLÄFLI SYMBOL t $\left\{ {3 \atop 4} \right\}$ and WYTHOFF SYMBOL $2\ 3\ 4|$.

The SMALL CUBICUBOCTAHEDRON is a FACETED version of the great rhombicuboctahedron.

Its DUAL is the DISDYAKIS DODECAHEDRON, also called the HEXAKIS OCTAHEDRON. The INRADIUS r of the dual, MIDRADIUS ρ of the solid and dual, and CIRCUMRADIUS R of the solid for $a=1$ are

$$r=\tfrac{3}{97}(14+\sqrt{2})\sqrt{13+6\sqrt{2}}\approx 2.20974$$

$$\rho=\tfrac{1}{2}\sqrt{12+6\sqrt{2}}\approx 2.26303$$

$$R=\tfrac{1}{2}\sqrt{13+6\sqrt{2}}\approx 2.31761.$$

Additional quantities are

$$t=\tan(\tfrac{1}{8}\pi)=\sqrt{2}-1$$

$$l=2t=2(\sqrt{2}-1)$$

$$h=1+l\,\sin(\tfrac{1}{4}\pi)=3-\sqrt{2}.$$

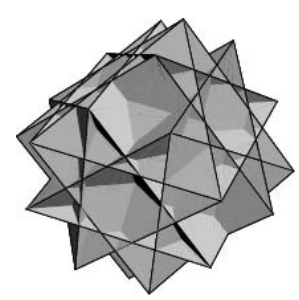
The distances between the solid center and centroids of the square and octagonal faces are

$$r_4=\tfrac{1}{2}(3+\sqrt{2}) \quad (1)$$

$$r_8=\tfrac{1}{2}(1+2\sqrt{2}). \quad (2)$$

The SURFACE AREA and VOLUME are

$$S=12(2+\sqrt{2}+\sqrt{3}) \quad (3)$$



$$V=22+14\sqrt{2}. \quad (4)$$

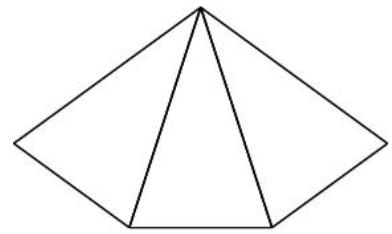
See also DUAL POLYHEDRON, GREAT TRUNCATED ICOSAHEDRON

References



Wenninger, M. J. *Dual Models.* Cambridge, England: Cambridge University Press, p. 75, 1983.

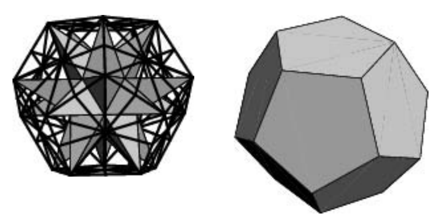
Great Stellated Dodecahedron

One of the KEPLER-POINSOT SOLIDS. It is also UNIFORM POLYHEDRON U_{52}, Wenninger model W_{41}, and is the third DODECAHEDRON STELLATION (Wenninger 1989). Its DUAL is the GREAT ICOSAHEDRON. The great stellated dodecahedron has SCHLÄFLI SYMBOL $\{\frac{5}{2},\ 3\}$ and WYTHOFF SYMBOL $3|2\ \frac{5}{2}$. Its faces are $12\{\frac{5}{2}\}$. Its CIRCUMRADIUS for unit edge length is

$$R = \tfrac{1}{2}\sqrt{3}\phi^{-1} = \tfrac{1}{4}\sqrt{3}(\sqrt{5}-1). \qquad (1)$$

The easiest way to construct a great stellated dodecahedron is by CUMULATION, i.e., to making 20 TRIANGULAR PYRAMIDS with side length $\phi = (1+\sqrt{5})/2$ (the GOLDEN RATIO) times the base and attaching them to the sides of an ICOSAHEDRON. The height of these pyramids is then $\sqrt{\frac{1}{6}(7+3\sqrt{5})}$.

Cumulating a DODECAHEDRON to construct a great stellated dodecahedron produces a solid with edge lengths



$$s_1 = 1 \qquad (2)$$

$$s_2 = \phi = \tfrac{1}{2}(1+\sqrt{5}). \qquad (3)$$

The SURFACE AREA and VOLUME of such a great stellated dodecahedron are

$$S = 15\sqrt{5+2\sqrt{5}} \qquad (4)$$

$$V = \tfrac{5}{4}(3+\sqrt{5}). \qquad (5)$$

The CONVEX HULL of the great stellated dodecahedron is a regular DODECAHEDRON and the dual of the DODECAHEDRON is the ICOSAHEDRON, so the dual of the great stellated dodecahedron (i.e., the GREAT ICOSAHEDRON) is one of the ICOSAHEDRON STELLATIONS (Wenninger 1983, p. 40)

Greater

A quantity a is said to be greater than b if a is larger than b, written $a > b$. If a is greater than or EQUAL to b, the relationship is written $a \geq b$. If a is MUCH GREATER than b, this is written $a \gg b$. Statements involving greater than and LESS than symbols are called INEQUALITIES.

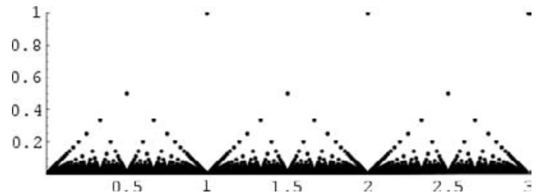
See also EQUAL, GREATER THAN/LESS THAN SYMBOL, INEQUALITY, LESS, MUCH GREATER

Greater Than/Less Than Symbol

When applied to a system possessing a length R at which solutions in a variable r change character (such as the gravitational field of a sphere as r runs from the interior to the exterior), the symbols

$$r_> \equiv \max(r, R)$$

$$r_< \equiv \min(r, R)$$



are sometimes used.

See also EQUAL, GREATER, LESS

Greatest Common Denominator

GREATEST COMMON DIVISOR

Greatest Common Divisor

The greatest common divisor GCD(a, b) of two positive integers a and b, sometimes written (a, b), is the largest DIVISOR common to a and b. For example, $\mathrm{GCD}(3, 5)=1$, $\mathrm{GCD}(12, 60)=12$, and $\mathrm{GCD}(12, 90)=6$. The greatest common divisor $\mathrm{GCD}(a, b, c, \ldots)$ can also be defined for three or more positive integers as the largest divisor shared by all of them. The plot above shows GCD(1, b) with rational $b=m/n$.

The greatest common divisor of a and b is implemented in *Mathematica* as GCD[a, b, ...].

If d is the greatest common divisor of a and b, then d is the largest possible integer satisfying

$$a=dx \tag{1}$$

$$b=dy \tag{2}$$

with x and y positive integers. Therefore, there exists an INTEGER RELATION between a and b OF THE FORM

$$ay-bx=0. \tag{3}$$

The EUCLIDEAN ALGORITHM can be used to find the greatest common divisor of two integers.

The notion can also be generalized to more general RINGS than simply the integers $\mathbb{Z}$. However, even for EUCLIDEAN RINGS, the notion of GCD of two elements of a ring is not the same as the GCD of two ideals of a ring. This is sometimes a source of confusion when studying rings other than $\mathbb{Z}$, such as polynomial rings in several variables.

To compute the GCD, write the PRIME FACTORIZATIONS of a and b,

$$a\equiv\prod_i p_i^{\alpha_i} \tag{4}$$

$$b\equiv\prod_i p_i^{\beta_i}, \tag{5}$$

where the p_is are all PRIME FACTORS of a and b, and if p_i does not occur in one factorization, then the corresponding exponent is taken as 0. Then the greatest common divisor GCD(a, b) is given by

$$\mathrm{GCD}(a, b)=\prod_i p_i^{\min(\alpha_i, \beta_i)}, \tag{6}$$

where min denotes the MINIMUM. For example, consider GCD(12, 30).

$$12=2^2\cdot 3^1\cdot 5^0 \tag{7}$$

$$30=2^1\cdot 3^1\cdot 5^1, \tag{8}$$

so

$$\mathrm{GCD}(12, 30)=2^1\cdot 3^1\cdot 5^0=6. \tag{9}$$

The GCD is DISTRIBUTIVE

$$\mathrm{GCD}(ma, mb)=m\,\mathrm{GCD}(a, b) \tag{10}$$

$$\mathrm{GCD}(ma, mb, mc)=m\,\mathrm{GCD}(a, b, c), \tag{11}$$

and ASSOCIATIVE

$$\begin{aligned}\mathrm{GCD}(a, b, c)&=\mathrm{GCD}(\mathrm{GCD}(a, b), c)\\&=\mathrm{GCD}(a, \mathrm{GCD}(b, c))\end{aligned} \tag{12}$$

$$\begin{aligned}\mathrm{GCD}(ab, cd)&=\mathrm{GCD}(a, c)\mathrm{GCD}(b, d)\\&\times\mathrm{GCD}\left(\frac{a}{\mathrm{GCD}(a, c)}, \frac{d}{\mathrm{GCD}(b, d)}\right)\\&\times\mathrm{GCD}\left(\frac{c}{\mathrm{GCD}(a, c)}, \frac{b}{\mathrm{GCD}(b, d)}\right).\end{aligned} \tag{13}$$

If $a=a_1\mathrm{GCD}(a, b)$ and $b=b_1\mathrm{GCD}(a, b)$, then

$$\begin{aligned}\mathrm{GCD}(a, b)&=\mathrm{GCD}(a_1\,\mathrm{GCD}(a, b), b_1\,\mathrm{GCD}(a, b))\\&=\mathrm{GCD}(a, b)\,\mathrm{GCD}(a_1, b_1),\end{aligned} \tag{14}$$

so $\mathrm{GCD}(a_1, b_1)=1$ and a_1 and b_1 are said to be RELATIVELY PRIME. The GCD is also IDEMPOTENT

$$\mathrm{GCD}(a, a)=a, \tag{15}$$

COMMUTATIVE

$$\mathrm{GCD}(a, b)=\mathrm{GCD}(b, a), \tag{16}$$

and satisfies the ABSORPTION LAW

$$\mathrm{LCM}(a, \mathrm{GCD}(a, b))=a. \tag{17}$$

The probability that two INTEGERS picked at random are RELATIVELY PRIME is $[\zeta(2)]^{-1}=6/\pi^2$, where $\zeta(z)$ is the RIEMANN ZETA FUNCTION. Polezzi (1997) observed that $\mathrm{GCD}(m, n)=k$, where k is the number of LATTICE POINTS in the PLANE on the straight LINE connecting the VECTORS (0, 0) and (m, n) (excluding (m, n) itself). This observation is intimately connected with the probability of obtaining RELATIVELY PRIME integers, and also with the geometric interpretation of a REDUCED FRACTION y/x as a string through a LATTICE of points with ends at (1,0) and (x, y). The pegs it presses against (x_i, y_i) give alternate CONVERGENTS y_i/x_i of the CONTINUED FRACTION for y/x, while the other CONVERGENTS are obtained from the pegs it presses against with the initial end at (0, 1).

Knuth showed that

$$\gcd(2^p - 1,\ 2^q - 1) = 2^{\gcd(p,\ q)} - 1. \qquad (18)$$

The extended greatest common divisor of two INTEGERS m and n can be defined as the greatest common divisor $\text{GCD}(m,\ n)$ of m and n which also satisfies the constraint $\text{GCD}(m,\ n) = rm + sn$ for r and s given INTEGERS. It is used in solving LINEAR DIOPHANTINE EQUATIONS.

Greatest Common Divisor Theorem

Given m and n, it is possible to choose c and d such that $cm + dn$ is a common factor of m and n.

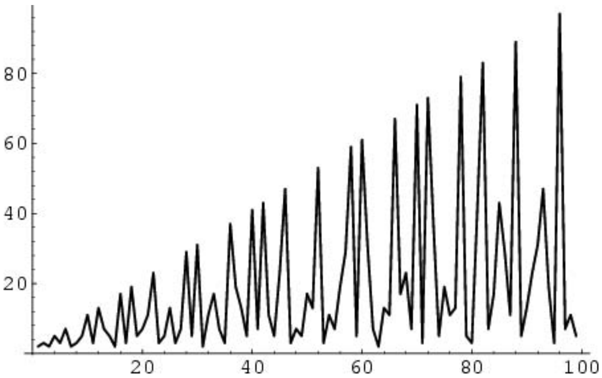
Greatest Common Factor

GREATEST COMMON DIVISOR

Greatest Dividing Exponent

The greatest dividing exponent $\text{gde}(n,\ b)$ of a base b with respect to a number n is the largest integer value of k such that $b^k | n$, where $b^k \le n$. It is implemented as the *Mathematica* command `IntegerExponent[`n`, `b`]`.

See also DIVIDE, EVEN PART, ODD PART



Greatest Integer Function

FLOOR FUNCTION

Greatest Lower Bound

INFIMUM

Greatest Prime Factor

For an INTEGER $n \ge 2$, let $\text{gpf}(x)$ denote the greatest prime factor of n, i.e., the number p_k in the factorization

$$n = p_1^{a_1} \dots p_k^{a_k},$$

with $p_i < p_j$ for $i < j$. For $n = 2, 3, \dots$, the first few are 2, 3, 2, 5, 3, 7, 2, 3, 5, 11, 3, 13, 7, 5, ... (Sloane's A006530). The greatest *multiple* prime factors for SQUAREFUL integers are 2, 2, 3, 2, 2, 3, 2, 2, 5, 3, 2, 2, 3, ... (Sloane's A046028).
The probability that the GREATEST PRIME FACTOR of a RANDOM integer n is greater than $\sqrt{n}$ is $\ln 2$ (Schroeppel 1972).

Grebe Point

SYMMEDIAN POINT

Greedy Algorithm

An algorithm used to recursively construct a SET of objects from the smallest possible constituent parts.

Given a SET of k INTEGERS $(a_1,\ a_2,\ \dots,\ a_k)$ with $a_1 < a_2 < \dots < a_k$, a greedy algorithm can be used to find a

VECTOR of coefficients $(c_1, c_2, ..., c_k)$ such that

$$\sum_{i=1}^{k} c_i a_i = \mathbf{c} \cdot \mathbf{a} = n, \tag{1}$$

where $\mathbf{c} \cdot \mathbf{a}$ is the DOT PRODUCT, for some given INTEGER n. This can be accomplished by letting $c_i = 0$ for $i = 1, ..., k-1$ and setting

$$c_k = \left\lfloor \frac{n}{a_k} \right\rfloor, \tag{2}$$

where $\lfloor x \rfloor$ is the floor function. Now define the difference between the representation and n as

$$\Delta \equiv n - \mathbf{c} \cdot \mathbf{a}. \tag{3}$$

If $\Delta = 0$ at any step, a representation has been found. Otherwise, decrement the NONZERO a_i term with least i, set all $a_j = 0$ for $j < i$, and build up the remaining terms from

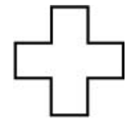
$$c_j = \left\lfloor \frac{\Delta_j}{a_k} \right\rfloor \tag{4}$$

for $j = i-1, ..., 1$ until $\Delta = 0$ or all possibilities have been exhausted.

For example, MCNUGGET NUMBERS are numbers which are representable using only $(a_1, a_2, a_3) = (6, 9, 20)$. Taking $n = 62$ and applying the algorithm iteratively gives the sequence (0, 0, 3), (0, 2, 2), (2, 1, 2), (3, 0, 2), (1, 4, 1), at which point $\Delta = 0$. 62 is therefore a MCNUGGET NUMBER with

$$62 = (1 \cdot 6) + (4 \cdot 9) + (1 \cdot 20). \tag{5}$$

If *any* INTEGER n can be represented with $c_i = 0$ or 1 using a sequence $(a_1, a_2, ...)$, then this sequence is called a COMPLETE SEQUENCE.



A greedy algorithm can also be used to break down arbitrary fractions into UNIT FRACTIONS in a finite number of steps. For a FRACTION a/b, find the least INTEGER x_1 such that $1/x_1 \leq a/b$, i.e.,

$$x_1 = \frac{\lceil b \rceil}{a}, \tag{6}$$

where $\lceil x \rceil$ is the CEILING FUNCTION. Then find the least INTEGER x_2 such that $1/x_2 \leq a/b - 1/x_1$. Iterate until there is no remainder. The ALGORITHM gives two or fewer terms for $1/n$ and $2/n$, three or fewer terms for $3/n$, and four or fewer for $4/n$.

Greek Problems

GEOMETRIC PROBLEMS OF ANTIQUITY

Green Space

A G-SPACE provides local notions of harmonic, hyperharmonic, and superharmonic functions. When there exists a nonconstant superharmonic function greater than 0, it is a called a Green space. Examples are $\mathbb{R}^n$ (for $n \geq 3$) and any bounded domain of $\mathbb{R}^n$.

See also G-SPACE

Green's Function

A Green's function is an integrating kernal which can be used to solve an inhomogeneous differential equation with boundary conditions. It serves roughly an analogous role in partial differential equations as does FOURIER ANALYSIS in the solution of ordinary differential equations.

As a special case, consider the 1-D DIFFERENTIAL OPERATOR

$$\tilde{L} = \tilde{D}^n + a_{n-1}(t)\tilde{D}^{n-1} + \ldots + a_1(t)\tilde{D} + a_0(t), \tag{1}$$

with $a_i(t)$ CONTINUOUS for $i = 0, 1, ..., n-1$ on the interval I, and assume we wish to find the solution $y(t)$ to the equation

$$\tilde{L}y(t) = h(t), \tag{2}$$

where $h(t)$ is a given CONTINUOUS FUNCTION on I. To solve equation (2), we look for a function $g : C^n(I) \mapsto C(I)$ such that $\tilde{L}(g(h)) = h$, where

$$y(t) = g(h(t)). \tag{3}$$

This is a CONVOLUTION equation OF THE FORM

$$y = g * h, \tag{4}$$

so the solution is

$$y(t) = \int_{t_0}^{t} g(t-x)h(x)\,dx, \tag{5}$$

and the function $g(t)$ is called the Green's function for

$\tilde{L}$ on I. Now, note that if we take $h(t)=\delta(t)$, then

$$y(t)=\int_{t_0}^{t} g(t-x)\delta(x)\,dx=g(t), \tag{6}$$

so the Green's function $g(t)$ can be defined by

$$\tilde{L}g(t)=\delta(t). \tag{7}$$

However, the Green's function is determined uniquely only if some initial or boundary conditions are given.

For an arbitrary linear differential operator $\tilde{L}$ in 3-D, the Green's function $G(\mathbf{r}, \mathbf{r}')$ is defined by analogy with the 1-D case by

$$\tilde{L}G(\mathbf{r}, \mathbf{r}')=\delta(\mathbf{r}-\mathbf{r}'). \tag{8}$$

The solution to $\tilde{L}\phi=f$ is then

$$\phi(\mathbf{r})=\int G(\mathbf{r}, \mathbf{r}')f(\mathbf{r}')d^3\mathbf{r}'. \tag{9}$$

Explicit expressions for $G(\mathbf{r}, \mathbf{r}')$ can often be found in terms of a basis of given eigenfunctions $\phi_n(\mathbf{r}_1)$ by expanding the Green's function

$$G(\mathbf{r}_1, \mathbf{r}_2)=\sum_{n=0}^{\infty} a_n(\mathbf{r}_2)\phi_n(\mathbf{r}_1) \tag{10}$$

and DELTA FUNCTION,

$$\delta^3(\mathbf{r}_1-\mathbf{r}_2)=\sum_{n=0}^{\infty} b_n\phi_n(\mathbf{r}_1). \tag{11}$$

Multiplying both sides by $\phi_m(\mathbf{r}_2)$ and integrating over $\mathbf{r}_1$ space,

$$\int \phi_m(\mathbf{r}_2)\delta^3(\mathbf{r}_1-\mathbf{r}_2)d^3\mathbf{r}_1 = \sum_{n=0}^{\infty} b_n \int \phi_m(\mathbf{r}_2)\phi_n(\mathbf{r}_1)d^3\mathbf{r}_1 \tag{12}$$

$$\phi_m(\mathbf{r}_2)=\sum_{n=0}^{\infty} b_n\delta_{nm}=b_m, \tag{13}$$

so

$$\delta^3(\mathbf{r}_1-\mathbf{r}_2)=\sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1)\phi_n(\mathbf{r}_2). \tag{14}$$

By plugging in the differential operator, solving for the a_ns, and substituting into G, the original nonhomogeneous equation then can be solved.

The coefficient S of $\ln(1/r)$ in all normalized fundamental Green's function solutions

$$\phi(x, y; x_0, y_0) = S(x, y; x_0, y_0)\ln(1/r)+T(x, y; x_0, y_0) \tag{15}$$

with

$$r=\sqrt{(x-x_0)^2+(y-y_0)^2} \tag{16}$$

of the ELLIPTIC PARTIAL DIFFERENTIAL EQUATION

$$Ku=u_{xx}+v_{yy}+A(x, y)u_x+B(x, y)u_y+C(x, y)u =0 \tag{17}$$

with analytic coefficients is an analytic function of four variables and is equal to the RIEMANN FUNCTION $S=R^*(\xi, \eta; \xi_0, \eta_0)$ of the conjugate equation

$$K^*v=v(\xi, \eta)-(av)(\xi)-(bv)(\eta)+cv=0 \tag{18}$$

which can be produced from $Ku=0$ by the change of variables

$$\xi=x+iy \tag{19}$$

$$\eta=x-iy \tag{20}$$

$$\xi_0=x_0+iy_0 \tag{21}$$

$$\eta_0=x_0-iy_0 \tag{22}$$

$$4a(\xi, \eta)=A(x, y)+iB(x, y) \tag{23}$$

$$4b(\xi, \eta)=A(x, y)-iB(x, y) \tag{24}$$

$$4c(\xi, \eta)=C(x, y) \tag{25}$$

(Garabedian 1964, Marichev 1990).

Green's Function—Helmholtz Differential Equation

The inhomogeneous HELMHOLTZ DIFFERENTIAL EQUATION is

$$\nabla^2\psi(\mathbf{r})+k^2\psi(\mathbf{r})=\rho(\mathbf{r}), \tag{1}$$

where the Helmholtz operator is defined as $\tilde{L}\equiv\nabla^2+k^2$. The Green's function is then defined by

$$(\nabla^{2+}k^2)G(\mathbf{r}_1, \mathbf{r}_2)=\delta^3(\mathbf{r}_1-\mathbf{r}_2). \tag{2}$$

Define the basis functions ϕ_n as the solutions to the homogeneous HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2\phi_n(\mathbf{r})+k_n^2\phi_n(\mathbf{r})=0. \tag{3}$$

The Green's function can then be expanded in terms

of the ϕ_ns,

$$G(\mathbf{r}_1, \mathbf{r}_2) = \sum_{n=0}^{\infty} a_n(\mathbf{r}_2)\phi_n(\mathbf{r}_1), \tag{4}$$

and the DELTA FUNCTION as

$$\delta^3(\mathbf{r}_1 - \mathbf{r}_2) = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1)\phi_n(\mathbf{r}_2). \tag{5}$$

Plugging (4) and (5) into (2) gives

$$\nabla^2\left[\sum_{n=0}^{\infty} a_n(\mathbf{r}_2)\phi_n(\mathbf{r}_1)\right] + k^2 \sum_{n=0}^{\infty} a_n(\mathbf{r}_2)\phi_n(\mathbf{r}_1) = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1)\phi_n(\mathbf{r}_2). \tag{6}$$

Using (3) gives

$$-\sum_{n=0}^{\infty} a_n(\mathbf{r}_2)k_n^2\phi_n(\mathbf{r}_1) + k^2 \sum_{n=0}^{\infty} a_n(\mathbf{r}_2)\phi_n(\mathbf{r}_1) = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1)\phi_n(\mathbf{r}_2) \tag{7}$$

$$\sum_{n=0}^{\infty} a_n(\mathbf{r}_2)\phi_n(\mathbf{r}_1)(k^2 - k_n^2) = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1)\phi_n(\mathbf{r}_2). \tag{8}$$

This equation must hold true for each n, so

$$a_n(\mathbf{r}_2)\phi_n(\mathbf{r}_1)(k^2 - k_n^2) = \phi_n(\mathbf{r}_1)\phi_n(\mathbf{r}_2) \tag{9}$$

$$a_n(\mathbf{r}_2) = \frac{\phi_n(\mathbf{r}_2)}{k^2 - k_n^2}, \tag{10}$$

and (4) can be written

$$G(\mathbf{r}_1, \mathbf{r}_2) = \sum_{n=0}^{\infty} \frac{\phi_n(\mathbf{r}_1)\phi_n(\mathbf{r}_2)}{k^2 - k_n^2}. \tag{11}$$

The general solution to (1) is therefore

$$\psi(\mathbf{r}_1) = \int G(\mathbf{r}_1, \mathbf{r}_2)\rho(\mathbf{r}_2)d^3\mathbf{r}_2 = \sum_{n=0}^{\infty} \int \frac{\phi_n(\mathbf{r}_1)\phi_n(\mathbf{r}_2)\rho(\mathbf{r}_2)}{k^2 - k_n^2}\, d^3\mathbf{r}_2. \tag{12}$$

Green's Function—Poisson's Equation

POISSON'S EQUATION equation is

$$\nabla^2\phi = 4\pi\rho, \tag{1}$$

where ϕ is often called a potential function and ρ a density function, so the differential operator in this case is $\tilde{L} = \nabla^2$. As usual, we are looking for a Green's function $G(\mathbf{r}_1, \mathbf{r}_2)$ such that

$$\nabla^2 G(\mathbf{r}_1, \mathbf{r}_2) = \delta^3(\mathbf{r}_1, \mathbf{r}_2). \tag{2}$$

But from LAPLACIAN,

$$\nabla^2\left(\frac{1}{|\mathbf{r} - \mathbf{r}'|}\right) = -4\pi\delta^3(\mathbf{r} - \mathbf{r}'), \tag{3}$$

so

$$G(\mathbf{r}, \mathbf{r}') = -\frac{1}{4\pi|\mathbf{r} - \mathbf{r}'|}, \tag{4}$$

and the solution is

$$\phi(\mathbf{r}) = \int G(\mathbf{r}, \mathbf{r}')[4\pi\rho(\mathbf{r}')]d^3\mathbf{r}' = -\int \frac{\rho(\mathbf{r}')d^3\mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|}. \tag{5}$$

Expanding $G(\mathbf{r}_1, \mathbf{r}_2)$ in the SPHERICAL HARMONICS Y_l^m gives

$$G(\mathbf{r}_1, \mathbf{r}_2) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \frac{1}{2l+1} \frac{r_<^l}{r_>^{l+1}} Y_l^m(\theta_1, \phi_1)\bar{Y}_l^m(\theta_2, \phi_2), \tag{6}$$

where $r_<$ and $r_>$ are GREATER THAN/LESS THAN SYMBOLS. this expression simplifies to

$$g(\mathbf{r}_1, \mathbf{r}_2) = \frac{1}{4\pi} \sum_{l=0}^{\infty} \frac{r_<^l}{r_>^{l+1}} p_l(\cos\gamma), \tag{7}$$

where p_l are LEGENDRE POLYNOMIALS, and $\cos\gamma \equiv \mathbf{r}_1 \cdot \mathbf{r}_2$. Equations (6) and (7) give the addition theorem for LEGENDRE POLYNOMIALS.

In CYLINDRICAL COORDINATES, the Green's function is much more complicated,

$$G(\mathbf{r}_1, \mathbf{r}_2) = \frac{1}{2\pi^2} \sum_{m=-\infty}^{\infty} \int_0^{\infty} I_m(k\rho_<)K_m(k\rho_>)e^{im(\phi_1-\phi_2)}\cos[k(z_1 - z_2)]\, dk. \tag{8}$$

where $I_m(x)$ and $K_m(x)$ are MODIFIED BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS (Arfken 1985).

Green's Identities

Green's identities are a set of three vector derivative/integral identities which can be derived starting with the vector derivative identities

$$\nabla \cdot (\psi\nabla\phi) = \psi\nabla^2\phi + (\nabla\psi)\cdot(\nabla\phi) \tag{1}$$

and

$$\nabla \cdot (\phi\nabla\psi) = \phi\nabla^2\psi + (\nabla\phi)\cdot(\nabla\psi), \quad (2)$$

where $\nabla\cdot$ is the DIVERGENCE, ∇ is the GRADIENT, ∇^2 is the LAPLACIAN, and $\mathbf{a}\cdot\mathbf{b}$ is the DOT PRODUCT. From the DIVERGENCE THEOREM,

$$\int_V (\nabla\cdot\mathbf{F})\,dV = \int_S \mathbf{F}\cdot d\mathbf{a}. \quad (3)$$

Plugging (2) into (3),

$$\int_S \phi(\nabla\psi)\cdot d\mathbf{a} = \int_V [\phi\nabla^2\psi + (\nabla\phi)\cdot(\nabla\psi)]\,dV. \quad (4)$$

This is Green's first identity.

Subtracting (2) from (1),

$$\nabla\cdot(\phi\nabla\psi - \psi\nabla\phi) = \phi\nabla^2\psi - \psi\nabla^2\phi. \quad (5)$$

Therefore,

$$\int_V (\phi\nabla^2\psi - \psi\nabla^2\phi)\,dV = \int_S (\phi\nabla\psi - \psi\nabla\phi)\cdot d\mathbf{a}. \quad (6)$$

This is Green's second identity.

Let u have continuous first PARTIAL DERIVATIVES and be HARMONIC inside the region of integration. Then Green's third identity is

$$u(x, y) = \frac{1}{2\pi}\oint_C \left[\ln\left(\frac{1}{r}\right)\frac{\partial u}{\partial n} - u\frac{\partial}{\partial n}\ln\left(\frac{1}{r}\right)\right] ds \quad (7)$$

(Kaplan 1991, p. 361).

Green's Theorem

Green's theorem is a vector identity which is equivalent to the CURL THEOREM in the PLANE. Over a region D in the plane with boundary ∂D,

$$\int_{\partial D} f(x, y)\,dx + g(x, y)\,dy = \int\int_D \left(\frac{\partial g}{\partial x} - \frac{\partial f}{\partial y}\right) dx\,dy$$

$$\int_{\partial D} \mathbf{F}\cdot ds = \int\int_D (\nabla\times\mathbf{F})\cdot\mathbf{k}\,dA.$$

If the region D is on the left when traveling around ∂D, then AREA of D can be computed using

$$A = \tfrac{1}{2}\int_{\partial D} x\,dy - y\,dx.$$

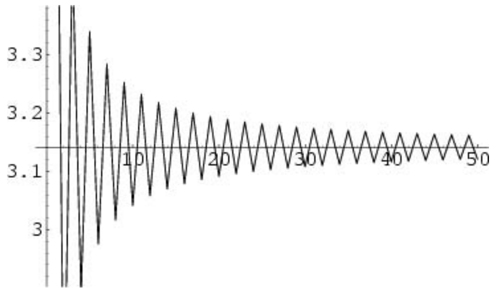
Gregory Number

A number



$$t_x = \tan^{-1}\left(\frac{1}{x}\right) = \cot^{-1} x,$$

where x is an INTEGER or RATIONAL NUMBER, $\tan^{-1} x$ is the INVERSE TANGENT, and $\cot^{-1} x$ is the INVERSE COTANGENT. Gregory numbers arise in the determination of MACHIN-LIKE FORMULAS. Every Gregory number t_x can be expressed uniquely as a sum of t_ns where the ns are STØRMER NUMBERS.

References

Conway, J. H. and Guy, R. K. "Gregory's Numbers" In *The Book of Numbers.* New York: Springer-Verlag, pp. 241–42, 1996.

Gregory's Formula

There are at least two formulas associated with Gregory. The first is a series PI FORMULA found by Gregory and Leibniz and obtained by plugging $x=1$ into the LEIBNIZ SERIES,

$$\frac{\pi}{4}=1-\frac{1}{3}+\frac{1}{5}+\cdots$$

(Wells 1986, p. 50). The formula, also called the LEIBNIZ SERIES, converges very slowly, but its convergence can be accelerated using certain transformations, in particular

$$\pi=\sum_{k=1}^{\infty}\frac{3^k-1}{4^k}\,\zeta(k+1),$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Vardi 1991).
The second is the formula

$$\int_0^y p(u)du=\sum_{k\geq 0}\left\langle\frac{(e^{yt}-1)^k|p(x)\rangle}{k!\,(e^t-1)^k p(x),}\right.$$

discovered by Gregory in 1670 and reported to be the earliest formula in NUMERICAL INTEGRATION (Jordan 1950, Roman 1984).

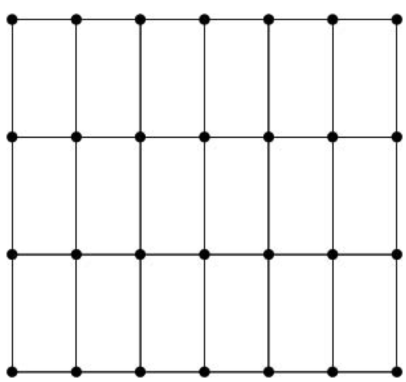
Grid

This entry contributed by DANIEL SCOTT UZNANSKI

A grid usually refers to two or more infinite sets of evenly-spaced parallel lines at particular angles to each other in a plane, or the intersections of such lines. The two most common types of grid are orthogonal grids, with two sets of lines perpendicular to each other, and isometric grids, with three sets of lines at 60-degree angles to each other. It should be

noted that in most grids with three or more sets of lines, every intersection includes one element of each set.



There are other types of planar grids, like hexagonal grids, which are formed by tessellating regular hexagons in the plane. These are often found in strategy and role-playing games because of the lack of single points of contact characteristic of isometric and orthogonal grids. The collection of cells created by a grid is often called a "BOARD" when these cells are used as resting places for pieces in a game.

Grids can be generalized into n-D space by using the centers of packed n-spheres or n-cubes as the points.

Grid Graph

An $m \times n$ grid graph $G_{m,n}$ is the product of PATH GRAPHS on m and n vertices. A grid graph $G_{n,1}$ is called a PATH GRAPH. The grid graph $G_{2,2}$ is the CYCLE GRAPH C_4.

A grid graph is HAMILTONIAN if either the number of rows or columns is even (Skiena 1990, p. 148). Grid graphs are also bipartite (Skiena 1990, p. 148).

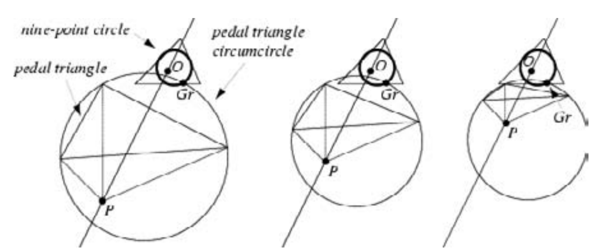
Griffiths Points

"The" Griffiths point Gr is the fixed point in GRIFFITHS' THEOREM. Given four points on a CIRCLE and a line through the center of the CIRCLE, the four corresponding Griffiths points are COLLINEAR (Tabov 1995).

The points

$$Gr = I + 4Ge$$



$$Gr' = I - 4Ge,$$

are known as the first and second Griffiths points, where I is the INCENTER and Ge is the GERGONNE POINT (Oldknow 1996). The Griffiths points lie on the SODDY LINE.

See also GERGONNE POINT, GRIFFITHS' THEOREM, INCENTER, OLDKNOW POINTS, RIGBY POINTS, SODDY LINE

Griffiths' Theorem

When a point P moves along a line through the CIRCUMCENTER of a given TRIANGLE Δ, the PEDAL CIRCLE of P with respect to Δ passes through a fixed point (the GRIFFITHS POINT) on the NINE-POINT CIRCLE of Δ.

See also CIRCUMCENTER, GRIFFITHS POINTS, NINE-POINT CIRCLE, PEDAL CIRCLE

Grimm's Conjecture

Grimm conjectured that if $n+1, n+2, ..., n+k$ are all COMPOSITE NUMBERS, then there are distinct PRIMES p_{i_j} such that $p_{i_j} | (n+j)$ for $1 \leq j \leq k$.

References
Guy, R. K. "Grimm's Conjecture." §B32 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, p. 86, 1994.

Grinberg Formula

A formula satisfied by all HAMILTONIAN CIRCUITS with n nodes. Let f_j be the number of regions inside the circuit with j sides, and let g_j be the number of

regions outside the circuit with j sides. If there are d interior diagonals, then there must be $d+1$ regions

$$[\text{\# regions in interior}] = d+1 = f_2+f_3+\ldots+f_n. \quad (1)$$

Any region with j sides is bounded by j EDGES, so such regions contribute jf_j to the total. However, this counts each diagonal twice (and each EDGE only once). Therefore,

$$2f_2+3f_3+\ldots nf_n = 2d+n. \quad (2)$$

Take (2) minus 2×(1),

$$f_3+2f_4+3f_5+\ldots+(n-2)f_n = n-2. \quad (3)$$

Similarly,

$$g_3+2g_4+\ldots+(n-2)g_n = n-2, \quad (4)$$

so

$$(f_3-g_3)+2(f_4-g_4)+3(f_5-g_5)+\ldots+(n-2)(f_n-g_n) = 0. \quad (5)$$

Gröbner Basis

A Gröbner basis for a system of POLYNOMIALS is an equivalence system that possesses useful properties, for example, that another polynomial f is a combination of those in the system IFF the remainder of f with respect to the system is 0. (Here, the division algorithm requires an ORDER of a certain type on the MONOMIALS.) Furthermore, the set of polynomials in a Gröbner basis have the same collection of roots as the original polynomials. For linear functions in any number of variables, a Gröbner basis is equivalent to GAUSSIAN ELIMINATION.

Gröbner bases are pervasive in the construction of symbolic algebra algorithms, and Gröbner bases with respect to LEXICOGRAPHIC ORDER are very useful for solving equations and for elimination of variables. The algorithm for computing Gröbner bases is known as BUCHBERGER'S ALGORITHM. The determination of a Gröbner basis is very roughly analogous to computing an ORTHONORMAL BASIS from a set of BASIS VECTORS and can be described roughly as a combination of GAUSSIAN ELIMINATION (for linear systems) and the EUCLIDEAN ALGORITHM (for UNIVARIATE POLYNOMIALS over a FIELD).

The time and memory required to calculate a Gröbner basis depend very much on the variable ordering, MONOMIAL ordering, and on which variables are regarded as constants. Gröbner bases are used implicitly in many routines in *Mathematica*, and can be called explicitly with the command `GroebnerBasis[{`*poly1*, *poly2*, ...`}, {`*x1*, *x2*, ...`}]`.

See also BUCHBERGER'S ALGORITHM, COMMUTATIVE ALGEBRA, EUCLIDEAN ALGORITHM, GAUSSIAN ELIMINATION, MONOMIAL, ORTHONORMAL BASIS

Stewart, I. "A Bundling Fool Beats the Wrap." *Sci. Amer.* **268**, 142–44, 1993.

Groemer Theorem

Given n CIRCLES and a PERIMETER p, the total AREA of the CONVEX HULL is

$$A_{\text{Convex Hull}} = 2\sqrt{3}(n-1)+p(1-\tfrac{1}{2}\sqrt{3})+\pi(\sqrt{3}-1)$$

Furthermore, the actual AREA equals this value IFF the packing is a GROEMER PACKING. The theorem was proved in 1960 by Helmut Groemer.

See also CONVEX HULL

Gronwall's Theorem

Let $\sigma(n)$ be the DIVISOR FUNCTION. Then

$$\overline{\lim_{n\to\infty}} \frac{\sigma(n)}{n \ln \ln n} = e^{\gamma},$$

where γ is the EULER-MASCHERONI CONSTANT. Ramanujan independently discovered a less precise version of this theorem (Berndt 1994). Robin (1984) showed that the validity of the inequality

$$\sigma(n) < e^{\gamma} n \ln \ln n$$

for $n \geq 5041$ is equivalent to the RIEMANN HYPOTHESIS.

Grothendieck's Constant

Let A be an $n \times n$ REAL SQUARE MATRIX and let x_i and y_j be real numbers with $|x_i|$, $|y_i|$<0. Then Grothendieck showed that there exists a constant K independent of both A and n satisfying

$$\left| \sum_{1 \leq i, j \leq n} a_{ij} \langle x_i, y_j \rangle \right| \leq K \quad (1)$$

in which the vectors x_i and y_j have a norm < 1 in any HILBERT SPACE. The Grothendieck constant is the smallest REAL NUMBER for which this inequality has been proven. Krivine (1977) showed that

$$1.676\ldots \leq K_G \leq 1.782\ldots, \quad (2)$$

and has postulated that

$$K_G \equiv \frac{\pi}{2 \ln(1+\sqrt{2})} = 1.7822139\ldots, \quad (3)$$

which is related to KHINTCHINE'S CONSTANT.

Grothendieck's Theorem

Let E and F be paired spaces with S a family of absolutely convex bounded sets of F such that the sets of S generate F and, if $B_1, B_2 \in S$, then there exists a $B_3 \in S$ such that $B_3 \supset B_1$ and $B_3 \supset B_2$. Then E_S is complete IFF algebraic linear functional $f(y)$ of F that is weakly continuous on every $B \in S$ is expressed as $f(y) = \langle x, y \rangle$ for some $x \in E$. When E_S is not complete, the space of all linear functionals satisfying this condition gives the completion $\hat{E}_S$ of E_S.

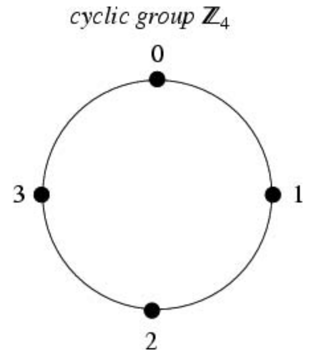
Ground Set

A PARTIALLY ORDERED SET is defined as an ordered pair $P = (X, \leq)$. Here, X is called the GROUND SET of P and $\leq$ is the PARTIAL ORDER of P.

See also PARTIAL ORDER, PARTIALLY ORDERED SET

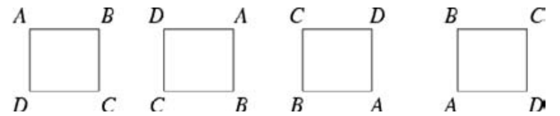
Group



A group G is a finite or infinite set of elements together with a BINARY OPERATION which together satisfy the four fundamental properties of closure, associativity, the identity property, and the inverse property. The operation with respect to which a group is defined is often called the "group operation," and a set is said to be a group "under" this operation. Elements A, B, C, ... with binary operation between A and B denoted AB form a group if

1. Closure: If A and B are two elements in G, then the product AB is also in G.
2. Associativity: The defined multiplication is associative, i.e., for all $A, B, C \in G, (AB)C = A(BC)$.
3. Identity: There is an IDENTITY ELEMENT I (a.k.a. 1, E, or e) such that $IA = AI = A$ for every element $A \in G$.
4. Inverse: There must be an inverse or reciprocal of each element. Therefore, the set must contain an element $B = A^{-1}$ such that $AA^{-1} = A^{-1}A = I$ for each element of G.

A group is therefore a MONOID for which every element is invertible, and a group must contain at least one element.



The study of groups is known as GROUP THEORY. If there are a finite number of elements, the group is called a FINITE GROUP and the number of elements is called the ORDER of the group. A subset of a group that is CLOSED under the group operation and the inverse operation is called a SUBGROUP. SUBGROUPS are also groups, and many commonly encountered groups are in fact special subgroups of some more general larger group.

A basic example of a FINITE GROUP is the SYMMETRIC GROUP Σ_n, which is the group of PERMUTATIONS (or "under permutation") of n objects. The simplest infinite group is the set of INTEGERS under usual ADDITION. For continuous groups, one can consider the real numbers or the set of $n \times n$ invertible MATRICES. These last two are examples of LIE GROUPS.

One very common type of group is the CYCLIC GROUPS. This group is isomorphic to the group of integers (modulo n), is denoted Z_n, $\mathbb{Z}_n$, or $\mathbb{Z}/n\mathbb{Z}$, and is defined for every integer $n > 1$. It is CLOSED under addition, associative, and has unique inverses. The numbers from 0 to $n-1$ represent its elements, with the IDENTITY ELEMENT represented by 0, and the inverse of i is represented by $n - i$.

A map between two groups which preserves the identity and the group operation is called a HOMOMORPHISM. If a homomorphism has an inverse which is also a homomorphism, then it is called an ISOMORPHISM and the two groups are called isomorphic. Two groups which are isomorphic to each other are considered to be "the same" when viewed as abstract groups. For example, the group of rotations of a square, illustrated below, is the CYCLIC GROUP $\mathbb{Z}_4$.

In general, a GROUP ACTION is when a group acts on a set, permuting its elements, so that the map from the group to the PERMUTATION GROUP of the set is a homomorphism. For example, the rotations of a square are a SUBGROUP of the PERMUTATIONS of its corners. One important GROUP ACTION for any group G is its action on itself by CONJUGATION. These are just some of the possible GROUP AUTOMORPHISMS. Another important kind of GROUP ACTION is a REPRESENTATION of a group, where the group acts on a VECTOR SPACE by INVERTIBLE LINEAR MAPS. When the FIELD of the VECTOR SPACE is the complex numbers, sometimes a representation is called a CG MODULE.

GROUP ACTIONS, and in particular representations, are very important in applications, not only to group theory, but also to physics and chemistry. Since a group can be thought of as an abstract mathematical object, the same group may arise in different contexts. It is therefore useful to think of a representation of the group as one particular incarnation of the group, which may also have other representations. An IRREDUCIBLE REPRESENTATION of a group is a representation for which there exists no UNITARY TRANSFORMATION which will transform the represen-

tation MATRIX into block diagonal form. The irreducible representations have a number of remarkable properties, as formalized in the GROUP ORTHOGONALITY THEOREM.

See also GROUP THEORY, SEMIGROUP

Group Action

A GROUP G is said to act on a space X when there is a map $\phi : G \times X \to X$ such that the following conditions hold for all elements $x \in X$.

1. $\phi(e, x) = x$ where e is the identity element of G.
2. $\phi(g, \phi(h, x)) = \phi(gh, x)$ for all $g, h \in G$.

In this case, G is called a TRANSFORMATION GROUP, X is a called a G-set, and ϕ is called the group action.

$$(5\ 7\ 9\ 3\ 4\ 6\ 8\ 2\ 0\ 1)$$

In a group action, a GROUP permutes the elements of X. The identity does nothing, while a composition of actions corresponds to the action of the composition. For example, as illustrated above, the SYMMETRIC GROUP S_{10} acts on the digits 0 to 9 by permutations.

For a given x, the set $\{gx\}$, where the group action moves x, is called the ORBIT of x. The SUBGROUP which fixes x is the ISOTROPY GROUP of x.

For example, the group $\mathbb{Z}_2 = \{[0], [1]\}$ acts on the real numbers by multiplication by $(-1)^n$. The identity leaves everything fixed, while [1] sends x to $(-x)$. Note that $[1] \cdot [1] = [0]$, which corresponds to $-(-x) = x$. For $x \neq 0$, the orbit of x is $\{x, -x\}$, and the isotropy subgroup is trivial, $\{[0]\}$. The only FIXED POINT of this action is $x = 0$.

In a REPRESENTATION, a group acts by invertible LINEAR TRANSFORMATIONS of a VECTOR SPACE V. In fact, a representation is a GROUP HOMOMORPHISM from G to $GL(V)$, the GENERAL LINEAR GROUP of V. Some groups are described in a representation, such as the SPECIAL LINEAR GROUP, although they may have different representations.

Historically, the first group action studied was the action of the GALOIS GROUP on the roots of a POLYNOMIAL. However, there are numerous examples and applications of group actions in many branches of mathematics, including ALGEBRA, TOPOLOGY, GEOMETRY, NUMBER THEORY, and ANALYSIS, as well as the sciences, including chemistry and physics.

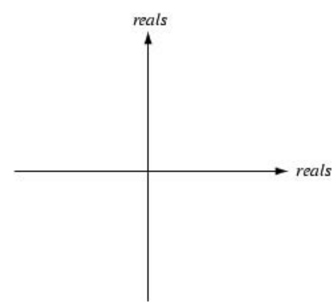
Group Convolution

The convolution of two COMPLEX-valued functions on a GROUP G is defined as



$$(a*b)(g) = \sum_{k \in G} a(k)b(k^{-1}g)$$

where the SUPPORT (set which is not zero) of each function is finite.

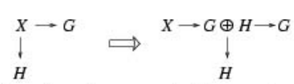
Weinstein, A. "Groupoids: Unifying Internal and External Symmetry." *Not. Amer. Math. Soc.* **43**, 744–52, 1996.

Group Direct Product



Given two GROUPS G and H, there are several ways to form a new group. The simplest is the direct product, denoted $G \times H$. As a set, the group direct product is the CARTESIAN PRODUCT of ordered pairs (g, h), and the group operation is componentwise, so

$$(g_1, h_1) \times (g_2, h_2) = (g_1 g_2, h_1 h_2).$$

For example, $\mathbb{R} \times \mathbb{R}$ is isomorphic to $\mathbb{R}^2$ under VECTOR ADDITION. In a similar fashion, one can take the direct product of any number of groups by taking the Cartesian product and operating componentwise.

Note that G is ISOMORPHIC to the SUBGROUP of elements g, e_H where e_H is the IDENTITY ELEMENT in H. Similarly, H can be realized as a SUBGROUP. The intersection of these two subgroups is the identity (e_G, e_H), and the two subgroups are NORMAL.

the universal property of a direct product; X factors through G ⊕ H.

Like the RING DIRECT PRODUCT, the group direct product has the UNIVERSAL PROPERTY that if any group X has a HOMOMORPHISM to G and a homomorphism to H, then these homomorphisms factor through $G \times H$ in a unique way.

If one has REPRESENTATIONS R_G of G and R_H of H, then there is a representation $R_G \otimes R_H$ sometimes called the EXTERNAL TENSOR PRODUCT, given by the TENSOR PRODUCT $\otimes$. In this case, the group CHARACTER satisfies

$$\chi(g \otimes h) = \chi R_G(g) \chi R_H(h).$$

Riesel, H. "The Direct Product of Two Given Groups." *Prime Numbers and Computer Methods for Factorization, 2nd ed.* Boston, MA: Birkhäuser, pp. 251–52, 1994.

Group Homomorphism

A group homomorphism is a map $f : G \to H$ between two groups such that

1. The group operation is preserved: $f(g_1 g_2) = f(g_1) f(g_2)$
2. The identity is mapped to the identity: $f(e_G) = e_H$,

where the product on the left-hand side is in G and on the right-hand side in H. Note that a homomorphism must preserve the inverse map because $f(g)f(g^{-1}) = f(gg^{-1}) = f(e_G) = e_H$, so $f(g)^{-1} = f(g^{-1})$.

In particular, the image of G is a SUBGROUP of H and the kernel, i.e., $f^{-1}(e_H)$ is a SUBGROUP of G. The kernel is actually a NORMAL SUBGROUP, as is the PREIMAGE of any NORMAL SUBGROUP of H. Hence, any homomorphism from a SIMPLE GROUP must be INJECTIVE.

See also HOMOMORPHISM, GROUP, NORMAL SUBGROUP, REPRESENTATION

Group Orthogonality Theorem

Let Γ be a representation for a GROUP of ORDER h, then

$$\sum_R \Gamma_i(R)_{mn} \Gamma_j(R)_{m'n'}{}^* = \frac{h}{\sqrt{l_i l_j}} \delta_{ij} \delta_{mm'} \delta_{nn'}.$$

The proof is nontrivial and may be found in Eyring *et al.* (1944).

Group Residue Theorem

If two groups are residual to a third, every group residual to one is residual to the other. The Gambier extension of this theorem states that if two groups are pseudoresidual to a third, then every group pseudoresidual to the first with an excess greater than or equal to the excess of the first minus the excess of the second is pseudoresidual to the second, with an excess ≥ 0.

Group Ring

The set of sums $\Sigma_x a_x x$ ranging over a multiplicative GROUP and a_i are elements of a FIELD with all but a finite number of $a_i = 0$. Group rings are GRADED ALGEBRAS.

See also GRADED ALGEBRA

Group Theory

The study of GROUPS. Gauss developed but did not publish parts of the mathematics of group theory, but Galois is generally considered to have been the first to develop the theory. Group theory is a powerful formal method for analyzing abstract and physical systems in which SYMMETRY is present and has surprising importance in physics, especially quantum mechanics.

Groupoid

There are at least two definitions of "groupoid" currently in use.

The first type of groupoid is an algebraic structure on a SET with a BINARY OPERATOR. The only restriction on the operator is closure (i.e., applying the BINARY OPERATOR to two elements of a given set S returns a value which is itself a member of S). Associativity, commutativity, etc., are not required (Rosenfeld 1968, pp. 88–03). A groupoid can be empty. The numbers of nonisomorphic groupoids of this type having n elements are 1, 1, 10, 3330, 178981952, ... (Sloane's A001329), and the numbers of nonisomorphic and nonantiisomorphic groupoids are 1, 7, 1734, 89521056, ... (Sloane's A001424). An associative groupoid is called a SEMIGROUP.

The second type of groupoid is an algebraic structure first defined by Brandt (1926) and also known as a VIRTUAL GROUP. A groupoid with base B is a set G with mappings α and β from G onto B and a partially defined binary operation $(g, h) \mapsto gh$, satisfying the following four conditions:

1. gh is defined only when $\beta(g) = \alpha(h)$ for certain maps α and β from G onto $\mathbb{R}^2$ with $\alpha : (x, \gamma, y) \mapsto x$ and $\beta : (x, \gamma, y) \mapsto y$
2. ASSOCIATIVITY: If either $(gh)k$ or $g(hk)$ is defined, then so is the other and $(gh)k = g(hk)$.
3. For each g in G, there are left and right IDENTITY ELEMENTS λ_g and ρ_g such that $\lambda_g g = g = g\rho_g$.
4. Each g in G has an inverse g^{-1} for which $gg^{-1} = \lambda g$ and $g^{-1}g = \rho g$

(Weinstein 1996). A groupoid is a small CATEGORY with every morphism invertible.

NIM-VALUE

G-Space

A G-space is a special type of HAUSDORFF SPACE. Consider a point x and a HOMEOMORPHISM of an open NEIGHBORHOOD V of x onto an OPEN SET of $\mathbb{R}^n$. Then a space is a G-space if, for any two such NEIGHBORHOODS v' and v'', the images of $v' \cup v''$ under the different HOMEOMORPHISMS are ISOMETRIC. If $n=2$, the HOMEOMORPHISMS need only be conformal (but not necessarily orientation-preserving).

Hsiang (2000, p. 1) terms a space X with a topological (resp. differentiable, linear) transformation of a given GROUP G a topological (resp. differentiable, linear) G-space.

See also GREEN SPACE

References

Hsiang, W. Y. *Lectures on Lie Groups.* Singapore: World Scientific, p. 1, 2000.

G-Transform

The G-transform of a function $f(x)$ is defined by the integral

$$(Gf)(x) = \left(G_{pq}^{mn} \left| \begin{matrix} (a_p) \\ (b_q) \end{matrix} \right| f(t) \right)(x) \tag{1}$$

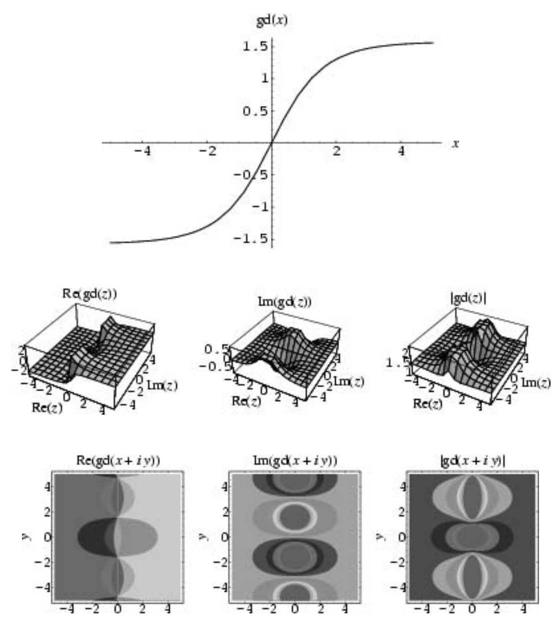
$$= \frac{1}{2\pi i} \int_\sigma \Gamma \begin{bmatrix} (b_m)+s, & 1-(a)_n - s \\ \left(a_p^{n+1}\right)+s, & 1-\left(b_q^{m+1}\right)-s \end{bmatrix} f^*(s) x^{-s}\, ds, \tag{2}$$

where G_{pq}^{mn} is MEIJER'S G-FUNCTION,

$$\Gamma \begin{bmatrix} (b_m)+s, & 1-(a_n)-s \\ \left(a_p^{n+1}\right)+s, & 1-\left(b_q^{m+1}\right)-s \end{bmatrix}$$

$$= \Gamma \begin{bmatrix} b_1+s, & \ldots, & b_m+s, & 1-a_1-s, & \ldots, & 1-a_n-s \\ a_{n+1}+s, & \ldots, & a_p+s, & 1-b_{m+1}-s, & \ldots, & 1-b_q-s \end{bmatrix} \tag{3}$$

$$= \frac{\prod_{j=1}^m \Gamma(b_j+s) \prod_{j=1}^n \Gamma(1-a_j-s)}{\prod_{j=n+1}^p \Gamma(a_j+s) \prod_{j=m+1}^q \Gamma(1-bj-s)}, \tag{4}$$



$f^*(s)$ is the MELLIN TRANSFORM of a function $f(x)$, σ is the CONTOUR $\sigma = \{1/2 - i\infty,\ 1/2 + i\infty\}$, $(a_n) = a_1, a_2, \ldots, a_n$, $(a_p^{n+1}) = a_{n+1}, a_{n+2}, \ldots, a_p$, $(b_m) = b_1, \ldots b_m$, $(b_q^{m+1}) = b_{m+1}, \ldots, b_q$, and the components of the vectors (a_p) and (b_q) are complex numbers satisfying the conditions $\Re[a_p] \neq 1/2, 3/2, 5/2, \ldots$ and $\Re[b_q] \neq -1/2, -3/2, -5/2, \ldots$.

Gudermannian Function

The ODD FUNCTION denoted either $\gamma(x)$ or $\mathrm{gd}(x)$ which arises in the inverse equations for the MERCATOR PROJECTION. $\phi(y) = \mathrm{gd}(y)$ expresses the LATITUDE ϕ in terms of the vertical position y in this projection, so

the Gudermannian function is defined by

$$\mathrm{gd}(x) \equiv \int_0^x \frac{dt}{\cosh t} \tag{1}$$

$$= \tan^{-1}(\sinh x) \tag{2}$$

$$2 \tan^{-1}(e^x) - \tfrac{1}{2}\pi \tag{3}$$

The INVERSE FUNCTION of the Gudermannian function $y = \mathrm{gd}^{-1}\phi$ gives the vertical position y in the MERCATOR PROJECTION in terms of the LATITUDE ϕ, so

$$\mathrm{gd}^{-1}(x) \equiv \int_0^x \frac{dt}{\cos t} \tag{4}$$

$$= \ln[\tan(\tfrac{1}{4}\pi + \tfrac{1}{2}x)] \tag{5}$$

$$= \ln(\sec x + \tan x). \tag{6}$$

The derivatives of the function and its inverse are given by

$$\frac{d}{dx}\,\mathrm{gd}(x) = \operatorname{sech} x \tag{7}$$

$$\frac{d}{dx}\,\mathrm{gd}^{-1}(x) = \sec x. \tag{8}$$

The Gudermannian connects the TRIGONOMETRIC and HYPERBOLIC FUNCTIONS via

$$\sin(\mathrm{gd}\, x) = \tanh x \tag{9}$$

$$\cos(\mathrm{gd}\, x) = \operatorname{sech} x \tag{10}$$

$$\tan(\mathrm{gd}\, x) = \sinh x \tag{11}$$

$$\cot(\mathrm{gd}\, x) = \operatorname{csch} x \tag{12}$$

$$\sec(\mathrm{gd}\, x) = \cosh x \tag{13}$$

$$\csc(\mathrm{gd}\, x) = \coth x. \tag{14}$$

The Gudermannian is related to the EXPONENTIAL FUNCTION by

$$e^x = \sec(\mathrm{gd}\, x) = \tan(\mathrm{gd}\, x) \tag{15}$$

$$= \tan(\tfrac{1}{4}\pi + \tfrac{1}{2}\mathrm{gd}\, x) \tag{16}$$

$$= \frac{1 + \sin(\mathrm{gd}\, x)}{\cos(\mathrm{gd}\, x)} \tag{17}$$

(Beyer 1987, p. 164; Zwillinger 1995, p. 485). Other fundamental identities are

$$\tanh(\tfrac{1}{2}x) = \tan(\tfrac{1}{2}\mathrm{gd}\, x) \tag{18}$$

$$i\, \mathrm{gd}^{-1} x = \mathrm{gd}^{-1}(ix).$$

If $\mathrm{gd}(x + iy) = a + ib$, then

$$\tan a = \frac{\sinh x}{\cos y} \tag{19}$$

$$\tanh b = \frac{\sin y}{\cosh x} \tag{20}$$

$$\tanh x = \frac{\sin a}{\cosh b} \tag{21}$$

$$\tan y = \frac{\sin b}{\cosh a} \tag{22}$$

(Beyer 1987, p. 164; Zwillinger 1995, p. 485).

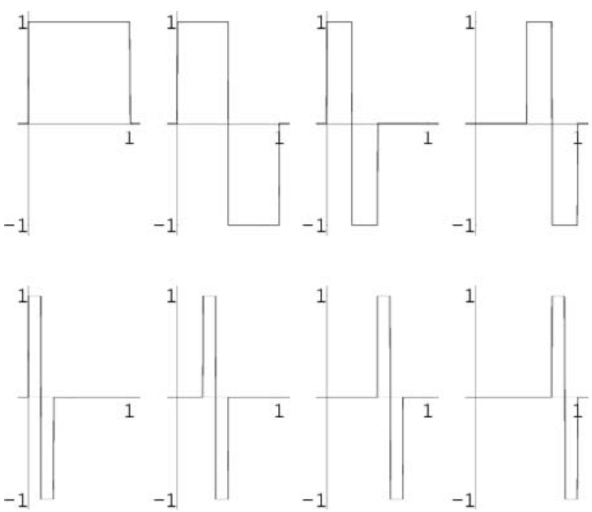
Haar Condition



This entry contributed by RONALD M. AARTS

A set of VECTORS in n-space is said to satisfy the Haar condition if every set of n vectors is LINEARLY INDEPENDENT (Cheney 1999). Expressed otherwise, each selection of n vectors from such a set is a basis for n-space. A system of functions satisfying the Haar condition is sometimes termed a Tchebycheff system (Cheney 1999).

References

Haar Function

Define

$$\psi(x) \equiv \begin{cases} 1 & 0 \le x \le \frac{1}{2} \\ -1 & \frac{1}{2} \le x \le 1 \\ 0 & \text{otherwise} \end{cases} \qquad (1)$$

and

$$\psi_{jk}(x) \equiv \psi\left(2^j x - k\right), \qquad (2)$$

where the FUNCTIONS plotted above are

$$\psi_{00} = \psi(x)$$
$$\psi_{10} = \psi(2x)$$
$$\psi_{11} = \psi(2x-1)$$
$$\psi_{20} = \psi(4x)$$
$$\psi_{21} = \psi(4x-1)$$
$$\psi_{22} = \psi(4x-2)$$
$$\psi_{23} = \psi(4x-3).$$

Then a FUNCTION $f(x)$ can be written as a series expansion by

$$f(x) = c_0 + \sum_{j=0}^{\infty} \sum_{k=0}^{2^j-1} c_{jk}\psi_{jk}(x). \qquad (3)$$

The FUNCTIONS ψ_{jk} and ψ are all ORTHOGONAL in $[0,\ 1]$, with

$$\int_0^1 \phi(x)\phi_{jk}(x)\,dx = 0 \qquad (4)$$

$$\int_0^1 \phi_{jk}(x)\phi_{lm}(x)\,dx = 0. \qquad (5)$$

These functions can be used to define WAVELETS. Let a FUNCTION be defined on n intervals, with n a POWER of 2. Then an arbitrary function can be considered as an n-VECTOR $\mathbf{f}$, and the COEFFICIENTS in the expansion $\mathbf{b}$ can be determined by solving the MATRIX EQUATION

$$\mathbf{f} = \mathsf{W}_n \mathbf{b} \qquad (6)$$

for $\mathbf{b}$, where W is the MATRIX of ψ basis functions. For example, the fourth-order Haar function WAVELET MATRIX is given by

$$W_4 = \begin{bmatrix} 1 & 1 & 1 & 0 \\ 1 & 1 & -1 & 0 \\ 1 & -1 & 0 & 1 \\ 1 & -1 & 0 & -1 \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & -1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

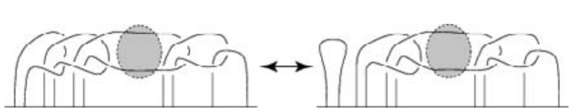
Haberdasher's Problem



With four cuts, DISSECT an EQUILATERAL TRIANGLE into a SQUARE. First proposed by Dudeney (1907) and discussed in Gardner (1961, p. 34), Stewart (1987, p. 169), and Wells (1991, pp. 61–2). The solution can be hinged so that the three pieces collapse into either the TRIANGLE or the SQUARE. Two of the hinges bisect sides of the triangle, while the third hinge and the corner of the large piece on the base cut the base in the approximate ratio 0.982 : 2 : 1.018.

Hadamard Design
A SYMMETRIC BLOCK DESIGN $(4n+3,\ 2n+1,\ n)$ which is equivalent to a HADAMARD MATRIX of order $4n+4$. It is conjectured that Hadamard designs exist for all integers $n>0$, but this has not yet been proven. This elusive proof (or disproof) remains one of the most important unsolved problems in COMBINATORICS.

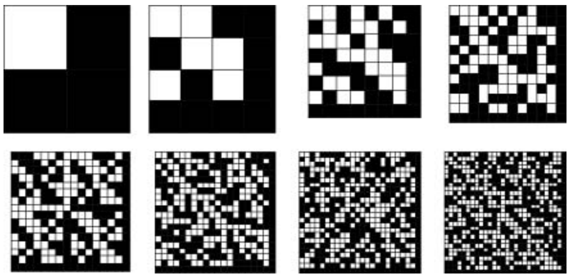
Hadamard Factorization Theorem
Let f be an ENTIRE FUNCTION of FINITE ORDER λ and $\{a_j\}$ the zeros of f, listed with MULTIPLICITY, then the rank p of f is defined as the least positive integer such that

$$\sum_{a_n \neq 0} |a_n|^{-(p+1)} < \infty. \quad (1)$$

Then the canonical Weierstrass product is given by

$$f(z) = e^{g(z)} P(z), \quad (2)$$



and g has degree $q \leq \lambda$. The genus μ of f is then defined as $\max(p,\ q)$, and the Hadamard factorization theory states that an ENTIRE FUNCTION of FINITE ORDER λ is also of finite genus μ, and

$$\mu \leq \lambda. \quad (3)$$

Hadamard Gap Theorem
OSTROWSKI-HADAMARD GAP THEOREM

Hadamard Matrix

A class of SQUARE MATRIX invented by Sylvester (1867) under the name of ANALLAGMATIC PAVEMENT. A Hadamard matrix is a SQUARE MATRIX containing only 1s and -1s such that when any two columns or rows are placed side by side, HALF the adjacent cells are the same SIGN and half the other (excepting from the count an L-shaped "half-frame" bordering the matrix on two sides which is composed entirely of 1s). When viewed as pavements, cells with 1s are colored black and those with -1s are colored white. Therefore, the $n \times n$ Hadamard matrix H_n must have $n(n-1)/2$ white squares (-1s) and $n(n+1)/2$ black squares (1s).

A Hadamard matrix of order n is a solution to HADAMARD'S MAXIMUM DETERMINANT PROBLEM, i.e., has the maximum possible DETERMINANT (in absolute value) of any $n \times n$ COMPLEX MATRIX with elements $|a_{ij}| \leq 1$ (Brenner 1972), namely $n^{n/2}$. An equivalent definition of the Hadamard matrices is given by

$$\mathsf{H}_n \mathsf{H}_n^{\mathrm{T}} = n \mathsf{I}_n, \tag{1}$$

where I_n is the $n \times n$ IDENTITY MATRIX. A Hadamard matrix of order $4n+4$ corresponds to a HADAMARD DESIGN $(4n+3, 2n+1, n)$.

Hadamard (1893) remarked that a NECESSARY condition for a Hadamard matrix to exist is that $n = 1$, 2, or a positive multiple of 4 (Brenner 1972). PALEY'S THEOREM guarantees that there always exists a Hadamard matrix H_n when n is divisible by 4 and OF THE FORM $2^{\epsilon}(p^m + 1)$, where p is an ODD PRIME. In such cases, the MATRICES can be constructed using a PALEY CONSTRUCTION. The PALEY CLASS k is undefined for the following values of $m < 1000$: 92, 116, 156, 172, 184, 188, 232, 236, 260, 268, 292, 324, 356, 372, 376, 404, 412, 428, 436, 452, 472, 476, 508, 520, 532, 536, 584, 596, 604, 612, 652, 668, 712, 716, 732, 756, 764, 772, 808, 836, 852, 856, 872, 876, 892, 904, 932, 940, 944, 952, 956, 964, 980, 988, 996.

Sawade (1985) constructed H_{268}. It is conjectured (and verified up to $n < 428$) that H_n exists for all n DIVISIBLE by 4 (van Lint and Wilson 1993). However, the proof of this CONJECTURE remains an important problem in CODING THEORY. The number of Hadamard matrices of order 4_n are 1, 1, 1, 5, 3, 60, 487, ... (Sloane's A007299).

If H_n and H_m are known, then H_{nm} can be obtained by replacing all 1s in H_m by H_n and all -1s by $-\mathsf{H}_n$. For $n \leq 100$, Hadamard matrices with $n = 12$, 20, 28, 36, 44, 52, 60, 68, 76, 84, 92, and 100 cannot be built up from lower order Hadamard matrices.

$$\mathsf{H}_2 = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \tag{2}$$

$$\mathsf{H}_4 = \begin{bmatrix} \mathsf{H}_2 & \mathsf{H}_2 \\ -\mathsf{H}_2 & \mathsf{H}_2 \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} & \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \\ -\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} & \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ -1 & 1 & -1 & 1 \\ -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 \end{bmatrix}. \tag{3}$$

H_8 can be similarly generated from H_4. Hadamard matrices can also be expressed in terms of the WALSH FUNCTIONS Cal and Sal

$$\mathsf{H}_8 = \begin{bmatrix} \mathrm{Cal}(0,\ t) \\ \mathrm{Sal}(4,\ t) \\ \mathrm{Sal}(2,\ t) \\ \mathrm{Cal}(2,\ t) \\ \mathrm{Sal}(1,\ t) \\ \mathrm{Cal}(3,\ t) \\ \mathrm{Cal}(1,\ t) \\ \mathrm{Sal}(3,\ t) \end{bmatrix}. \tag{4}$$

Hadamard matrices can be used to make ERROR-CORRECTING CODES.

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 6th ed.* San Diego, CA: Academic Press, p. 1110, 2000.

Hadamard's Maximum Determinant Problem

Find the largest possible DETERMINANT (in absolute value) for any $n \times n$ matrix whose elements are taken from some set. Hadamard (1893) proved that the DETERMINANT of any COMPLEX $n \times n$ matrix $\mathbf{A}$ with entries in the closed UNIT DISK $|a_{ij}| \leq 1$ satisfies

$$|\det A| \leq n^{n/2}, \tag{1}$$

with equality attained by the VANDERMONDE MATRIX of the n ROOTS OF UNITY (Faddeev and Sominskii 1965, p. 331; Brenner 1972). The first few values for $\max(\det A_n)$ for $n = 1, 2, \ldots$ are 1, 2, $3\sqrt{3}$, 16, $25\sqrt{5}$, 216, ..., and the squares of these are 1, 4, 27, 256, 3125, ... (Sloane's A000312). A matrix having such a maximal determinant is known as a HADAMARD MATRIX (Brenner 1972).

For real entries, Hadamard's bound can be improved for real matrices to

$$|\det A| \leq \frac{(n+1)^{(n+1)/2}}{2^n} \tag{2}$$

(Faddeev and Sominskii 1965, problem 523; Brenner 1972).

For an $n \times n$ BINARY MATRIX, i.e., a (0,1)-matrix, the largest possible determinants β_n for $n = 1, 2, \ldots$ are 1, 1, 2, 3, 5, 9, 32, 56, 144, 320, 1458, 3645, 9477, ... (Sloane's A003432). The numbers of distinct $n \times n$ binary matrices having the largest possible determinant are 1, 3, 3, 60, ... (Sloane's A051752).

n	matrices
1	$[1]$
2	$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$
3	$\begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix}, \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{bmatrix}$

For an $n \times n$ $(-1, 1)$-matrix, the largest possible determinants α_n for $n = 1, 2, \ldots$ are 1, 2, 4, 16, 48, 160, ... (Sloane's A003433; Ehrlich and Zeller 1962, Ehrlich 1964). The numbers of distinct $n \times n$ $(-1, 1)$-matrices having the largest possible determinant are 1, 4, 96, 384, ... α_n is related to the largest possible $(0, 1)$-matrix determinant β_{n-1} by

$$\alpha_n = 2^{n-1}\beta_{n-1} \quad (3)$$

(Williamson 1946, Brenner 1972).

n	matrices
1	$[1]$
2	$\begin{bmatrix}-1 & -1\\ 1 & -1\end{bmatrix}, \begin{bmatrix}-1 & 1\\ -1 & -1\end{bmatrix}, \begin{bmatrix}1 & -1\\ 1 & -1\end{bmatrix}, \begin{bmatrix}1 & 1\\ -1 & 1\end{bmatrix}$

For an $n \times n$ $(-1, 0, 1)$-matrix, the largest possible determinants γ_n are the same as α_n (Ehrlich 1964, Brenner 1972). The numbers of $n \times n$ $(-1, 0, 1)$-matrices having maximum determinants are 1, 4, 240, ... (Sloane's A051753).

Hadamard-Vallée Poussin Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

The sum of RECIPROCALS of PRIMES diverges, but

$$\lim_{n\to\infty}\left[\sum_{k=1}^{\pi(n)} \frac{1}{p_k} - \ln(\ln n)\right] = \gamma + \sum_{k=1}^{\infty}\left[\ln\left(1-\frac{1}{p_k}\right)+\frac{1}{p_k}\right] \equiv C_1 = 0.2614972128\ldots, \quad (1)$$

where $\pi(n)$ is the PRIME COUNTING FUNCTION and γ is the EULER-MASCHERONI CONSTANT (Le Lionnais 1983). Hardy and Wright (1985) show that, if $\omega(n)$ is the number of distinct PRIME FACTORS of n, then

$$\lim_{n\to\infty}\left[\frac{1}{n}\sum_{k=1}^{n}\omega(k) - \ln(\ln n)\right] = C_1. \quad (2)$$

Furthermore, if $\Omega(n)$ is the total number of PRIME FACTORS of n, then

$$\lim_{n\to\infty}\left[\frac{1}{n}\sum_{k=1}^{n}\Omega(k) - \ln(\ln n)\right] = C_1 + \sum_{k=1}^{\infty}\frac{1}{p_k(p_k-1)} = 1.0346538819\ldots\ . \quad (3)$$

Similarly,

$$\lim_{n\to\infty}\left(\sum_{k=1}^{\pi(n)}\frac{\ln p_k}{p_k} - \ln n\right) = -\gamma - \sum_{j=2}^{\infty}\sum_{k=1}^{\infty}\frac{\ln p_k}{p_k^j} \equiv -C_2 = -1.3325822757\ldots\ . \quad (4)$$

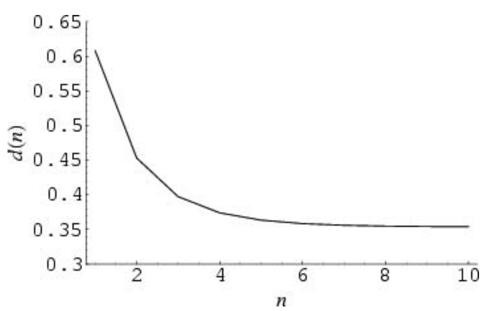
Hadwiger Problem

What is the largest number of subcubes (not necessarily different) into which a CUBE cannot be divided by plane cuts? The answer is 47.

See also CUBE DISSECTION, CUTTING

Hadwiger's Principal Theorem

The VECTORS $\pm\mathbf{a}_1$, ..., $\pm\mathbf{a}_n$ in a 3-space form a normalized EUTACTIC STAR IFF $T\mathbf{x}=\mathbf{x}$ for all $\mathbf{x}$ in the 3-space.



Hafner-Sarnak-McCurley Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Given two randomly chosen $n\times n$ INTEGER MATRICES, what is the probability $D(n)$ that the corresponding DETERMINANTS are RELATIVELY PRIME? Hafner *et al.* (1993) showed that

$$D(n)=\prod_{k=1}^{\infty}\left\{1-\left[1-\prod_{j=1}^{n}\left(1-p_k^{-j}\right)\right]^2\right\}, \tag{1}$$

where p_n is the nth PRIME.

The case D_1 is just the probability that two random INTEGERS are RELATIVELY PRIME,

$$D(1)=\frac{6}{\pi^2}=0.6079271019\ldots \tag{2}$$

No analytic results are known for $n\geq 2$. Approximate values for the first few n are given by

$$D(2)\approx 0.453103 \tag{3}$$

$$D(3)\approx 0.397276 \tag{4}$$

$$D(4)\approx 0.373913 \tag{5}$$

$$D(5)\approx 0.363321. \tag{6}$$

Vardi (1991) computed the limit

$$\sigma\equiv\lim_{n\to\infty} D(n)=0.3532363719\ldots. \tag{7}$$

The speed of convergence is roughly $\sim 0.57^n$ (Flajolet and Vardi 1996).

Hahn Polynomial

The orthogonal polynomials defined by

$$h_n^{(\alpha,\beta)}(x,N)=\frac{(-1)^n(N-x-n)_n(\beta+x+1)_n}{n!}\times{}_3F_2\left(\begin{matrix}-n,-x,\ \alpha+N-x\\ N-x-n,-\beta-x-n\end{matrix};\ 1\right) \tag{1}$$

$$=\frac{(-1)^n(N-n)_n(\beta+1)_n}{n!}\times{}_3F_2\left(\begin{matrix}-n,-x,\ \alpha+\beta+n+1\\ \beta+1,\ 1-N\end{matrix};\ 1\right), \tag{2}$$

where $(x)_n$ is the POCHHAMMER SYMBOL and ${}_3F_2(a,b,c;d,e;z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION (Koepf 1998). The first few are given by

$$h_0^{(\alpha,\beta)}(x,N)=1$$

$$h_1^{(\alpha,\beta)}(x,N)=x(\alpha+\beta+2)-(N-1)(\beta+1).$$

Koekoek and Swarttouw (1998) define another Hahn polynomial

$$Q_n(x;\ \alpha,\ \beta,\ N)={}_3F_2\left(\begin{matrix}-n,\ n+\alpha+\beta+1,-x\\ \alpha+1,-N\end{matrix};\ 1\right), \tag{3}$$

the dual Hahn polynomial

$$R_n(\lambda(x);\ \gamma,\ \delta,\ N)={}_3F_2\left(\begin{matrix}-n,-x,\ x+\gamma+\delta+1\\ \gamma+1,-N\end{matrix};\ 1\right), \tag{4}$$

the continuous Hahn polynomial

$$p_n(x;\ a,\ b,\ c,\ d)=i^n\,\frac{(a+c)_n(a+d)_n}{n!}$$

$$\times {}_3F_2\left(\begin{matrix} -n,\ n+a+b+c+d-1,\ a+ix \\ a+c,\ a+d \end{matrix};\ 1\right), \quad (5)$$

and the continuous dual Hahn polynomial

$$\frac{S_n(x^2;\ a,\ b,\ c)}{(a+b)_n(a+c)_n} = {}_3F_2\left(\begin{matrix} -n,\ a+ix,\ a-ix \\ a+b,\ a+c \end{matrix};\ 1\right), \quad (6)$$

for $n = 0, 1, \ldots, N$, and where

$$\lambda(x) = x(x+\gamma+\delta+1). \quad (7)$$

Hailstone Number

Sequences of INTEGERS generated in the COLLATZ PROBLEM. For example, for a starting number of 7, the sequence is 7, 22, 11, 34, 17, 52, 26, 13, 40, 20, 10, 5, 16, 8, 4, 2, 1, 4, 2, 1, ... Such sequences are called hailstone sequences because the values typically rise and fall, somewhat analogously to a hailstone inside a cloud.

While a hailstone eventually becomes so heavy that it falls to ground, every starting INTEGER ever tested has produced a hailstone sequence that eventually drops down to the number 1 and then "bounces" into the small loop 4, 2, 1, ...

Half

The UNIT FRACTION 1/2.

See also QUARTER, SQUARE ROOT, UNIT FRACTION

Half-Angle Formulas

Formulas expressing trigonometric functions of an angle $x/2$ in terms of functions of an angle x,

$$\sin\left(\tfrac{1}{2}x\right) = \pm\sqrt{\frac{1-\cos x}{2}} \quad (1)$$

$$\cos\left(\tfrac{1}{2}x\right) = \pm\sqrt{\frac{1+\cos x}{2}} \tag{2}$$

$$\tan\left(\tfrac{1}{2}x\right) = \frac{\sin x}{1+\cos x} \tag{3}$$

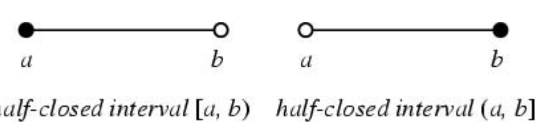
$$= \frac{1-\cos x}{\sin x} \tag{4}$$

$$= \frac{1 \pm \sqrt{1+\tan^2 x}}{\tan x} \tag{5}$$

$$= \frac{\tan x \sin x}{\tan x + \sin x}. \tag{6}$$

The corresponding hyperbolic function double-angle formulas are

$$\sinh\left(\tfrac{1}{2}x\right) = \operatorname{sgn} x\sqrt{\frac{\cosh x - 1}{2}} \tag{7}$$

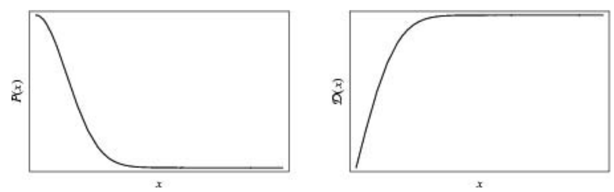


$$\cosh\left(\tfrac{1}{2}x\right) = \sqrt{\frac{\cosh x + 1}{2}} \tag{8}$$

$$\tanh\left(\tfrac{1}{2}x\right) = \frac{\sinh x}{\cosh x + 1} \tag{9}$$

$$= \frac{\cosh x - 1}{\sinh x}. \tag{10}$$

See also DOUBLE-ANGLE FORMULAS, HYPERBOLIC FUNCTIONS, MULTIPLE-ANGLE FORMULAS, PROSTHAPHAERESIS FORMULAS, TRIGONOMETRIC ADDITION FORMULAS, TRIGONOMETRIC FUNCTIONS, TRIGONOMETRY



Half-Closed Interval

An INTERVAL in which one endpoint is included but not the other. A half-closed interval is denoted $[a, b)$ or $(a, b]$ and is also called a HALF-OPEN INTERVAL. The non-standard notation $[a, b[$ and $]a, b]$ is sometimes also used.

See also CLOSED INTERVAL, INTERVAL, OPEN INTERVAL

Half-Normal Distribution

A NORMAL DISTRIBUTION with MEAN 0 and STANDARD DEVIATION $1/\theta$ limited to the domain $x \in [0, \infty)$.

$$P(x) = \frac{2\theta}{\pi} e^{-x^2\theta^2/\pi} \tag{1}$$

$$D(x) = \operatorname{erf}\left(\frac{\theta x}{\sqrt{\pi}}\right). \tag{2}$$

The MOMENTS are

$$\mu_1 = \frac{1}{\theta} \tag{3}$$

$$\mu_2 = \frac{\pi}{2\theta^2} \tag{4}$$

$$\mu_3 = \frac{\pi}{\theta^3} \tag{5}$$

$$\mu_4 = \frac{3\pi^2}{4\theta^4}, \tag{6}$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \frac{1}{\theta} \tag{7}$$

$$\sigma^2 = \frac{\pi - 2}{2\theta^2} \tag{8}$$

$$\gamma_1 = 2\sqrt{\frac{2}{\pi}} \tag{9}$$

$$\gamma_2 = 0. \tag{10}$$

See also NORMAL DISTRIBUTION

Half-Open Interval

HALF-CLOSED INTERVAL

Half-Period Ratio

The ratio $\tau = \omega_1/\omega_2$ of the two half-periods ω_1 and ω_2 of an ELLIPTIC FUNCTION (Whittaker and Watson 1990, p. 475). The notation t is sometimes used instead of τ. The half-period ratio is most commonly encountered in the definition of the NOME q as

$$q(k) \equiv e^{\pi i \tau} = e^{-\pi K'(k)/K(k)} = e^{-\pi K\left(\sqrt{1-k^2}\right)/K(k)} \quad (1)$$

(Borwein and Borwein 1987, pp. 41, 109, and 114; Whittaker and Watson 1990, p. 463) where $K(k)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND, $m = k^2$ is the PARAMETER, k is the MODULUS, $K'(k) = K(k')$, and k' is the complementary MODULUS.

τ is defined such that the IMAGINARY PART $\Im[\tau] > 0$.

Half-Plane

This entry contributed by DANIEL SCOTT UZNANSKI

A half-plane is a planar region consisting of all points on one side of an infinite straight line, and no points on the other side.

See also HALF-SPACE, LOWER HALF-PLANE, PLANE, UPPER HALF-PLANE

Half-Space

A half-space is that portion of an n-dimensional SPACE obtained by removing that part lying on one side of an $(n-1)$-dimensional hyperplane. For example, half a Euclidean space is given by the 3-dimensional region satisfying $x > 0$, $-\infty < y < \infty$, $-\infty < z < \infty$, while a HALF-PLANE is given by the 2-dimensional region satisfying $x > 0$, $-\infty < y < \infty$.

See also HALF-PLANE, SIEGEL'S UPPER HALF-SPACE

Half-Turn

A ROTATION through $180°$ (π radians).

See also ROTATION

References

Coxeter, H. S. M. and Greitzer, S. L. "Half-Turn." §4.3 in *Geometry Revisited.* Washington, DC: Math. Assoc. Amer., pp. 85–6, 1967.

Hall's Theorem

There exists a system of distinct representatives for a family of sets S_1, S_2, ..., S_m IFF the union of any k of these sets contains at least k elements for all k from 1 to m (Harary 1994, p. 53).

References

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, 1994.

Halley's Irrational Formula

A ROOT-finding ALGORITHM which makes use of a third-order TAYLOR SERIES

$$f(x) = f(x_n) + f'(x_n)(x - x_n) + \tfrac{1}{2} f''(x_n)(x - x_n)^2 + \ldots. \quad (1)$$

A ROOT of $f(x)$ satisfies $f(x) = 0$, so

$$0 \approx f(x_n) + f'(x_n)(x_{n+1} - x_n) + \tfrac{1}{2} f''(x_n)(x_{n+1} - x_n)^2. \quad (2)$$

Using the QUADRATIC EQUATION then gives

$$x_{n+1} = x_n + \frac{-f'(x_n) \pm \sqrt{[f'(x_n)]^2 - 2f(x_n)f''(x_n)}}{f''(x_n)}. \quad (3)$$

Picking the plus sign gives the iteration function

$$C_f(x) = x - \frac{1 - \sqrt{1 - \frac{2f(x)f''(x)}{[f'(x)]^2}}}{\frac{f''(x)}{f'(x)}}. \quad (4)$$

This equation can be used as a starting point for deriving HALLEY'S METHOD.

If the alternate form of the QUADRATIC EQUATION is used instead in solving (2), the iteration function becomes instead

$$C_f(x) = x - \frac{2f(x)}{f'(x) \pm \sqrt{[f'(x)]^2 - 2f(x)f''(x)}}. \quad (5)$$

This form can also be derived by setting $n = 2$ in LAGUERRE'S METHOD. Numerically, the SIGN in the DENOMINATOR is chosen to maximize its ABSOLUTE VALUE. Note that in the above equation, if $f''(x) = 0$, then NEWTON'S METHOD is recovered. This form of Halley's irrational formula has cubic convergence, and is usually found to be substantially more stable than NEWTON'S METHOD. However, it does run into difficulty when both $f(x)$ and $f'(x)$ or $f'(x)$ and $f''(x)$ are simultaneously near zero.

See also HALLEY'S METHOD, HOUSEHOLDER'S METHOD, LAGUERRE'S METHOD, NEWTON'S METHOD

Qiu, H. "A Robust Examination of the Newton-Raphson Method with Strong Global Convergence Properties." Master's Thesis. University of Central Florida, 1993.

Scavo, T. R. and Thoo, J. B. "On the Geometry of Halley's Method." *Amer. Math. Monthly* **102**, 417–26, 1995.

Halley's Method

Also known as the TANGENT HYPERBOLAS METHOD or HALLEY'S RATIONAL FORMULA. As in HALLEY'S IRRATIONAL FORMULA, take the second-order TAYLOR POLYNOMIAL

$$f(x) = f(x_n) + f'(x_n)(x - x_n) + \tfrac{1}{2} f''(x_n)(x - x_n)^2 + \dots \quad (1)$$

A ROOT of $f(x)$ satisfies $f(x) = 0$, so

$$0 \approx f(x_n) + f'(x_n)(x_{n+1} - x_n) + \tfrac{1}{2} f''(x_n)(x_{n+1} - x_n)^2. \quad (2)$$

Now write

$$0 = f(x_n) + (x_{n+1} - x_n) \times \left[f'(x_n) + \tfrac{1}{2} f''(x_n)(x_{n+1} - x_n) \right], \quad (3)$$

giving

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n) + \frac{1}{2} f''(x_n)(x_{n+1} - x_n)}. \quad (4)$$

Using the result from NEWTON'S METHOD,

$$x_{n+1} - x_n = -\frac{f(x_n)}{f'(x_n)}. \quad (5)$$

gives

$$x_{n+1} = x_n - \frac{2 f(x_n) f'(x_n)}{2[f'(x_n)]^2 - f(x_n) f''(x_n)}, \quad (6)$$

so the iteration function is

$$H_f(x) = x - \frac{2 f(x) f'(x)}{2[f'(x)]^2 - f(x) f''(x)}. \quad (7)$$

This satisfies $H_f'(\alpha) = H_f''(\alpha) = 0$ where α is a ROOT, so it is third order for simple zeros. Curiously, the third derivative

$$H_f'''(\alpha) = -\left\{ \frac{f'''(\alpha)}{f'(\alpha)} - \frac{3}{2} \left[\frac{f''(\alpha)}{f'(\alpha)} \right]^2 \right\} \quad (8)$$

is the SCHWARZIAN DERIVATIVE. Halley's method may also be derived by applying NEWTON'S METHOD to $f f'^{-1/2}$. It may also be derived by using an OSCULATING CURVE OF THE FORM

$$y(x) = \frac{(x - x_n) + c}{a(x - x_n) + b}. \quad (9)$$

Taking derivatives,

$$f(x_n) = \frac{c}{b} \quad (10)$$

$$f'(x_n) = \frac{b - ac}{b^2} \quad (11)$$

$$f''(x_n) = \frac{2a(ac - b)}{b^3}, \quad (12)$$

which has solutions

$$a = -\frac{f''(x_n)}{2[f'(x_n)]^2 - f(x_n) f''(x_n)} \quad (13)$$

$$b = \frac{2 f'(x_n)}{2[f'(x_n)]^2 - f(x_n) f''(x_n)} \quad (14)$$

$$c = \frac{2 f(x_n) f'(x_n)}{2[f'(x_n)]^2 - f(x_n) f''(x_n)}, \quad (15)$$

so at a ROOT, $y(x_{n+1}) = 0$ and

$$x_{n+1} = x_n - c, \quad (16)$$

which is Halley's method.

HALLEY'S METHOD

Hall-Janko Group

The SPORADIC GROUP HJ, also denoted J_2.

See also JANKO GROUPS

Hall-Littlewood Polynomial

Let n be an integer such that $n \geq \lambda_1$, where $\lambda = (\lambda_1, \lambda_2, \dots)$ is a PARTITION of $n = |\lambda|$ if $\lambda_1 \geq \lambda_2 \geq \dots \geq 0$, where λ_i are a sequence of positive integers stabilizing 0 such that $\Sigma_i \lambda_i = n$. Also let $m_i(\lambda)$ be the number of parts of λ of size i. Then the PERMUTATION $w \in S_n$, where S_n is the symmetric group, acts on the variables x_1, ..., x_n by sending x_i to $x_{w(i)}$. Letting t be a COMPLEX NUMBER, the Hall-Littlewood polynomials are defined by

$$P_\lambda(x_1, \ldots, x_n; t)$$
$$= \frac{1}{\prod_{i\geq 0} \prod_{r=1}^{m_i(\lambda)} \frac{1-t^r}{1-t}} \sum_{w\in S_n} w\left(x_1^{\lambda_1}\cdots x_n^{\lambda_n} \prod_{i<j} \frac{x_i - tx_j}{x_i - x_j}\right).$$

These polynomials interpolate between the Schur functions (with $t=0$) and the monomial symmetric functions (with $t=1$; Fulman 1999).

Hamburger Moment Problem

This entry contributed by RONALD M. AARTS

A NECESSARY and SUFFICIENT condition that there should exist at least one nondecreasing function $\alpha(t)$ such that

$$\mu_n = \int_{-\infty}^{\infty} t^n \, d\alpha(t)$$

for $n=0, 1, 2, \ldots$, with all the integrals converging, is that sequence $\{\mu_n\}_0^\infty$ is positive (Widder 1941, p. 129).

References

Widder, D. V. *The Laplace Transform.* Princeton, NJ: Princeton University Press, 1941.

Hamel Basis

This entry contributed by KEVIN O'BRYANT

A basis for the real numbers $\mathbb{R}$, considered as a VECTOR SPACE over the rationals $\mathbb{Q}$, i.e., a set of real numbers $\{U_\alpha\}$ such that every real number β has a unique representation of the form

$$\beta = \sum_{i=1}^{n} r_i U_{\alpha i},$$

where r_i is rational and n depends on β.

The AXIOM OF CHOICE is equivalent to the statement: "Every VECTOR SPACE has a BASIS," and this is the only justification for the existence of a Hamel basis.

See also AXIOM OF CHOICE, BASIS, BASIS (VECTOR SPACE)

Hamilton's Equations

The equations defined by

$$\dot{q} = \frac{\partial H}{\partial p} \tag{1}$$

$$\dot{p} = -\frac{\partial H}{\partial q} \tag{2}$$

where $\dot{x} \equiv dx/dt$ and H is the so-called Hamiltonian, are called Hamilton's equations. These equations frequently arise in problems of celestial mechanics.

The vector form of these equations is

$$\dot{x}_i = H_{p_i}(t,\ \mathbf{x},\ \mathbf{p}) \tag{3}$$

$$\dot{p}_i = H_{x_i}(t,\ \mathbf{x},\ \mathbf{p}) \tag{4}$$

(Zwillinger 1997, p. 136; Iyanaga and Kawada 1980, p. 1005).

Another formulation related to Hamilton's equation is

$$p = \frac{\partial L}{\partial \dot{q}}, \tag{5}$$

where L is the so-called Lagrangian.

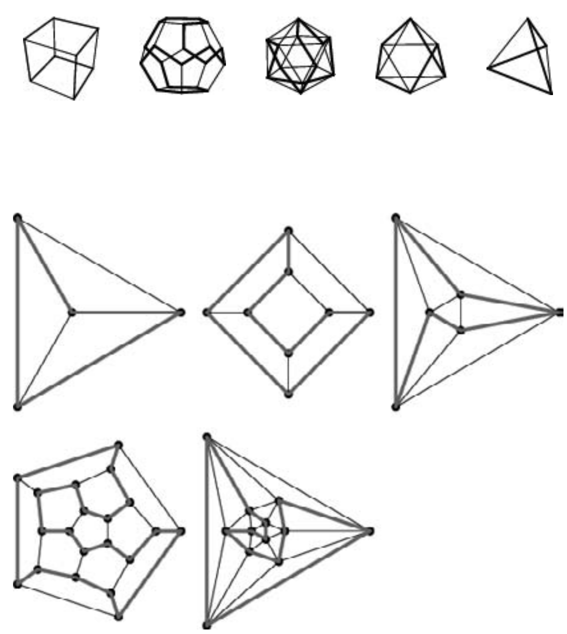
Hamilton's Rules

The rules for the MULTIPLICATION of QUATERNIONS.

See also QUATERNION

Hamilton-Connected Graph

A graph G is Hamilton-connected if every two vertices of G are connected by a HAMILTONIAN PATH (Bondy and Murty 1976, p. 61). All COMPLETE GRAPHS are Hamilton-connected. The numbers of Hamilton-connected simple graphs on $n = 1, 2, \ldots$ nodes are 1, 1, 1, 1, 3, 13, 116, ... (Sloane's A057865).



See also HAMILTONIAN GRAPH, HAMILTONIAN PATH, HYPOTRACEABLE GRAPH, TRACEABLE GRAPH

Hamiltonian Circuit

A GRAPH CYCLE (i.e., closed loop) through a GRAPH that visits each node exactly once (Skiena 1990, p. 196). A graph possessing a Hamiltonian circuit is said to be a HAMILTONIAN GRAPH. The Hamiltonian circuit is named after Sir William Rowan Hamilton, who devised a puzzle in which such a path along the EDGES of an ICOSAHEDRON was sought (the ICOSIAN GAME).

All PLATONIC SOLIDS have a Hamiltonian circuit, as illustrated above.

Although not explicitly stated by Gardner (1957), all ARCHIMEDEAN SOLIDS have Hamiltonian circuits as well, several of which are illustrated above. The Archimedean dual RHOMBIC DODECAHEDRON is Hamiltonian (Gardner 1984, p. 98). All PLANAR 4-connected graphs also have Hamiltonian circuits.

The number of Hamiltonian circuits on an n-HYPERCUBE is 2, 8, 96, 43008, ... (Sloane's A006069; Gardner 1986, pp. 23–4).

In general, the problem of finding a Hamiltonian circuit is NP-COMPLETE (Garey and Johnson 1983), so the only known way to determine whether a given general GRAPH has a Hamiltonian circuit is to undertake an exhaustive search.

Hamiltonian Cycle

HAMILTONIAN CIRCUIT

Hamiltonian Graph

A GRAPH possessing a HAMILTONIAN CIRCUIT. By convention, the trivial graph on a single node is considered Hamiltonian, but the connected graph on two nodes is not. The numbers of simple Hamiltonian graphs on n nodes for $n = 1, 2, \ldots$ are then 1, 0, 1, 3, 8, 48, 383, ... (Sloane's A003216).

Testing whether a graph is Hamiltonian is an NP-COMPLETE PROBLEM (Skiena 1990, p. 196). An algorithm to test graphs is implemented as `HamiltonianQ[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

All Hamiltonian graphs are BICONNECTED, although the converse is not true (Skiena 1990, p. 197). If the sums of the degrees of nonadjacent vertices in a graph G is greater than the number of nodes n for all subsets of nonadjacent vertices, then G is Hamiltonian (Ore 1960; Skiena 1990, p. 197).

Hamiltonian Map

Consider a 1-D Hamiltonian MAP OF THE FORM

$$H(p,\ q)=\tfrac{1}{2}p^2+V(q), \tag{1}$$

which satisfies HAMILTON'S EQUATIONS

$$\dot q=\frac{\partial H}{\partial p} \tag{2}$$

$$\dot p=-\frac{\partial H}{\partial q}. \tag{3}$$

Now, write

$$\dot q_i=\frac{(q_{i+1}-q_i)}{\Delta t}, \tag{4}$$

where

$$q_i=q(t) \tag{5}$$

$$q_{i+1}=q(t+\Delta t). \tag{6}$$

Then the equations of motion become

$$q_{i+1}=q_i+p_i\Delta t \tag{7}$$

$$p_{i+1}=p_i-\Delta t\left(\frac{\partial V}{\partial q_i}\right)_{q=qi} \tag{8}$$

Note that equations (7) and (8) are not AREA-PRESERVING, since

$$\frac{\partial(q_{i+1},\ p_{i+1})}{\partial(q_i,\ p_i)}=\begin{vmatrix}1 & -\Delta t\,\dfrac{\partial^2 V}{\partial q_i^2}\\ \Delta t & 1\end{vmatrix}=1+(\Delta t)^2\frac{\partial^2 V}{\partial q_i^2}\neq 1. \tag{9}$$

However, if we take instead of (7) and (8),

$$q_{i+1}=q_i+p_i\Delta t \tag{10}$$

$$p_{i+1}=p_i-\Delta t\left(\frac{\partial V}{\partial q_i}\right)_{q=q_{i+1}} \tag{11}$$

$$\frac{\partial(q_{i+1},\ p_{i+1})}{\partial(q_i,\ p_i)}=\begin{vmatrix}1 & -\Delta t\,\dfrac{\partial}{\partial q_i}\left(\dfrac{\partial V}{\partial q}\right)_{q=q_{i+1}}\\ \Delta t & 1\end{vmatrix}$$

$$=1+(\Delta t)^2\frac{\partial^2 V}{\partial q_i^2}=1, \tag{12}$$

which is AREA-PRESERVING.

See also AREA-PRESERVING MAP

Hamiltonian Path

A path between two vertices of a GRAPH that visits each vertex exactly once. A Hamiltonian path that is also a GRAPH CYCLE is called a HAMILTONIAN CIRCUIT (or Hamiltonian cycle). Every TOURNAMENT has an ODD NUMBER of Hamiltonian paths (Rédei 1934; Szele 1943; Skiena 1990, p. 175).

The number of Hamiltonian paths on an n-HYPERCUBE is 0, 0, 48, 48384, ... (Sloane's A006070; Gardner 1986, pp. 23–4).

See also HAMILTONIAN CIRCUIT, HAMILTONIAN GRAPH, TOURNAMENT

Hamiltonian System

A system of variables which can be written in the form of HAMILTON'S EQUATIONS.

Hammer's X-Ray Problems

Let a homogeneous solid contain a convex hole K and take x-rays so that the "darkness" at each point on a photographic plate determines the length of the chord of K along the line of propagation of an x-ray. Then

how many x-ray pictures must be taken to exactly reconstruct K if

1. The x-rays originate from a point source,
2. The x-rays originate from a source at infinity and so are parallel?

See also Radon Transform

References

Croft, H. T.; Falconer, K. J.; and Guy, R. K. "Hammer's X-Ray Problems." §A2 in *Unsolved Problems in Geometry.* New York: Springer-Verlag, pp. 11–4, 1991.

Hammer-Aitoff Equal-Area Projection

A map projection whose inverse is defined using the intermediate variable

$$z \equiv \sqrt{1-\left(\tfrac{1}{4}x\right)^2-\left(\tfrac{1}{2}y\right)^2}.$$

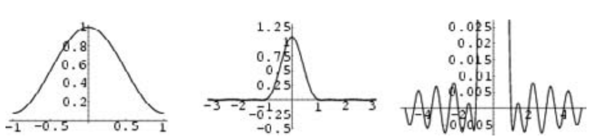
Then the longitude and latitude are given by

$$\lambda = 2\tan^{-1}\left[\frac{zx}{2(2z^2-1)}\right]$$

$$\phi = \sin^{-1}(yz).$$

See also Equal-Area Projection

Hamming Code



A binary Hamming code H_r of length $n=2^r-1$ (with $r \geq 2$) is a linear code with parity-check matrix $\mathbf{H}$ whose columns consist of all nonzero binary vectors of length r, each used once. H_r is an $(n=2^r-1,\ k=2^r-1-r,\ d=3)$ code. Hamming codes are perfect single error-correcting codes.

See also Error-Correcting Code, Perfect Code

References

MacWilliams, F. J. and Sloane, N. J. A. *The Theory of Error-Correcting Codes.* Amsterdam, Netherlands: North-Holland, 1977.

Hamming Function

An apodization function chosen to minimize the height of the highest sidelobe (Hamming and Tukey, Blackman and Tukey 1959). The Hamming function is given by

$$A(x) = 0.54 + 0.46\cos\left(\frac{\pi x}{a}\right), \tag{1}$$

and its full width at half maximum is $1.05543a$. The corresponding instrument function is

$$I(k) = \frac{a(1.08-0.64a^2k^2)\,\mathrm{sinc}(2\pi ak)}{1-4a^2k^2}. \tag{2}$$

This apodization function is close to the one produced by the requirement that the apparatus function goes to 0 at $ka=5/4$. From apodization function, a general symmetric apodization function $A(x)$ can be written as a Fourier series

$$A(x) = a_0 + 2\sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x}{b}\right), \tag{3}$$

where the coefficients satisfy

$$a_0 + 2\sum_{n=1}^{\infty} a_n = 1. \tag{4}$$

The corresponding apparatus function is

$$I(t) = 2b\{a_0\,\mathrm{sinc}(2\pi kb) + \sum_{n=1}^{\infty}[\mathrm{sinc}(2\pi kb+n\pi)+\mathrm{sinc}(2\pi kb-n\pi)]\}. \tag{5}$$

To obtain an apodization function with zero at $ka=3/4$, use

$$a_0 + 2a_1 = 1, \tag{6}$$

so

$$a_0\,\mathrm{sinc}\left(\tfrac{5}{2}\pi\right) + a_1\left[\mathrm{sinc}\left(\tfrac{7}{2}\pi\right)+\mathrm{sinc}\left(\tfrac{3}{2}\pi\right)\right] = 0 \tag{7}$$

$$(1-2a_1)\frac{2}{5\pi} - a_1\left(\frac{2}{7\pi}+\frac{2}{3\pi}\right) = (1-2a_1)\tfrac{1}{5} - a_1\left(\tfrac{1}{7}+\tfrac{1}{3}\right) = 0 \tag{8}$$

$$a_1\left(\tfrac{1}{7}+\tfrac{1}{3}+\tfrac{2}{5}\right) = \tfrac{1}{5} \tag{9}$$

$$a_1 = \frac{\frac{1}{5}}{\frac{2}{5}+\frac{1}{7}+\frac{1}{3}} = \frac{7\cdot 3}{2\cdot 3\cdot 7+3\cdot 5+5\cdot 7} = \tfrac{21}{92} \approx 0.2283 \tag{10}$$

$$a_0 = 1-2a_1 = \frac{92-2\cdot 21}{92} = \frac{92-42}{92} = \tfrac{50}{92} = \tfrac{25}{46} \approx 0.5435. \tag{11}$$

The FWHM is 1.81522, the peak is 1.08, the peak negative and positive sidelobes (in units of the peak) are –0.00689132 and 0.00734934, respectively.

Handle

A handle is a topological structure which can be thought of as the object produced by puncturing a surface twice, attaching a ZIP around each puncture travelling in opposite directions, pulling the edges of the zips together, and then zipping up.

Handles are to MANIFOLDS as CELLS are to CW-COMPLEXES. If M is a MANIFOLD together with a $(k-1)$-SPHERE $\mathbb{S}^{k-1}$ embedded in its boundary with a trivial TUBULAR NEIGHBORHOOD, we attach a k-handle to M by gluing the tubular NEIGHBORHOOD of the $(k-1)$-SPHERE $\mathbb{S}^{k-1}$ to the TUBULAR NEIGHBORHOOD of the standard $(k-1)$-SPHERE $\mathbb{S}^{k-1}$ in the $\dim(M)$-dimensional DISK. In this way, attaching a k-handle is essentially just the process of attaching a fattened-up k-DISK to M along the $(k-1)$-SPHERE $\mathbb{S}^{k-1}$. The embedded DISK in this new MANIFOLD is called the k-handle in the UNION of M and the handle.

DYCK'S THEOREM states that HANDLES and cross-handles are equivalent in the presence of a CROSS-CAP.

POWERFUL NUMBER

Hankel Contour

Hankel contour C_ε

The CONTOUR C_ϵ illustrated above.

See also HANKEL FUNCTION

References

Krantz, S. G. "The Hankel Contour and Hankel Functions." §13.2.4 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, p. 159, 1999.

Hankel Function

There are two types of functions known as Hankel functions. The more common one is a COMPLEX

FUNCTION (also called a Bessel function of the third kind, or Weber Function) which is a LINEAR COMBINATION of BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS. These are called the HANKEL FUNCTIONS OF THE FIRST and SECOND KINDS.

Another type of Hankel function is defined by the CONTOUR INTEGRAL

$$H_\epsilon(z) = \int_{C_\epsilon} \frac{(-w)^{z-1} e^{-w}}{1 - e^{-w}}\, dw$$

for $\Im[w] < 0$, $|\arg(-w)| < \pi$, $\epsilon \neq 2\pi k > 0$, where C_ϵ is a HANKEL CONTOUR. The RIEMANN ZETA FUNCTION can be expressed in terms of $H_\epsilon(z)$ as

$$\zeta(z) = -\frac{H_\epsilon(z)}{2i \sin(\pi z)\Gamma(z)}$$

for $0 < \epsilon < 2\pi$ and $\Re[z] > 1$, where $\Gamma(z)$ is the GAMMA FUNCTION (Krantz 1999, p. 160).

Hankel Function of the First Kind

$$H_n^{(1)}(z) \equiv J_n(z) - iY_n(z),$$

where $J_n(z)$ is a BESSEL FUNCTION OF THE FIRST KIND and $Y_n(z)$ is a BESSEL FUNCTION OF THE SECOND KIND. Hankel functions of the first kind can be REPRESENTED AS a CONTOUR INTEGRAL over the UPPER HALF-PLANE using

$$H_n^{(1)}(z) = \frac{1}{i\pi} \int_{0[\text{upper half plane}]}^{\infty} \frac{e^{(z/2)(t-1/t)}}{t^{n+1}}\, dt.$$

The plots above show the structure of $H_0^{(1)}(z)$ in the COMPLEX PLANE.

Hankel Matrix

A MATRIX H_n where the first row (and column) consists of the integers 1, 2, ..., n, the second row (and column) is given by 2, 3, ..., n, 0, and so on, with the nth row (and column) given by n,

$$\underbrace{0,\ \ldots,\ 0}_{n-1}.$$

A Hankel matrix can be given by `HankelMatrix[m, n]` in the *Mathematica* add-on package `LinearAlgebra'MatrixManipulation'` (which can be loaded with the command `<<LinearAlgebra'`). The first few such matrices are

$$\mathsf{H}_2 = \begin{bmatrix} 1 & 2 \\ 2 & 0 \end{bmatrix}$$

$$\mathsf{H}_3 = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 0 \\ 3 & 0 & 0 \end{bmatrix}$$

$$\mathsf{H}_4 = \begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 3 & 4 & 0 \\ 3 & 4 & 0 & 0 \\ 4 & 0 & 0 & 0 \end{bmatrix}.$$

The elements of the Hankel matrix are given explicitly by

$$h_{ij} = \begin{cases} 0 & \text{if } i+j-1 > n \\ i+j-1 & \text{otherwise.} \end{cases}$$

The DETERMINANT of H_n is given by $\det(H_n) = (-1)^{\lfloor n/2 \rfloor} n^n$, where $\lfloor n \rfloor$ is the FLOOR FUNCTION, so the first few values are 1, -4, -27, 256, 3125, -46656, -823543, 16777216, ... (Sloane's A000312).

Hankel Transform

Equivalent to a 2-D FOURIER TRANSFORM with a radially symmetric KERNEL, and also called the FOURIER-BESSEL TRANSFORM.

$$g(u,\ v) = \mathscr{F}[f(r)] = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(r) e^{-2\pi i(ux+vy)}\, dx\, dy. \quad (1)$$

Let

$$x + iy = re^{i\theta} \quad (2)$$

$$u + iv = qe^{i\phi} \quad (3)$$

so that

$$x = r \cos \theta \quad (4)$$

$$y = r \sin \theta \quad (5)$$

$$r = \sqrt{x^2 + y^2} \quad (6)$$

$$u = q \cos \phi \quad (7)$$

$$v = q \sin \phi \quad (8)$$

$$q = \sqrt{u^2 + v^2}. \quad (9)$$

Then

$$\begin{aligned} g(q) &= \int_0^\infty \int_0^{2\pi} f(r) e^{-2\pi irq(\cos\phi\cos\theta + \sin\phi\sin\theta)} r\, dr\, d\theta \\ &= \int_0^\infty \int_0^{2\pi} f(r) e^{-2\pi irq\cos(\theta-\phi)} r\, dr\, d\theta \\ &= \int_0^\infty \int_{-\phi}^{2\pi-\phi} f(r) e^{-2\pi irq\cos\theta} r\, dr\, d\theta \\ &= \int_0^\infty \int_0^{2\pi} f(r) e^{-2\pi irq\cos\theta} r\, dr\, d\theta \\ &= \int_0^\infty f(r) \left[\int_0^{2\pi} e^{-2\pi irq\cos\theta} d\theta \right] r\, dr \\ &= 2\pi \int_0^\infty f(r) J_0(2\pi qr) r\, dr, \end{aligned} \quad (10)$$

where $J_0(z)$ is a zeroth order BESSEL FUNCTION OF THE FIRST KIND.

Therefore, the Hankel transform pairs are

$$g(q) = 2\pi \int_0^\infty f(x) J_0(2\pi qr) r\, dr \quad (11)$$

$$f(r) = 2\pi \int_0^\infty g(q) J_0(2\pi qr) q\, dq. \quad (12)$$

The following table gives Hankel transforms for a number of common functions (Bracewell 1999, p. 249). Here, $J_n(x)$ is a BESSEL FUNCTION and $\prod_a(r)$ is a RECTANGLE FUNCTION equal to 1 for $0 \le r \le a$ and 0 otherwise, and

$$M(x) = 2\pi\left[x^{-3}\int_0^x J_0(x)\,dx - x^{-2}J_0(x)\right] \quad (13)$$

$$= \frac{\pi^2}{x^2}[J_1(x)\mathscr{H}_0(x) - J_0(x)\mathscr{H}_1(x)], \quad (14)$$

where $J_n(x)$ is a BESSEL FUNCTION OF THE FIRST KIND, $\mathscr{H}_n(x)$ is a STRUVE FUNCTION and $\mathscr{L}_n(x)$ is a MODIFIED STRUVE FUNCTION.

$f(r)$	$g(q)$
$\prod_a(r)$	$\frac{aJ_1(2\pi aq)}{q}$
$\frac{\sin(2\pi ar)}{r}$	$\frac{\prod(q/(2a))}{\sqrt{a^2-q^2}}$
$\frac{1}{2}\delta(r-a)$	$\pi a J_0(2\pi aq)$
$M(ar)$	$a\Lambda\left(\frac{q}{2a}\right)$
$e^{-\pi r^2}$	$e^{-\pi q^2}$
$(a^2+r^2)^{-1/2}$	$\frac{e^{-2\pi aq}}{q}$
$(a^2+r^2)^{-1/3}$	$\frac{2\pi e^{-2\pi aq}}{a}$
$\frac{1}{a^2+r^2}$	$2\pi K_0(2\pi aq)$
$\frac{2a^2}{(a^2+r^2)^2}$	$4\pi^2 aqK_1(2\pi aq)$
$\frac{4a^4}{(a^2+r^2)^3}$	$4\pi^3 a^2q^2K_2(2\pi aq)$
$(a^2-r^2)\prod_a(r)$	$\frac{a^2}{\pi q^2}J_2(2\pi aq)$
$\frac{1}{r}$	$\frac{1}{q}$
e^{-ar}	$\frac{2\pi a}{(a^2+4\pi^2q^2)^{3/2}}$
$\frac{e^{-ar}}{r}$	$\frac{2\pi}{\sqrt{a^2+4\pi^2q^2}}$
$\frac{\delta(r)}{2\pi r}$	1
$r^2e^{-\pi r2}$	$\frac{e^{-\pi q2}(1-\pi q^2)}{\pi}$
$-r^2f(r)$	$\left(\frac{d^2f}{dq^2}+\frac{1}{q}\frac{dF}{dq}\right)=\nabla^2 f$

Hankel's Integral

$$J_m(x) = \frac{x^m}{2^{m-1}\sqrt{\pi}\,\Gamma\left(m+\frac{1}{2}\right)}\int_0^1 \cos(xt)$$
$$\times\left(1-t^2\right)^{m-1/2}dt,$$

where $J_m(x)$ is a BESSEL FUNCTION OF THE FIRST KIND and $\Gamma(z)$ is the GAMMA FUNCTION. Hankel's integral can be derived from SONINE'S INTEGRAL.

See also POISSON INTEGRAL, SONINE'S INTEGRAL

Hankel's Symbol

The symbol defined by

$$(v,\ n)$$
$$\equiv \frac{2^{-2n}\left\{(4v^2-1)(4v^2-3^2)\cdots\left[4v^2-(2n-1)^2\right]\right\}}{n!} \quad (1)$$

$$= \frac{(-1)^n\cos(\pi v)\Gamma\left(\frac{1}{2}+n-v\right)\Gamma\left(\frac{1}{2}+n+v\right)}{xn!}, \quad (2)$$

where $\Gamma(z)$ is the GAMMA FUNCTION. If v is an integer, then this simplifies to

$$(v,\ n) = \frac{(-1)^{n+v}\Gamma\left(\frac{1}{2}+n-v\right)\Gamma\left(\frac{1}{2}+n+v\right)}{\pi n!}, \quad (3)$$

given incorrectly by Erdélyi *et al.* (1981, p. 52).

Hann Function

HANNING FUNCTION

Hanning Function

An APODIZATION FUNCTION, also called the HANN FUNCTION, frequently used to reduce ALIASING in

FOURIER TRANSFORMS. The illustrations above show the Hanning function, its INSTRUMENT FUNCTION, and a blowup of the INSTRUMENT FUNCTION sidelobes. It is named after the Austrian meteorologist Julius von Hann (Blackman and Tukey 1959, pp. 98–9). The Hanning function is given by

$$f(x)=\cos^2\left(\frac{\pi x}{2a}\right)=\tfrac{1}{2}-\tfrac{1}{2}\cos\left(\frac{\pi x}{a}\right). \quad (1)$$

The INSTRUMENT FUNCTION for Hanning apodization can also be written

$$a\left[\operatorname{sinc}(2\pi ka)+\tfrac{1}{2}\operatorname{sinc}(2\pi ka-\pi)+\tfrac{1}{2}\operatorname{sinc}(2\pi ka+\pi)\right]. \quad (2)$$

Its FULL WIDTH AT HALF MAXIMUM is a. It has APPARATUS FUNCTION

$$\begin{aligned}A(x)&=\int_{-a}^{a}\left[\tfrac{1}{2}-\tfrac{1}{2}\cos\left(\frac{\pi x}{a}\right)\right]e^{-2\pi ikx}\,dx\\&=\tfrac{1}{2}\int_{-a}^{a}e^{-2\pi ikx}\,dx-\tfrac{1}{2}\int_{-a}^{a}e^{-2\pi ikx}\,dx\\&\equiv\tfrac{1}{2}(A_1+A_2).\end{aligned} \quad (3)$$

The first integral is

$$I_1=\int_{-a}^{a}e^{-2\pi ikx}\,dx=\frac{\sin(2\pi ka)}{\pi k}=2a\operatorname{sinc}(2\pi ka). \quad (4)$$

The second integral can be rewritten

$$\begin{aligned}I_2&=\int_{-a}^{0}\cos\left(\frac{\pi x}{a}\right)e^{-2\pi ikx}\,dx+\int_{-a}^{0}\cos\left(\frac{\pi x}{a}\right)e^{-2\pi ikx}\,dx\\&=\int_{0}^{a}\cos\left(\frac{\pi x}{a}\right)(e^{2\pi ikx}+e^{-2\pi ikx})\,dx\\&=2\int_0^a\cos\left(\frac{\pi x}{a}\right)\cos(2\pi kx)\,dx\\&=2\left\{\frac{\sin\left(\frac{\pi}{a}-2\pi k\right)x}{2\left(\frac{\pi}{a}-2\pi k\right)}+\frac{\sin\left(\frac{\pi}{a}+2\pi k\right)x}{2\left(\frac{\pi}{a}+2\pi k\right)}\right\}_0^a\\&=a\left[\frac{\sin(\pi-2\pi ka)}{\pi-2\pi ka}+\frac{\sin(\pi+2\pi ka)}{\pi+2\pi ka}\right]\\&=\frac{a}{\pi}\left[\frac{\sin(2\pi ka)}{1-2ka}-\frac{\sin(2\pi ka)}{1+2ka}\right]\\&=a[\operatorname{sinc}(\pi-2\pi ka)+\operatorname{sinc}(\pi+2\pi ka)].\end{aligned} \quad (5)$$

Combining (4) and (5) gives

$$A(x)=a\left[\operatorname{sinc}(2\pi ka)+\tfrac{1}{2}\operatorname{sinc}(\pi-2\pi ka)+\tfrac{1}{2}\operatorname{sinc}(\pi+2\pi ka)\right]. \quad (6)$$

To find the extrema, define $x\equiv 2\pi ka$ and rewrite (6) as

$$A(x)=a\left[\sin x+\tfrac{1}{2}\operatorname{sinc}(x-\pi)+\tfrac{1}{2}\operatorname{sinc}(x+\pi)\right]. \quad (7)$$

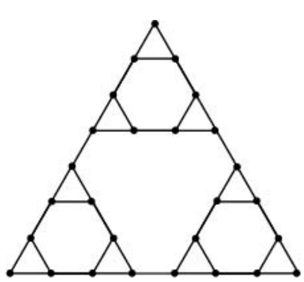
Then solve

$$\frac{dA}{dx}=\frac{\pi^2(-x^3\cos x+3x^2\sin x+\pi^2 x\cos x-\pi^2\sin x)}{x^2(\pi^2-x^2)^2}=0 \quad (8)$$

to find the extrema. The roots are $x=7.42023$ and 10.7061, giving a peak NEGATIVE sidelobe of –0.026708 and a peak POSITIVE sidelobe (in units of a) of 0.00843441. The peak in units of a is 1, and the full-width at half maximum is given by setting (7) equal to 1/2 and solving for x, yielding

$$x_{1/2}=2\pi k_{1/2}a=\pi. \quad (9)$$

Therefore, with $L\equiv 2a$, the FULL WIDTH AT HALF MAXIMUM is



$$\text{FWHM}=2k_{1/2}=\frac{1}{a}=\frac{2}{L}. \quad (10)$$

Happy End Problem

The problem of determining the smallest number of points $g(n)$ in GENERAL POSITION in the plane (i.e., no three of which are COLLINEAR), which always determine a CONVEX POLYGON of n sides. The problem was so-named by Erdos when two investigators who first worked on the problem, E. Klein and G. Szekeres, became engaged and subsequently married (Hoffman 1998, p. 76).

the three cases for 5 points *counterexample for 8 points*

E. Klein proved that $g(4) = 5$ by showing that any arrangement of five points must fall into one of the three cases (left figure), and E. Makai proved $g(5) = 9$ after demonstrating that a counterexample could be found for eight points (right figure; Hoffman 1998, pp. 75–6). Erdos and Szekeres (1935) showed that $g(n)$ exists and derived the bound

$$2^{n-2} + 1 \le g(n) \le \binom{2n-4}{n-2} + 1, \quad (1)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. For $n \ge 4$, this has since been reduced to

$$g(n) \le \binom{2n-4}{n-2} \quad (2)$$

by Chung and Graham (1998),

$$g(n) \le \binom{2n-4}{n-2} + 7 - 2n \quad (3)$$

by Kleitman and Pachter (1998), and

$$g(n) \le \binom{2n-5}{n-2} + 2 \quad (4)$$

by Tóth and Valtr (1998). For $g(6)$, these bounds give 71, 70, 65, and 37, respectively (Hoffman 1998, p. 78). The values of (4) for $n = 6, 7, \ldots$ are 37, 128, 464, 1718, ... (Sloane's A052473).

Happy Number

Let the sum of the SQUARES of the DIGITS of a POSITIVE INTEGER s_0 be represented by s_1. In a similar way, let the sum of the SQUARES of the DIGITS of s_1 be represented by s_2, and so on. If $s_i = 1$ for some $i \geq 1$, then the original INTEGER s_0 is said to be happy.

Once it is known whether a number is happy (or not), then any number in the sequence s_1, s_2, s_3, ... will also be happy (or not). A number which is not happy is called UNHAPPY. Unhappy numbers have EVENTUALLY PERIODIC sequences of s_i which do not reach 1 (e.g., 4, 16, 37, 58, 89, 145, 42, 20, 4, ...).

Any PERMUTATION of the DIGITS of an UNHAPPY or happy number must also be unhappy or happy. This follows from the fact that ADDITION is COMMUTATIVE. The first few happy numbers are 1, 7, 10, 13, 19, 23, 28, 31, 32, 44, 49, 68, 70, 79, 82, 86, 91, 94, 97, 100, ... (Sloane's A007770). These are also the numbers whose 2-RECURRING DIGITAL INVARIANT sequences have period 1.

The first few happy primes are 7, 13, 19, 23, 31, 79, 97, 103, 109, 139, ... (Sloane's A035497).

Hard Hexagon Entropy Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A constant related to the HARD SQUARE ENTROPY CONSTANT. This constant is given by

$$\kappa_h \equiv \lim_{N\to\infty} [G(N)]^{1/N} = 1.395485972\ldots, \tag{1}$$

where $G(N)$ is the number of configurations of nonattacking KINGS on an $n \times n$ CHESSBOARD with regular hexagonal cells, where $N \equiv n^2$. Amazingly, κ_h is algebraic and given by

$$\kappa_h \equiv \kappa_1\kappa_2\kappa_3\kappa_4, \tag{2}$$

where

$$\kappa_1 \equiv 4^{-1}3^{5/4}11^{-5/12}c^{-2} \tag{3}$$

$$\kappa_2 \equiv \left[1-\sqrt{1-c}+\sqrt{2+c+2\sqrt{1+c+c^2}}\right]^2 \tag{4}$$

$$\kappa_3 \equiv \left[-1-\sqrt{1-c}+\sqrt{2+c+2\sqrt{1+c+c^2}}\right]^2 \tag{5}$$

$$\kappa_4 \equiv \left[\sqrt{1-a}+\sqrt{2+a+2\sqrt{1+a+a^2}}\right]^{-1/2} \tag{6}$$

$$a \equiv -\tfrac{124}{363}\,11^{1/3} \tag{7}$$

$$b \equiv \tfrac{2501}{11979}\,33^{1/2} \tag{8}$$

$$c \equiv \left\{\tfrac{1}{4}+\tfrac{3}{8}a\left[(b+1)^{1/3}-(b-1)^{1/3}\right]\right\}^{1/3}. \tag{9}$$

(Baxter 1980, Joyce 1988).

Hard Square Entropy Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $F(m, n)$ be the number of $m \times n$ BINARY MATRICES with no adjacent 1s (in either columns or rows). For $n = 1, 2, \ldots, F(n, n)$ is given by 2, 7, 63, 1234, ... (Sloane's A006506).

The hard square entropy constant is defined by

$$\kappa \equiv \lim_{n\to\infty} [F(n, n)]^{1/n^2} = 1.503048082\ldots.$$

The quantity $\ln \kappa$ arises in statistical physics (Baxter *et al.* 1980, Pearce and Seaton 1988), and is known as the entropy per site of hard squares. A related constant known as the HARD HEXAGON ENTROPY CONSTANT can also be defined.

Hardy Function

RIEMANN-SIEGEL FUNCTIONS

Hardy Space

If $0 < p < \infty$, then the Hardy space $H^p(D)$ is the class of functions holomorphic on the disk D and satisfying the growth condition

$$\|f\|_{H^p} \sup_{0<r<1}\left[\frac{1}{2\pi}\int_0^{2\pi}\left|f\left(re^{i\theta}\right)\right|^p d\theta\right]^{1/p} < \infty,$$

where $\|f\|_{H^p}$ is the Hardy norm.

Hardy Z-Function

Riemann-Siegel Functions

Hardy's Inequality

Let $\{a_n\}$ be a nonnegative sequence and $f(x)$ a nonnegative integrable function. Define

$$A_n = \sum_{k=1}^{n} a_k \tag{1}$$

and

$$F(x) = \int_0^x f(t)\,dt \tag{2}$$

and take $p > 1$. For sums,

$$\sum_{n=1}^{\infty} \left(\frac{A_n}{n}\right)^p < \left(\frac{p}{p-1}\right)^p \sum_{n=1}^{\infty} (a_n)^p \tag{3}$$

(unless all $a_n = 0$), and for integrals,

$$\int_0^{\infty} \left[\frac{F(x)}{x}\right]^p dx < \left(\frac{p}{p-1}\right)^p \int_0^{\infty} [f(x)]^p\,dx \tag{4}$$

(unless f is identically 0).

Hardy's Rule

Let the values of a function $f(x)$ be tabulated at points x_i equally spaced by $h = x_{i+1} - x_i$, so $f_1 = f(x_1)$, $f_2 = f(x_2)$, ..., $f_7 = f(x_7)$. Then Hardy's rule approximating the integral of $f(x)$ is given by the Newton-Cotes-like formula

$$\int_{x_1}^{x_7} f(x)\,dx = \tfrac{1}{100} h(28f_1 + 162f_2 + 220f_4 + 162f_6 + 28f_7).$$

Hardy-Littlewood Conjectures

The first Hardy-Littlewood conjecture is called the k-tuple conjecture. It states that the asymptotic number of prime constellations can be computed explicitly.

The second Hardy-Littlewood conjecture states that

$$\pi(x+y) - \pi(x) \leq \pi(y)$$

for all x and y, where $\pi(x)$ is the prime counting function. Although it is not obvious, Richards (1974) proved that this conjecture is incompatible with the first Hardy-Littlewood conjecture.

Prime Patterns Conjecture

Hardy-Littlewood Tauberian Theorem

Let $a_n \geq 0$ and suppose

$$\sum_{n=1}^{\infty} a_n e^{-an} \sim \frac{1}{a}$$

as $a \to 0^+$. Then

$$\sum_{n \leq x} a_n \sim x$$

as $x \to \infty$. This theorem is a step in the proof of the PRIME NUMBER THEOREM, but has subsequently been superseded by an approach due to Wiener (Hardy 1999, p. 34).

Hardy-Ramanujan Number

The smallest nontrivial TAXICAB NUMBER, i.e., the smallest number representable in two ways as a sum of two CUBES. It is given by

$$1729 = 1^3 + 12^3 = 9^3 + 10^3.$$

The number derives its name from the following story G. H. Hardy told about Ramanujan. "Once, in the taxi from London, Hardy noticed its number, 1729. He must have thought about it a little because he entered the room where Ramanujan lay in bed and, with scarcely a hello, blurted out his disappointment with it. It was, he declared, 'rather a dull number,' adding that he hoped that wasn't a bad omen. 'No, Hardy,' said Ramanujan, 'it is a very interesting number. It is the smallest number expressible as the sum of two [POSITIVE] cubes in two different ways'" (Hofstadter 1989, Kanigel 1991, Snow 1993; Hardy 1999, pp. 13 and 68).

Hardy-Ramanujan Theorem

Let $\omega(n)$ be the number of DISTINCT PRIME FACTORS of n. If $\Psi(x)$ tends steadily to infinity with x, then

$$\ln \ln x - \Psi(x)\sqrt{\ln \ln x} < \omega(n) < \ln \ln x + \Psi(x)\sqrt{\ln \ln x}$$

for ALMOST ALL numbers $n < x$. "ALMOST ALL" means here the frequency of those INTEGERS n in the interval $1 \leq n \leq x$ for which

$$|\omega(n) - \ln \ln x| > \Psi(x)\sqrt{\ln \ln x}$$

approaches 0 as $x \to \infty$.

See also DISTINCT PRIME FACTORS, ERDOS-KAC THEOREM

Harmonic

The word "harmonic" has several distinct meanings in mathematics, none of which is obviously related to the others. SIMPLE HARMONIC MOTION or "harmonic oscillation" refers to oscillations with a sinusoidal waveform. Such functions satisfy the differential equation

$$\frac{d^2x}{dt^2} + \omega^2 x = 0, \tag{1}$$

which has solution

$$x = A\cos(\omega t + \phi_1) + B\sin(\omega t + \phi_2). \tag{2}$$

The word HARMONIC ANALYSIS is therefore used to describe FOURIER ANALYSIS, which breaks an arbitrary function into a superposition of sinusoids.

In complex analysis, a HARMONIC FUNCTION refers to a real-valued function $f(x, y)$ which satisfies LAPLACE'S EQUATION

$$\nabla^2 f(x, y) = 0, \tag{3}$$

where ∇^2 is the LAPLACIAN. Although this definition is similar to that of harmonic oscillation, it omits the second term in the differential equation. The HELMHOLTZ DIFFERENTIAL EQUATION is obtained if it is added back in,

$$\nabla^2 f(x, y) + k^2 f(x, y) = 0. \tag{4}$$

For distances along a line segment, a HARMONIC RANGE is a set of four COLLINEAR points A, B, C, and D arranged such that

$$AB : BC = 2 : 1 \tag{5}$$

$$AD : DC = 6 : 3. \tag{6}$$

This use of the term probably arises from the use of "harmonics" to refer to ratios of notes in small integers producing an attractive sound, known in music theory as "harmony."

For a set of data points x_i, the HARMONIC MEAN is defined by

$$\frac{1}{H} \equiv \frac{1}{n} \sum_{i=1}^{n} \frac{1}{x_i}. \tag{7}$$

The connection of this use of "harmonic" with the preceding ones is not obvious.

See also HARMONIC FORM, HARMONIC FUNCTION, HARMONIC RANGE, SIMPLE HARMONIC MOTION

Harmonic Addition Theorem

To convert an equation OF THE FORM

$$f(\theta) = a \cos\theta + b \sin\theta \tag{1}$$

to the form

$$f(\theta) = c \cos(\theta + \delta), \tag{2}$$

expand (2) using the trigonometric addition formulas to obtain

$$f(\theta) = c \cos\theta \cos\delta - c \sin\theta \sin\delta. \tag{3}$$

Now equate the COEFFICIENTS of (1) and (3)

$$a = c \cos\delta \tag{4}$$

$$b = -c \sin\delta, \tag{5}$$

so

$$\tan\delta = -\frac{b}{a} \tag{6}$$

$$a^2 + b^2 = c^2, \tag{7}$$

and we have

$$\delta = \tan^{-1}\left(-\frac{b}{a}\right) \tag{8}$$

$$c = \sqrt{a^2 + b^2}. \tag{9}$$

Given two general sinusoidal functions with frequency ω:

$$\psi_1 = A_1 \sin(\omega t + \delta_1) \tag{10}$$

$$\psi_2 = A_2 \sin(\omega t + \delta_2), \tag{11}$$

their sum ψ can be expressed as a sinusoidal function with frequency ω

$$\begin{aligned}\psi &\equiv \psi_1 + \psi_2 \\ &= A_1[\sin(\omega t)\cos\delta_1 + \sin\delta_1 \cos(\omega t)] \\ &\quad + A_2[\sin(\omega t)\cos\delta_2 + \sin\delta_2 \cos(\omega t)] \\ &= [A_1 \cos\delta_1 + A_2 \cos\delta_2] \sin(\omega t) \\ &\quad + [A_1 \sin\delta_1 + A_2 \sin\delta_2] \cos(\omega t).\end{aligned} \tag{12}$$

Now, define

$$A \cos\delta \equiv A_1 \cos\delta_1 + A_2 \cos\delta_2 \tag{13}$$

$$A \sin\delta \equiv A_1 \sin\delta_1 + A_2 \sin\delta_2. \tag{14}$$

Then (12) becomes

$$A \cos\delta \sin(\omega t) + A \sin\delta \cos(\omega t) = A \sin(\omega t + \delta). \tag{15}$$

Square and add (13) and (14)

$$A_2 = A_1^2 + A_2^2 + 2A_1A_2 \cos(\delta_2 - \delta_1). \tag{16}$$

Also, divide (14) by (13)

$$\tan\delta = \frac{A_1 \sin\delta_1 + A_2 \sin\delta_2}{A_1 \cos\delta_1 + A_2 \cos\delta_2}, \tag{17}$$

so

$$\psi = A \sin(\omega t + \delta), \tag{18}$$

where A and δ are defined by (16) and (17).

This procedure can be generalized to a sum of n harmonic waves, giving

$$\psi = \sum_{i=1}^{n} A_i \cos(\omega t + \delta_i) = A \cos(\omega t + \delta), \tag{19}$$

where

$$A^2 \equiv \sum_{i=1}^{n} \sum_{j=1}^{n} A_i A_j \cos(\delta_i - \delta_j) \tag{20}$$

$$= \sum_{i=1}^{n} A_i^2 + 2 \sum_{i=1}^{n} \sum_{j>1}^{n} A_i A_j \cos(\delta_i - \delta_j) \tag{21}$$

and

$$\tan\delta = \frac{\sum_{i=1}^{n} A_i \sin\delta_i}{\sum_{i=1}^{n} A_i \cos\delta_i}. \tag{22}$$

Harmonic Analysis

FOURIER SERIES

Harmonic Brick

A right-angled PARALLELEPIPED with dimensions $a \times ab \times abc$, where a, b, and c are INTEGERS.

See also BRICK, DE BRUIJN'S THEOREM, EULER BRICK

Harmonic Conjugate Function

The harmonic conjugate to a given function $u(x, y)$ is a function $v(x, y)$ such that

$$f(x, y) = u(x, y) + iv(x, y)$$

is COMPLEX DIFFERENTIABLE (i.e., satisfies the CAUCHY-RIEMANN EQUATIONS). It is given by

$$v(z) = \int_{z_0}^{z} u_x\, dy - u_y\, dx + C,$$

where $u_x \equiv \partial u/\partial x$, $u_y \equiv \partial u/\partial y$, and C is a CONSTANT OF INTEGRATION.

Note that $u_x\, dy - u_y\, dx$ is a CLOSED FORM since u is HARMONIC, $u_{xx} + v_{yy} = 0$. The LINE INTEGRAL is WELL DEFINED on a SIMPLY CONNECTED domain because it is closed. However, on a domain which is not simply connected (such as the punctured disk), the harmonic conjugate may not exist.

See also CAUCHY-RIEMANN EQUATIONS, COMPLEX DIFFERENTIABLE, HARDY SPACE, HARMONIC FUNCTION, HILBERT TRANSFORM, SIMPLY CONNECTED

References

Rudin, W. *Real and Complex Analysis.* New York: McGraw-Hill, pp. 350–52, 1987.

Harmonic Conjugate Points

Given COLLINEAR points W, X, Y, and Z, Y and Z are harmonic conjugates with respect to W and X if

$$\frac{|WY|}{|YX|} = \frac{|WZ|}{|XZ|}.$$

The distances between such points are said to be in HARMONIC RATIO, and the LINE SEGMENT depicted above is called a HARMONIC SEGMENT. Harmonic points divide a LINE SEGMENT internally and externally in the same ratio. If $|WZ|=1$, then

$$|WY| = \frac{a(1-a)}{1+a}$$

$$|WX| = \frac{2a}{a+1}.$$

Harmonic conjugate points are also defined for a TRIANGLE. If W and X have TRILINEAR COORDINATES $\alpha : \beta : \gamma$ and $\alpha' : \beta' : \gamma'$, then the TRILINEAR COORDINATES of the harmonic conjugates are

$$Y = \alpha + \alpha' : \beta + \beta' : \gamma + \gamma'$$

$$Z = \alpha - \alpha' : \beta - \beta' : \gamma - \gamma'$$

(Kimberling 1994).

Harmonic Coordinates

Harmonic coordinates satisfy the condition

$$\Gamma^\lambda \equiv g^{\mu\nu}\Gamma^\lambda_{\mu\nu} = 0, \tag{1}$$

or equivalently,

$$\frac{\partial}{\partial x^\kappa}\left(\sqrt{g}g^{\lambda\kappa}\right) = 0. \tag{2}$$

It is always possible to choose such a system. Using the D'ALEMBERTIAN,

$$\Box^2\phi \equiv \left(g^{\lambda\kappa}\phi_{;\lambda}\right)_{;\kappa} = g^{\lambda\kappa}\frac{\partial^2\phi}{\partial x^\lambda \partial x^\kappa} - \Gamma^\lambda \frac{\partial\phi}{\partial x^\lambda}. \tag{3}$$

But since $\Gamma^\lambda \equiv 0$ for harmonic coordinates, the result is a generalization of the harmonic equation

$$\nabla^2 \mathbf{x} = 0 \tag{4}$$

to

$$\Box^2 x^\mu = 0. \tag{5}$$

See also D'ALEMBERTIAN

References

Weinberg, S. *Gravitation and Cosmology: Principles and Applications of the General Theory of Relativity.* New York: Wiley, 1972.

Harmonic Decomposition

A polynomial function of the elements of a VECTOR $\mathbf{x}$ can be uniquely decomposed into a sum of HARMONIC POLYNOMIALS times POWERS of $|\mathbf{x}|$.

See also HARMONIC FUNCTION

Harmonic Divisor Number

A number n for which the HARMONIC MEAN of the DIVISORS of n, i.e., $nd(n)/\sigma(n)$, is an INTEGER, where $d(n)$ is the number of POSITIVE integral DIVISORS of n and $\sigma(n)$ is the DIVISOR FUNCTION. For example, the

divisors of $n = 140$ are 1, 2, 4, 5, 7, 10, 14, 20, 28, 35, 70, and 140, giving

$$d(140) = 12$$

$$\sigma(140) = 336$$

$$\frac{140 d(140)}{\sigma(140)} = \frac{140 \cdot 12}{336} = 5,$$

so 140 is a harmonic divisor number. Harmonic divisor numbers are also called ORE NUMBERS. Garcia (1954) gives the 45 harmonic divisor numbers less than 10^7. The first few are 1, 6, 140, 270, 672, 1638, ... (Sloane's A007340).

For distinct PRIMES p and q, harmonic divisor numbers are equivalent to EVEN PERFECT NUMBERS for numbers OF THE FORM $p^r q$. Mills (1972) proved that if there exists an ODD POSITIVE harmonic divisor number n, then n has a prime-POWER factor greater than 10^7.

Another type of number called "harmonic" is the HARMONIC NUMBER.

Harmonic Equation

LAPLACE'S EQUATION

Harmonic Function

Any REAL FUNCTION $u(x, y)$ with continuous second PARTIAL DERIVATIVES which satisfies LAPLACE'S EQUATION,

$$\nabla^2 u(x, y) = 0, \tag{1}$$

is called a harmonic function. Harmonic functions are called POTENTIAL FUNCTIONS in physics and engineering. Potential functions are extremely useful, for example, in electromagnetism, where they reduce the study of a 3-component VECTOR FIELD to a 1-component SCALAR FUNCTION. A scalar harmonic function is called a SCALAR POTENTIAL, and a vector harmonic function is called a VECTOR POTENTIAL.

To find a class of such functions in the PLANE, write the LAPLACE'S EQUATION in POLAR COORDINATES

$$u_{rr} + \frac{1}{r} u_r + \frac{1}{r^2} u_{\theta\theta} = 0, \tag{2}$$

and consider only radial solutions

$$u_{rr} + \frac{1}{r} u_r = 0. \tag{3}$$

This is integrable by quadrature, so define $v \equiv du/dr$,

$$\frac{dv}{dr} + \frac{1}{r} v = 0 \tag{4}$$

$$\frac{dv}{v} = -\frac{dr}{r} \tag{5}$$

$$\ln\left(\frac{v}{A}\right) = -\ln r \tag{6}$$

$$\frac{v}{A} = \frac{1}{r} \tag{7}$$

$$v = \frac{du}{dr} = \frac{A}{r} \tag{8}$$

$$du = A \frac{dr}{r}, \tag{9}$$

so the solution is

$$u = A \ln r. \tag{10}$$

Ignoring the trivial additive and multiplicative constants, the general pure radial solution then becomes

$$\begin{aligned} u &= \ln\left[(x-a)^2 + (y-b)^2\right]^{1/2} \\ &= \tfrac{1}{2} \ln\left[(x-a)^2 + (y-b)^2\right]. \end{aligned} \tag{11}$$

Other solutions may be obtained by differentiation, such as

$$u = \frac{x-a}{(x-a)^2 + (y-b)^2} \tag{12}$$

$$v = \frac{y-b}{(x-a)^2 + (y-b)^2}, \tag{13}$$

$$u = e^x \sin y \tag{14}$$

$$v = e^x \cos y, \tag{15}$$

and

$$\tan^{-1}\left(\frac{y-b}{x-a}\right). \qquad (16)$$

Harmonic functions containing azimuthal dependence include

$$u = r^n \cos(n\theta) \qquad (17)$$

$$v = r^n \sin(n\theta). \qquad (18)$$

The POISSON KERNEL

$$u(r, R, \theta, \phi) = \frac{R^2 - r^2}{R^2 - 2rR\cos(\theta - \phi) + r^2} \qquad (19)$$

is another harmonic function.

Harmonic Homology

A PERSPECTIVE COLLINEATION with center O and axis o not incident is called a HOMOLOGY. A HOMOLOGY is said to be harmonic if the points A and A' on a line through O are harmonic conjugates with respect to O and $o \cdot a$. Every PERSPECTIVE COLLINEATION of period two is a harmonic homology.

Harmonic Logarithm

For all INTEGERS n and NONNEGATIVE INTEGERS t, the harmonic logarithms $\lambda_n^{(t)}(x)$ of order t and degree n are defined as the unique functions satisfying

1. $\lambda_n^{(t)}(x) = (\ln x)^t$,
2. $\lambda_n^{(t)}(x)$ has no constant term except $\lambda_0^{(0)}(x) = 1$,
3. $\frac{d}{dx}\lambda_n^{(t)}(x) = \lfloor n \rceil \lambda_{n-1}^{(t)}(x)$,

where the "ROMAN SYMBOL" $\lfloor n \rceil$ is defined by

$$\lfloor n \rceil \equiv \begin{cases} n & \text{for } n \neq 0 \\ 1 & \text{for } n = 0 \end{cases} \qquad (1)$$

(Roman 1992). This gives the special cases

$$\lambda_n^{(0)}(x) = \begin{cases} x^n & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \qquad (2)$$

$$\lambda_n^{(1)}(x) = \begin{cases} x^n(\ln x - H_n) & \text{for } n \geq 0 \\ x^n & \text{for } n < 0, \end{cases} \qquad (3)$$

where H_n is a HARMONIC NUMBER

$$H_n \equiv \sum_{k=1}^{n} \frac{1}{k}. \qquad (4)$$

The harmonic logarithm has the INTEGRAL

$$\int \lambda_n^{(1)}(x)\, dx = \frac{1}{\lfloor n+1 \rceil} \lambda_{n+1}^{(1)}(x). \qquad (5)$$

The harmonic logarithm can be written

$$\lambda_n^{(t)}(x) = \lfloor n \rceil ! \tilde{D}^{-n} (\ln x)^t, \qquad (6)$$

where $\tilde{D}$ is the DIFFERENTIAL OPERATOR, (so $\tilde{D}^{-n}$ is the nth INTEGRAL). Rearranging gives

$$\tilde{D}^k \lambda_n^{(t)}(x) = \left\lfloor \frac{\lfloor n \rceil !}{\lfloor n-k \rceil} \right\rceil ! \lambda_{n-k}^{(t)}(x). \qquad (7)$$

This formulation gives an analog of the BINOMIAL THEOREM called the LOGARITHMIC BINOMIAL FORMULA. Another expression for the harmonic logarithm is

$$\lambda_n^{(t)}(x) = x^n \sum_{j=0}^{t} (-1)^j (t)_j c_n^{(j)} (\ln x)^{t-j}, \qquad (8)$$

where $(t)_j = t(t-1)\cdots(t-j+1)$ is a POCHHAMMER SYMBOL and $c_n^{(j)}$ is a two-index HARMONIC NUMBER (Roman 1992).

Harmonic Map

A map $u: M \to N$, between two COMPACT RIEMANNIAN MANIFOLDS, is a harmonic map if it is a critical point for the energy functional

$$\int_M |du|^2 \, d\mu_M.$$

The norm of the differential $|du|$ is given by the metric on M and N and $d\mu_M$ is the measure on M. Typically, the class of allowable maps lie in a fixed HOMOTOPY CLASS of maps.

The EULER-LAGRANGE DIFFERENTIAL EQUATION for the energy functional is a non-linear ELLIPTIC PARTIAL DIFFERENTIAL EQUATION. For example, when M is the circle, then the Euler-Lagrange equation is the same as the geodesic equation. Hence, u is a closed geodesic iff u is harmonic. The map from the circle to the equator of the standard 2-sphere is a harmonic map, and so are the maps that take the circle and map it around the equator n times, for any integer n. Note that these all lie in the same HOMOTOPY CLASS. A higher dimensional example is a MEROMORPHIC FUNCTION on a compact RIEMANN SURFACE, which is a harmonic map to the RIEMANN SPHERE.

A harmonic map may not always exist in a HOMOTOPY CLASS, and if it does it may not be unique. When N is negatively curved, a harmonic representative exists for each HOMOTOPY CLASS, and is also unique. For surfaces, the harmonic maps have been classified, and are precisely the holomorphic maps and the anti-holomorphic maps. Thus by HODGE'S THEOREM for surfaces, there are no non-trivial harmonic maps from the SPHERE to the TORUS.

A harmonic map between RIEMANNIAN MANIFOLDS can be viewed as a generalization of a GEODESIC when the domain DIMENSION is one, or of a HARMONIC FUNCTION when the range is a EUCLIDEAN SPACE.

Harmonic Mean

The harmonic mean $H(x_1, \ldots, x_n)$ of n points x_i (where $i = 1, \ldots, n$) is

$$\frac{1}{H} \equiv \frac{1}{n} \sum_{i=1}^{n} \frac{1}{x_i}. \tag{1}$$

The special cases of $n = 2$ and $n = 3$ are therefore given by

$$H(x_1, x_2) = \frac{2x_1x_2}{x_1 + x_2} \tag{2}$$

$$H(x_1, x_2, x_3) = \frac{3x_1x_2x_3}{x_1x_2 + x_1x_3 + x_2x_3}, \tag{3}$$

and so on.

The VOLUME-to-SURFACE AREA ratio for a cylindrical container with height h and radius r and the MEAN CURVATURE of a general surface are related to the harmonic mean.

Hoehn and Niven (1985) show that

$$H(a_1 + c, a_2 + c, \ldots, a_n + c) > c + H(a_1, a_2, \ldots, a_n) \tag{4}$$

for any POSITIVE constant c.

Harmonic Number

A number OF THE FORM

$$H_n = \sum_{k=1}^{n} \frac{1}{k}. \tag{1}$$

This can be expressed analytically as

$$H_n = \gamma + \psi_0(n+1), \tag{2}$$

where γ is the EULER-MASCHERONI CONSTANT and $\Psi(x)=\psi_0(x)$ is the DIGAMMA FUNCTION. The number formed by taking alternate signs in the sum also has an analytic solution

$$H'_n=\sum_{k=1}^{n}\frac{(-1)^{k+1}}{k} \tag{3}$$

$$=\ln 2+\tfrac{1}{2}(-1)^n\left[\psi_0\left(\tfrac{1}{2}n+\tfrac{1}{2}\right)-\psi_0\left(\tfrac{1}{2}n+1\right)\right]. \tag{4}$$

The first few harmonic numbers H_n are 1, 3/2, 11/6, 25/12, 137/60, ... (Sloane's A001008 and A002805). The harmonic numbers are implemented in *Mathematica* 4.0 as `HarmonicNumber[`*n*`]`.

The harmonic number H_n is never an INTEGER except for H_1, which can be proved by using the strong triangle inequality to show that the 2-ADIC VALUE of H_n is greater than 1 for $n>1$. This result was proved in 1915 by Taeisinger, and the more general results that any number of consecutive terms not necessarily starting with 1 never sum to an integer was proved by Kürschák in 1918 (Hoffman 1998, p. 157).

The harmonic numbers have ODD NUMERATORS and EVEN DENOMINATORS. The nth harmonic number is given asymptotically by

$$H_n\sim\ln n+\gamma+\frac{1}{2n}, \tag{5}$$

where γ is the EULER-MASCHERONI CONSTANT (Conway and Guy 1996). Gosper gave the interesting identity

$$\sum_{i=0}^{\infty}\frac{z^iH_i}{i!}=-e^z\sum_{k=1}^{\infty}\frac{(-z)^k}{kk!}=e^z[\ln z+\Gamma(0,z)+\gamma], \tag{6}$$

where $\Gamma(0,z)$ is the incomplete GAMMA FUNCTION and γ is the EULER-MASCHERONI CONSTANT. Borwein and Borwein (1995) show that

$$\sum_{n=1}^{\infty}\frac{H_n^2}{(n+1)^2}=\tfrac{11}{4}\zeta(4)=\tfrac{11}{360}\pi^4 \tag{7}$$

$$\sum_{n=1}^{\infty}\frac{H_n^2}{n^2}=\tfrac{17}{4}\zeta(4)=\tfrac{17}{360}\pi^4 \tag{8}$$

$$\sum_{n=1}^{\infty}\frac{H_n}{n^3}=\tfrac{5}{4}\zeta(4)=\tfrac{1}{72}\pi^4, \tag{9}$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION. The first of these had been previously derived by de Doelder (1991), and the last by Euler (1775). These identities are corollaries of the identity

$$\frac{1}{\pi}\int_0^{\pi}x^2\left\{\ln\left[2\cos\left(\tfrac{1}{2}x\right)\right]\right\}^2dx=\tfrac{11}{2}\zeta(4)=\tfrac{11}{180}\pi^4 \tag{10}$$

(Borwein and Borwein 1995). Additional identities due to Euler are

$$\sum_{n=1}^{\infty}\frac{H_n}{n^2}=2\zeta(3) \tag{11}$$

$$2\sum_{n=1}^{\infty}\frac{H_n}{n^m}=(m+2)\zeta(m+1)-\sum_{n=1}^{m-2}\zeta(m-n)\zeta(n+1) \tag{12}$$

for $m=2$, 3, ... (Borwein and Borwein 1995), where $\zeta(3)$ is APÉRY'S CONSTANT. These sums are related to so-called EULER SUMS.

There is an unexpected connection between the harmonic numbers and the RIEMANN HYPOTHESIS.

Harmonic numbers of order r can be defined by the relationship

$$H_n^{(r)}=\sum_{k=1}^{n}\frac{1}{k^r}. \tag{13}$$

These number are built into *Mathematica* 4.0 as `HarmonicNumber [`*n*`, `*r*`]`. These numbers obey the unexpected identity

$$9H_8^{(n)}-19H_9^{(n)}+10H_{10}^{(n)}+\sum_{k=1}^{n-1}[H_8^{(n-k)}H_9^{(k)}-H_9^{(n-k)}H_9^{(k)}-H_8^{(n-k)}H_{10}^{(k)}+H_9^{(n-k)}H_{10}^{(k)}]=0 \tag{14}$$

(M. Trott).

Conway and Guy (1996) define the second harmonic number by

$$H_n^2\equiv\sum_{i=1}^{n}H_i=(n+1)(H_{n+1}-1)=(n+1)(H_{n+1}-H_1), \tag{15}$$

the third harmonic number by

$$H_n^3\equiv\sum_{i=1}^{n}H_i^{(2)}=\binom{n+2}{2}(H_{n+2}-H_2), \tag{16}$$

and the nth harmonic number by

$$H_n^k=\binom{n+k-1}{k-1}(H_{n+k-1}-H_{k-1}). \tag{17}$$

A slightly different definition of a two-index harmonic number $c_n^{(j)}$ is given by Roman (1992) in connection with the HARMONIC LOGARITHM. Roman (1992) defines this by

$$c_n^{(0)}=\begin{cases}1 & \text{for } n\geq 0\\ 0 & \text{for } n<0\end{cases} \tag{18}$$

$$c_0^{(j)}=\begin{cases}1 & \text{for } j=0\\ 0 & \text{for } j\neq 0\end{cases} \tag{19}$$

plus the RECURRENCE RELATION

$$cn_n^{(j)} = c_n^{(j-1)} + nc_{n-1}^{(j)}. \quad (20)$$

For general $n > 0$ and $j > 0$, this is equivalent to

$$c_n^{(j)} = \sum_{i=1}^{n} \frac{1}{i} c_i^{(j-1)}, \quad (21)$$

and for $n > 0$, it simplifies to

$$c_n^{(j)} = \sum_{i=1}^{n} \binom{n}{i} (-1)^{i-1} i^{-j}. \quad (22)$$

For $n < 0$, the harmonic number can be written

$$c_n^{(j)} = (-1)^j \lfloor n \rceil ! s(-n, j), \quad (23)$$

where $\lfloor n \rceil !$ is the ROMAN FACTORIAL and s is a STIRLING NUMBER OF THE FIRST KIND.

A separate type of number sometimes also called a "harmonic number" is a HARMONIC DIVISOR NUMBER (or ORE NUMBER).

Harmonic Ratio

HARMONIC RANGE

Harmonic Segment

HARMONIC CONJUGATE POINTS

Harmonic Series

The SUM

$$\sum_{k=1}^{\infty} \frac{1}{k} \quad (1)$$

is called the harmonic series. It can be shown to DIVERGE using the INTEGRAL TEST by comparison with the function $1/x$. The divergence, however, is very slow. The generalization of the harmonic series

$$\zeta(n) \equiv \sum_{k=1}^{\infty} \frac{1}{k^n} \quad (2)$$

is known as the RIEMANN ZETA FUNCTION.

The sum

$$\sum_{k=1}^{\infty} \frac{1}{p_k} \quad (3)$$

taken over all PRIMES p_k also diverges (Wells 1986, p. 41) with asymptotic behavior

$$\sum_{k=1}^{x} \frac{1}{p_k} \sim \ln \ln x + \mathcal{O}(1) \tag{4}$$

(Hardy 1999, p. 50).

Rather surprisingly, the ALTERNATING SERIES

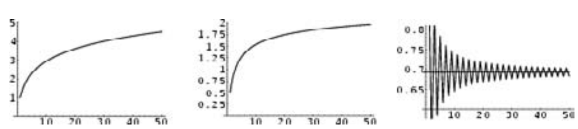
$$\sum_{k=1}^{\infty} \frac{(-1)^{k-1}}{k} = \ln 2 \tag{5}$$

converges to the natural logarithm of 2. An explicit formula for the partial sum of the alternating series is given by

$$\sum_{k=1}^{n} \frac{(-1)^{k-1}}{k} = \ln 2 + \tfrac{1}{2}(-1)^n \left[\psi_0\left(\tfrac{1}{2} + \tfrac{1}{2}n\right) - \psi_0\left(1 + \tfrac{1}{2}n\right)\right]. \tag{6}$$

Gardner (1984) notes that this series never reaches an integral sum.

The sum of the first few terms of the harmonic series is given analytically by the nth HARMONIC NUMBER



$$H_n = \sum_{j=1}^{n} \frac{1}{j} = \gamma + \psi_0(n+1), \tag{7}$$

where γ is the EULER-MASCHERONI CONSTANT and $\Psi(x) = \psi_0(x)$ is the DIGAMMA FUNCTION. The number of terms needed to exceed 1, 2, 3, ... are 1, 4, 11, 31, 83, 227, 616, 1674, 4550, 12367, 33617, 91380, 248397, ... (Sloane's A004080). Using the analytic form shows that after 2.5×10^8 terms, the sum is still less than 20. Furthermore, to achieve a sum greater than 100, more than 1.509×10^{43} terms are needed! Written explicitly, the number of terms is 15,092,688,622,113,788,323,693,563,264,538,101,449, 859,497 (Gardner 1984, p. 167).

Progressions OF THE FORM

$$\frac{1}{a_1}, \frac{1}{a_1 + d}, \frac{1}{a_1 + 2d}, \ldots \tag{8}$$

are also sometimes called harmonic series (Beyer 1987).

The partial sums of the harmonic series are plotted in the left figure above, together with two related series.

Harnack's Theorems

Let s_i be the orders of singular points on a curve (Coolidge 1959, p. 56). Harnack's first theorem states that a real irreducible curve of order n cannot have more than

$$\tfrac{1}{2}(n-1)(n-2) - \sum s_i(s_i - 1) + 1$$

circuits (Coolidge 1959, p. 57).

Harnack's second theorem states that there exists a curve of every order with the maximum number of circuits compatible with that order and with a certain number of double points, provided that number is not permissible for a curve of lower order (Coolidge 1959, p. 61).

Harshad Number

A POSITIVE INTEGER which is DIVISIBLE by the sum of its DIGITS, also called a Niven number (Kennedy *et al.* 1980) or a multidigital number (Kaprekar 1955). The first few are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 18, 20, 21, 24, ... (Sloane's A005349). Grundman (1994) proved that there is no sequence of more than 20 consecutive Harshad numbers, and found the smallest sequence of 20 consecutive Harshad numbers, each member of which has 44,363,342,786 digits.

Grundman (1994) defined an n-Harshad (or n-Niven) number to be a POSITIVE INTEGER which is DIVISIBLE by the sum of its digits in base $n \geq 2$. Cai (1996) showed that for $n = 2$ or 3, there exists an infinite family of sequences of consecutive n-Harshad numbers of length $2n$.

Define an all-Harshad (or all-Niven) number as a positive integer which is divisible by the sum of its

digits in *all* bases $n \geq 2$. Then only 1, 2, 4, and 6 are all-Harshad numbers (A. Kertesz).

Hart Circle

The CIRCLE H which touches the INCIRCLES I, I_A, I_B, and I_C of a CIRCULAR TRIANGLE ABC and its ASSOCIATED TRIANGLES. It is either externally tangent to I and internally tangent to incircles of the ASSOCIATED TRIANGLES I_A, I_B, and I_C (as in the above figure), or vice versa. The Hart circle has several properties which are analogous to the properties on the NINE-POINT CIRCLE of a linear triangle. There are eight Hart circles associated with a given CIRCULAR TRIANGLE.

The Hart circle of any CIRCULAR TRIANGLE and the Hart circles of the three ASSOCIATED TRIANGLES have a common tangent circle which touches the former in the opposite sense to that which it touches the latter (Lachlan 1893, p. 254). In addition, the CIRCUMCIRCLE of any CIRCULAR TRIANGLE is the Hart circle of the CIRCULAR TRIANGLE formed by the circumcircles of the inverse associated triangles (Lachlan 1893, p. 254).

Hartley Transform

An INTEGRAL TRANSFORM which shares some features with the FOURIER TRANSFORM, but which (in the discrete case), multiplies the KERNEL by

$$\cos\left(\frac{2\pi kn}{N}\right)-\sin\left(\frac{2\pi kn}{N}\right) \tag{1}$$

instead of

$$e-2^{\pi ikn/N}=\cos\left(\frac{2\pi kn}{N}\right)-i\sin\left(\frac{2\pi kn}{N}\right). \tag{2}$$

The Hartley transform produces REAL output for a REAL input, and is its own inverse. It therefore can have computational advantages over the DISCRETE FOURIER TRANSFORM, although analytic expressions are usually more complicated for the Hartley transform.

The discrete version of the Hartley transform can be written explicitly as

$$\mathscr{H}[a]\equiv\frac{1}{\sqrt{N}}\sum_{n=0}^{N-1}a_n\left[\cos\left(\frac{2\pi kn}{N}\right)-\sin\left(\frac{2\pi kn}{N}\right)\right] \tag{3}$$

$$=\Re\mathscr{F}[a]-\Im\mathscr{F}[a], \tag{4}$$

where $\mathscr{F}$ denotes the FOURIER TRANSFORM. The Hartley transform obeys the CONVOLUTION property

$$\mathscr{H}[a*b]_k=\tfrac{1}{2}\left(A_kB_k-\bar{A}_k\bar{B}_k+A_k\bar{B}_k+\bar{A}_kB_k\right), \tag{5}$$

where

$$\bar{a}_0\equiv a_0 \tag{6}$$

$$\bar{a}_{n/2}\equiv a_{n/2} \tag{7}$$

$$\bar{a}_k\equiv a_{n-k} \tag{8}$$

(Arndt). Like the FAST FOURIER TRANSFORM, there is a "fast" version of the Hartley transform. A decimation in time algorithm makes use of

$$\mathscr{H}_n^{\text{left}}[a]\equiv\mathscr{H}_{n/2}[a^{\text{even}}]+\mathscr{X}\mathscr{H}_{n/2}[a^{\text{odd}}] \tag{9}$$

$$\mathscr{H}_n^{\text{right}}[a]\equiv\mathscr{H}_{n/2}[a^{\text{even}}]-\mathscr{X}\mathscr{H}_{n/2}[a^{\text{odd}}], \tag{10}$$

where $\mathscr{X}$ denotes the sequence with elements

$$a_n\cos\left(\frac{\pi n}{N}\right)-\bar{a}_n\sin\left(\frac{\pi n}{N}\right). \tag{11}$$

A decimation in frequency algorithm makes use of

$$\mathscr{H}_n^{\text{even}}[a]=\mathscr{H}_{n/2}\left[a^{\text{left}}+a^{\text{right}}\right], \tag{12}$$

$$\mathscr{H}_n^{\text{odd}}[a]=\mathscr{H}_{n/2}\left[\mathscr{X}\left(a^{\text{left}}-a^{\text{right}}\right)\right]. \tag{13}$$

The DISCRETE FOURIER TRANSFORM

$$A_k\equiv\mathscr{F}[a]=\sum_{n=0}^{N-1}e^{-2\pi ikn/N}a_n \tag{14}$$

can be written

$$\begin{bmatrix}A_k\\A_{-k}\end{bmatrix}=\sum_{n=0}^{N-1}\underbrace{\begin{bmatrix}e^{-2\pi ikn/N}&0\\0&e^{-2\pi ikn/N}\end{bmatrix}}_{\mathsf{F}}\begin{bmatrix}a_n\\a_n\end{bmatrix} \tag{15}$$

$$=\sum_{n=0}^{N-1}\underbrace{\frac{1}{2}\begin{bmatrix}1-i&1+i\\1+i&1-i\end{bmatrix}}_{\mathsf{T}^{-1}}\underbrace{\begin{bmatrix}\cos\left(\frac{2\pi kn}{N}\right)&\sin\left(\frac{2\pi kn}{N}\right)\\-\sin\left(\frac{2\pi kn}{N}\right)&\cos\left(\frac{2\pi kn}{N}\right)\end{bmatrix}}_{\mathsf{H}}$$

$$\times\underbrace{\frac{1}{2}\begin{bmatrix}1+i&1-i\\1-i&1+i\end{bmatrix}}_{\mathsf{T}}\begin{bmatrix}a_n\\a_n\end{bmatrix}, \tag{16}$$

so

$$\mathsf{F}=\mathsf{T}^{-1}\mathsf{H}\mathsf{T}. \tag{17}$$

Hash Function

A hash function H projects a value from a set with many (or even an infinite number of) members to a value from a set with a fixed number of (fewer) members. Hash functions are not reversible. A hash function H might, for instance, be defined as $y=H(x)=\lfloor 10x \pmod 1\rfloor$, where $x\in\mathbb{R}$, $y\in[0, 9]$, and $\lfloor x\rfloor$ is the floor function.

Hash functions can be used to determine if two objects are equal (possibly with a fixed average number of mistakes). Other common uses of hash functions are checksums over a large amount of data (e.g., the cyclic redundancy check [CRC]) and finding an entry in a database by a key value. The UNIX c-shell (csh) uses a hash table to store the location of executable programs. As a result adding new executables in a user's search path requires regeneration of the hash table using the `rehash` command before these programs can be executed without specifying the complete path.

To illustrate the use of hash functions in database lookups, consider a database consisting of an array containing an index n, a name, and a telephone number, with names listed in arbitrary order.

n	Name	Number
0	Parker	12345
1	(empty)	
2	Davis	43534
3	Harris	32452
4	Corea	46532
5	Hancock	96562
6	Brecker	37811
7	(empty)	
$N-1$	Marsalis	54323

To look up Hancock from this array, you would start at the beginning of the array, compare the names, then try the next until the names match. This very simple algorithm finds any entry in 1 to N steps, giving an average seek time of $N/2$. The seek time is therefore proportional to N. A much faster result can generally be achieved, if the database is sorted.

n	Name
0	Brecker
1	Corea
2	Davis
3	Hancock
4	Harris
5	Marsalis
6	Parker
7	(empty)
$N-1$	(empty)

An efficient algorithm on this sorted array first checks entry $N/2$, and then recursively uses bisection to check entries in intervals $[0, N/2-1]$ or $[N/2+1, N-1]$, depending wether the most recently looked-up name precedes or succeeds the name sought. The average seek time of this procedure this is proportional to $\ln N$.

The idea behind using a hash function here is that although the possible number of combinations of characters in a name is quite large, only a subset of

them is usually found in practice (i.e., names such as "Kwqrst" are much less common than names like "Jones.") Therefore, when you insert an entry into the database at an index that can somehow be calculated using a key (which is also available at the time you search for it), you might be able to find it later at the first location you check.

Consider the following simple example in which the hash function H is simply the sum of ASCII codes of characters in a name (considered to be all in lower-case) computed mod $N = 13$.

Name	H
Brecker	6
Corea	2
Davis	2
Hancock	12
Harris	12
Marsalis	2
Parker	8

The above example illustrates that the hash function can give the same results for different keys. This difficulty is typically circumvented by introducing a second hash function H_2 whose results are designed to be completely different from that of H. For illustrative purposes, let H_2 be one plus the bitwise exclusive or of all codes in a name (again taken as all lower-case) mod $N - 1$. This gives the following table.

Name	H_2
Brecker	11
Corea	3
Davis	10
Hancock	4
Harris	8
Marsalis	3
Parker	8

A new index can then be calculated as the sum of the first index and H_2 (mod N) until an empty slot is found where new data can be stored. Note that when using H_2 as an offset to walk through the database, it is not, in general, guaranteed that any key will eventually reach any slot. However, for certain values of N, namely N a PRIME NUMBER, such behavior *is* guaranteed, so N is always chosen to be PRIME. After computing H_2 with $N = 13$ (a PRIME), the above phone list would look like this for names added in alphabetic order.

Index	Key	Compares To Find
0	(empty)	
1	(empty)	
2	Corea	1
3	Hancock	2
4	(empty)	
5	Marsalis	2
6	Brecker	1
7	Harris	2
8	Parker	1
9	(empty)	
10	(empty)	
11	(empty)	
12	Davis	2

The average seek time for locating a name in this table depends on the kind of data, N, and the quality of the hash functions used. However, for reasonable choices of hash functions, it will be much smaller than $\ln N$.

See also COLLISION-FREE HASH FUNCTION, CRYPTOGRAPHIC HASH FUNCTION, CYCLIC REDUNDANCY CHECK, ONE-WAY HASH FUNCTION, HASH TABLE, UNIVERSAL HASH FUNCTION

Hash Table

A database accessed by one or more HASH FUNCTIONS.

See also HASH FUNCTION

HashLife

A LIFE ALGORITHM that achieves remarkable speed by storing subpatterns in a HASH FUNCTION table, and using them to skip forward, sometimes thousands of generations at a time. HashLife takes tremendous amounts of memory and can't show patterns at every step, but can quickly calculate the outcome of a pattern that takes millions of generations to complete.

See also HASH FUNCTION, LIFE

Hasse Diagram

A graphical rendering of a PARTIALLY ORDERED SET displayed via the COVER relation of the PARTIALLY ORDERED SET with an implied upward orientation. A point is drawn for each element of the POSET, and line segments are drawn between these points according to the following two rules:

1. If $x < y$ in the poset, then the point corresponding to x appears lower in the drawing than the point corresponding to y.
2. The line segment between the points corresponding to any two elements x and y of the poset is included in the drawing IFF x covers y or y covers x.

Hasse diagrams are also called UPWARD DRAWINGS.

A Hasse diagram of a GRAPH may be generated using `HasseDiagram[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Hasse Principle

A collection of equations satisfies the Hasse principle if, whenever one of the equations has solutions in $\mathbb{R}$ and all the $\mathbb{Q}_p$, then the equations have solutions in the RATIONALS $\mathbb{Q}$. Examples include the set of equations

$$ax^2 + bxy + cy^2 = 0$$

with a, b, and c INTEGERS, and the set of equations

$$x^2 + y^2 = a$$

for a rational. The trivial solution $x = y = 0$ is usually not taken into account when deciding if a collection of homogeneous equations satisfies the Hasse principle. The Hasse principle is sometimes called the local-global principle.

Hasse's Resolution Modulus Theorem

The JACOBI SYMBOL $(a/y) = \chi(y)$ as a CHARACTER can be extended to the KRONECKER SYMBOL $(f(a)/y) = \chi^*(y)$ so that $\chi^*(y) = \chi(y)$ whenever $\chi(y) \neq 0$. When y is RELATIVELY PRIME to $f(a)$, then $\chi^*(y) \neq 0$, and for NONZERO values $\chi^*(y_1) = \chi^*(y_2)$ IFF $y_1 \equiv y_2 \bmod^+ f(a)$. In addition, $|f(a)|$ is the minimum value for which the latter congruence property holds in any extension symbol for $\chi(y)$.

Hat-Box Theorem

ARCHIMEDES' HAT-BOX THEOREM

Haupt-Exponent

The smallest exponent e for which $b^e \equiv 1 \pmod 1$, where b and n are given numbers, is called the haupt-exponent (or sometimes "ORDER") of $b \pmod n$. The number of bases having a haupt-exponent e is $\phi(e)$, where $\phi(e)$ is the TOTIENT FUNCTION. Cunningham (1922) published the haupt-exponents for primes to 25409 and bases 2, 3, 5, 6, 7, 10, 11, and 12.

Haupt-exponents exists for n which are not factors of b. For example, the haupt-exponent of 10 (mod 7) is 6, since

$$10^6 \equiv 1 \pmod 7.$$

The haupt-exponent of 10 mod an integer n relatively prime to 10 gives the period of the DECIMAL EXPANSION of the reciprocal of n (Glaisher 1878, Lehmer 1941). For example, the haupt-exponent of 10 (mod 13) is 6, and

$$\tfrac{1}{13} = 0.0\overline{769230},$$

which has period 6. The haupt-exponent of 2 mod an integer n relatively prime to 2 gives the multiplicative order of 2 (mod $2n+1$) (Golomb 1961).

The following table gives the first few haupt-exponents for bases b (mod p) with $p = 1, 2, \ldots$.

b	Sloane	haupt-exponents
2	A002326	2, 4, 3, 6, 10, 12, 4, 8, 18, 6, 11, 20, 18, ...
3	A050975	1, 2, 4, 6, 2, 4, 5, 3, 6, 4, 16, 18, 4, 5, ...
4	A050976	1, 2, 3, 3, 5, 6, 2, 4, 9, 3, 11, 10, 9, 14, ...
5	A050977	1, 2, 1, 2, 6, 2, 6, 5, 2, 4, 6, 4, 16, 6, 9, ...

Hausdorff

HAUSDORFF SPACE

Hausdorff Axioms

The axioms formulated by Hausdorff (1914) for his concept of a TOPOLOGICAL SPACE. These axioms describe the properties satisfied by subsets of elements x in a NEIGHBORHOOD SET E of x.

1. There corresponds to each point x at least one NEIGHBORHOOD $U(x)$, and each NEIGHBORHOOD $U(x)$ contains the point x.
2. If $U(x)$ and $V(x)$ are two NEIGHBORHOODS of the same point x, there must exist a NEIGHBORHOOD $W(x)$ that is a subset of both.
3. If the point y lies in $U(x)$, there must exist a NEIGHBORHOOD $U(y)$ that is a SUBSET of $U(x)$.
4. For two different points x and y, there are two corresponding NEIGHBORHOODS $U(x)$ and $U(y)$ with no points in common.

See also HAUSDORFF SPACE, TOPOLOGICAL SPACE

Hausdorff Dimension

Informally, SELF-SIMILAR objects with parameters N and s are described by a power law such as

$$N = s^d,$$

where

$$d = \frac{\ln N}{\ln s}$$

is the "DIMENSION" of the scaling law, known as the Hausdorff dimension.

Formally, let A be a SUBSET of a METRIC SPACE X. Then the Hausdorff dimension $D(A)$ of A is the

infimum of $d \geq 0$ such that the d-dimensional Hausdorff measure of A is 0 (which need not be an integer).

In many cases, the Hausdorff dimension correctly describes the correction term for a resonator with fractal perimeter in Lorentz's conjecture. However, in general, the proper dimension to use turns out to be the Minkowski-Bouligand dimension (Schroeder 1991).

Hausdorff Measure

Let X be a metric space, A be a subset of X, and d a number ≥ 0. The d-dimensional Hausdorff measure of A, $H^d(A)$, is the infimum of positive numbers y such that for every $r > 0$, A can be covered by a countable family of closed sets, each of diameter less than r, such that the sum of the dth powers of their diameters is less than y. Note that $H^d(A)$ may be infinite, and d need not be an integer.

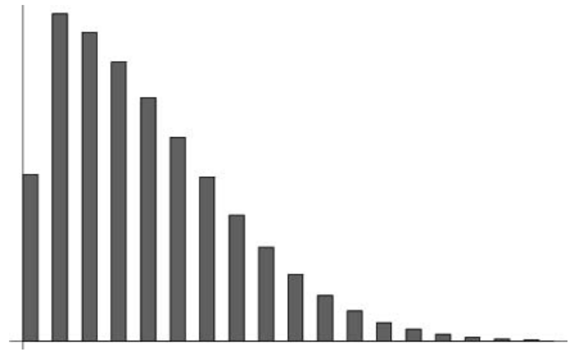
h-Cobordism

An h-cobordism is a COBORDISM W between two MANIFOLDS M_1 and M_2 such that W is SIMPLY CONNECTED and the inclusion maps $M_1 \to W$ and $M_2 \to W$ are HOMOTOPY equivalences.

h-Cobordism Theorem

If W is a SIMPLY CONNECTED, COMPACT MANIFOLD with a boundary that has two components, M_1 and M_2, such that inclusion of each is a HOMOTOPY equivalence, then W is DIFFEOMORPHIC to the product $M_1 \times [0, 1]$ for $\dim(M_1) \geq 5$. In other words, if M and M' are two simply connected MANIFOLDS of DIMENSION ≥ 5 and there exists an H-COBORDISM W between them, then W is a product $M \times I$ and M is DIFFEOMORPHIC to M'.



The proof of the h-cobordism theorem can be accomplished using SURGERY. A particular case of the h-cobordism theorem is the POINCARÉ CONJECTURE in dimension $n \geq 5$. Smale proved this theorem in 1961.

Heads-Minus-Tails Distribution

A fair COIN is tossed an even $2n$ number of times. Let $D \equiv |H - T|$ be the absolute difference in the number of heads and tails obtained. Then the probability distribution is given by

$$P(D = 2k) = \begin{cases} \left(\frac{1}{2}\right)^{2n} \binom{2n}{n} & k = 0 \\ 2\left(\frac{1}{2}\right)^{2n} \binom{2n}{n+k} & k = 1, 2, \ldots, \end{cases}$$

where $P(D = 2k - 1) = 0$. The most probable value of D is $D = 2$, and the expectation value is

$$\langle D_n \rangle = \frac{n\binom{2n}{n}}{2^{2n-1}}.$$

The generating function for $\langle D \rangle$ is given by

$$\sum \langle D_n \rangle x^{n-1} = (1-x)^{-3/2} = 1 + \tfrac{3}{2}x + \tfrac{15}{8}x^2 + \tfrac{35}{16}x^3 + \ldots$$

(Sloane's A001803 and A046161; Abramowitz and Stegun 1972, Prévost 1933; Hughes 1995). These numbers also arise in 1-D RANDOM WALKS.

Heap

A SEQUENCE $\{a_n\}_{n=1}^N$ forms a (binary) heap if it satisfies $a_{\lfloor j/2 \rfloor} \leq a_j$ for $2 \leq j \leq N$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION, which is equivalent to $a_i < a_{2i}$ and

$a_i < a_{2i+1}$ for $1 \le i \le (i-1)/2$. The first member must therefore be the smallest. A heap can be viewed as a labeled BINARY TREE in which the label of the ith node is smallest than the labels of any of its descendents (Skiena 1990, p. 35). Heaps support arbitrary insertion and seeking/deletion of the minimum value in $\mathcal{O}(\ln n)$ times per update (Skiena 1990, p. 38).

A list can be converted to a heap in $\mathcal{O}(n)$ times using an algorithm due to Floyd (1964). A binary heap can be generated from a PERMUTATION p using `Heapify[p]` in the *Mathematica* add-on package ``DiscreteMath`Combinatorica` `` (which can be loaded with the command ``<<DiscreteMath` ``). For example, given the RANDOM PERMUTATION $\{6, 2, 7, 9, 5, 3, 4, 8, 10, 1\}$, Floyd's algorithm gives the heap $\{1, 2, 3, 8, 5, 7, 4, 9, 10, 6\}$ (left figure). The right figure shows a heap containing 30 elements.

A PERMUTATION can be tested to see if it is a heap using the following *Mathematica* functions.

```
<<DiscreteMath`Combinatorica`;
 HeapQ[a_List?PermutationQ] := Module[{i, n
= Length[a]},
  And @@ Table[a[[Floor[i/2]]] < a[[i]], {i,
2, n}]
 ]
```

n	heaps
1	{1}
2	{1, 2}
3	{1, 2, 3}, {1, 3, 2}
4	{1, 2, 3, 4}, {1, 2, 4, 3}, {1, 3, 2, 4}

The numbers of heaps on $n = 1, 2, \ldots$ elements are 1, 1, 2, 3, 8, 20, 80, 896, 3360, ... (Sloane's A056971), the first few of which are summarized in the above table. The number of heaps of l levels (or equivalently, the number of heaps of $2^l - 1$ elements) is given by the RECURRENCE RELATION

$$S_l = \binom{2^l - 2}{2^{l-1} - 1} S_{l-1}^2$$

with $S_1 = 1$ (Skiena 1990, p. 36), the values of which for $l = 1, 2, \ldots$ are 1, 2, 80, 21964800, 74836825861835980800000, ... (Sloane's A056972).

Heat Conduction Equation

A PARTIAL DIFFERENTIAL diffusion equation OF THE FORM

$$\frac{\partial T}{\partial t} = \kappa \nabla^2 T. \tag{1}$$

Physically, the equation commonly arises in situations where κ is the thermal diffusivity and T the temperature.

The 1-D heat conduction equation is

$$\frac{\partial T}{\partial t} = \kappa \frac{\partial^2 T}{\partial x^2}. \tag{2}$$

This can be solved by SEPARATION OF VARIABLES using

$$T(x, t) = X(x)T(t). \tag{3}$$

Then

$$X \frac{dT}{dt} = \kappa T \frac{d^2 X}{dx^2}. \tag{4}$$

Dividing both sides by κXT gives

$$\frac{1}{\kappa T}\frac{dT}{dt} = \frac{1}{X}\frac{d^2 X}{dx^2} = -\frac{1}{\lambda^2}, \tag{5}$$

where each side must be equal to a constant. Anticipating the exponential solution in T, we have picked a negative separation constant so that the solution remains finite at all times and λ has units of length. The T solution is

$$T(t) = Ae^{-\kappa t/\lambda^2}, \tag{6}$$

and the X solution is

$$X(x) = C \cos\left(\frac{x}{\lambda}\right) + D \sin\left(\frac{x}{\lambda}\right). \tag{7}$$

The general solution is then

$$\begin{aligned} T(x, t) &= T(t)X(x) \\ &= Ae^{-\kappa t/\lambda^2}\left[C \cos\left(\frac{x}{\lambda}\right) + D \sin\left(\frac{x}{\lambda}\right)\right] \\ &= e^{-\kappa t/\lambda^2}\left[D \cos\left(\frac{x}{\lambda}\right) + E \sin\left(\frac{x}{\lambda}\right)\right]. \end{aligned} \tag{8}$$

If we are given the boundary conditions

$$T(0, t) = 0 \tag{9}$$

and

$$T(L, t) = 0, \tag{10}$$

then applying (9) to (8) gives

$$D \cos\left(\frac{x}{\lambda}\right) = 0 \Rightarrow D = 0, \tag{11}$$

and applying (10) to (8) gives

$$E \sin\left(\frac{L}{\lambda}\right) = 0 \Rightarrow \frac{L}{\lambda} = n\pi \Rightarrow \lambda = \frac{L}{n\pi}, \tag{12}$$

so (8) becomes

$$T_n(x, t) = E_n e^{-\kappa(n\pi/L)^2 t} \sin\left(\frac{n\pi x}{L}\right). \tag{13}$$

Since the general solution can have any n,

$$T(x, t) = \sum_{n=1}^{\infty} c_n \sin\left(\frac{n\pi x}{L}\right) e^{-\kappa(n\pi/L)^2 t}. \tag{14}$$

Now, if we are given an initial condition $T(x, 0)$, we have

$$T(x, 0) = \sum_{n=1}^{\infty} c_n \sin\left(\frac{n\pi x}{L}\right). \tag{15}$$

Multiplying both sides by $\sin(m\pi x/L)$ and integrating from 0 to L gives

$$\begin{aligned} &\int_0^L \sin\left(\frac{m\pi x}{L}\right) T(x, 0)\, dx \\ &= \int_0^L \sum_{n=1}^{\infty} c_n \sin\left(\frac{m\pi x}{L}\right) \sin\left(\frac{n\pi x}{L}\right) dx. \end{aligned} \tag{16}$$

Using the ORTHOGONALITY of $\sin(nx)$ and $\sin(mx)$,

$$\begin{aligned} \sum_{n=1}^{\infty} c_n \int_0^L \sin\left(\frac{n\pi x}{L}\right) \sin\left(\frac{m\pi x}{L}\right) dx &= \sum_{n=1}^{\infty} \tfrac{1}{2}\pi\delta_{mn} c_n \\ = \tfrac{1}{2}\pi c_m &= \int_0^L \sin\left(\frac{m\pi x}{L}\right) T(x, 0)\, dx, \end{aligned} \tag{17}$$

so

$$c_n = \frac{2}{\pi}\int_0^L \sin\left(\frac{m\pi x}{L}\right) T(x, 0)\, dx. \tag{18}$$

If the boundary conditions are replaced by the requirement that the derivative of the temperature be zero at the edges, then (9) and (10) are replaced by

$$\left.\frac{\partial T}{\partial x}\right|_{(0, t)} = 0 \tag{19}$$

$$\left.\frac{\partial T}{\partial x}\right|_{(L, t)} = 0. \tag{20}$$

Following the same procedure as before, a similar

answer is found, but with sine replaced by cosine:

$$T(x, t) = \sum_{n=1}^{\infty} c_n \cos\left(\frac{n\pi x}{L}\right) e^{-\kappa(n\pi/L)^2 t}, \quad (21)$$

where

$$c_n = \frac{2}{\pi} \int_0^L \cos\left(\frac{m\pi x}{L}\right) \left.\frac{\partial T(x, 0)}{\partial x}\right|_{t=0} dx. \quad (22)$$

Heat Conduction EquationDisk

To solve the HEAT CONDUCTION EQUATION on a 2-D disk of radius $R = 1$, try to separate the equation using

$$T(r, \theta, t) = R(r)\Theta(\theta)T(t). \quad (1)$$

Writing the θ and r terms of the LAPLACIAN in SPHERICAL COORDINATES gives

$$\nabla^2 = \frac{d^2R}{dr^2} + \frac{2}{r}\frac{dR}{dr} + \frac{1}{r^2}\frac{d^2\Theta}{d\theta^2}, \quad (2)$$

so the HEAT CONDUCTION EQUATION becomes

$$\frac{R\Theta}{\kappa}\frac{d^2T}{dt^2} = \frac{d^2R}{dr^2}\Theta T + \frac{2}{r}\frac{dR}{dr}\Theta T + \frac{1}{r^2}\frac{d^2\Theta}{d\theta^2} RT. \quad (3)$$

Multiplying through by $r^2/R\Theta T$ gives

$$\frac{r^2}{\kappa T}\frac{d^2T}{dt^2} = \frac{r^2}{R}\frac{d^2R}{dr^2} + \frac{2r}{R}\frac{dR}{dr} + \frac{d^2\Theta}{d\theta^2}\frac{1}{\Theta}. \quad (4)$$

The θ term can be separated.

$$\frac{d^2\Theta}{d\theta^2}\frac{1}{\Theta} = -n(n+1), \quad (5)$$

which has a solution

$$\Theta(\theta) = A\cos\left[\sqrt{n(n+1)}\theta\right] + B\sin\left[\sqrt{n(n+1)}\theta\right]. \quad (6)$$

The remaining portion becomes

$$\frac{r^2}{\kappa T}\frac{d^2T}{dt^2} = \frac{r^2}{R}\frac{d^2R}{dr^2} + \frac{2r}{R}\frac{dR}{dr} - n(n+1). \quad (7)$$

Dividing by r^2 gives

$$\frac{1}{\kappa T}\frac{d^2T}{dt^2} = \frac{1}{R}\frac{d^2R}{dr^2} + \frac{2}{rR}\frac{dR}{dr} - \frac{n(n+1)}{r^2} = -\frac{1}{\lambda^2}, \quad (8)$$

where a NEGATIVE separation constant has been chosen so that the t portion remains finite

$$T(t) = Ce^{-\kappa t/\lambda^2}. \quad (9)$$

The radial portion then becomes

$$\frac{1}{R}\frac{d^2R}{dr^2} + \frac{2}{rR}\frac{dR}{dr} - \frac{n(n+1)}{r^2} + \frac{1}{\lambda^2} = 0 \quad (10)$$

$$r^2\frac{d^2R}{dr^2} + 2r\frac{dR}{dr} + \left[\frac{r^2}{\lambda^2} - n(n+1)\right]R = 0, \quad (11)$$

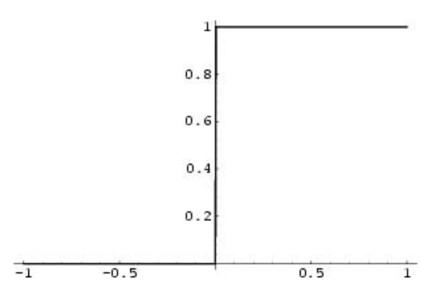
which is the SPHERICAL BESSEL DIFFERENTIAL EQUATION. If the initial temperature is $T(r, 0) = 0$ and the boundary condition is $T(1, t) = 1$, the solution is

$$T(r, t) = 1 - 2\sum_{n=1}^{\infty} \frac{J_0(\alpha_n r)}{\alpha_n J_1(\alpha_n)} e^{\alpha_n^2 t}, \quad (12)$$

where α_n is the nth POSITIVE zero of the BESSEL FUNCTION OF THE FIRST KIND $J_0(x)$.

Heaviside Calculus

The study, first developed by Boole, of SHIFT-INVARIANT OPERATORS which are polynomials in the DIFFERENTIAL OPERATOR $\tilde{D}$. Heaviside calculus can be used to solve any ORDINARY DIFFERENTIAL EQUATION OF THE FORM



$$p(\tilde{D})f(x) = g(x)$$

with $p(0) \neq 0$, and is frequently implemented using LAPLACE TRANSFORMS.

See also DIFFERENTIAL OPERATOR, LAPLACE TRANSFORM, SHIFT-INVARIANT OPERATOR

References
Rota, G.-C.; Kahaner, D.; Odlyzko, A. "On the Foundations of Combinatorial Theory. VIII: Finite Operator Calculus." *J. Math. Anal. Appl.* **42**, 684–60, 1973.

Heaviside Step Function

A discontinuous "step" function also called the unit step, and defined by

$$H(x) = \begin{cases} 0 & x < 0 \\ \frac{1}{2} & x = 0 \\ 1 & x > 0. \end{cases} \quad (1)$$

It is related to the BOXCAR FUNCTION by

$$\prod(x) = H\left(x + \tfrac{1}{2}\right) - H\left(x - \tfrac{1}{2}\right) \quad (2)$$

and can be defined in terms of the SGN function by

$$H(x)=\tfrac{1}{2}[1+\operatorname{sgn}(x)]. \tag{3}$$

The shorthand notation

$$H_c(x)\equiv H(x-c) \tag{4}$$

is sometimes also used. The Heaviside step function is given by the *Mathematica* command `UnitStep[x]`. The DERIVATIVE is given by

$$\frac{d}{dx}H(x)=\delta(x), \tag{5}$$

where $\delta(x)$ is the DELTA FUNCTION, and the step function is related to the RAMP FUNCTION $R(x)$ by

$$\frac{d}{dx}R(x)=-H(x) \tag{6}$$

$$R(x)=xH(x) \tag{7}$$

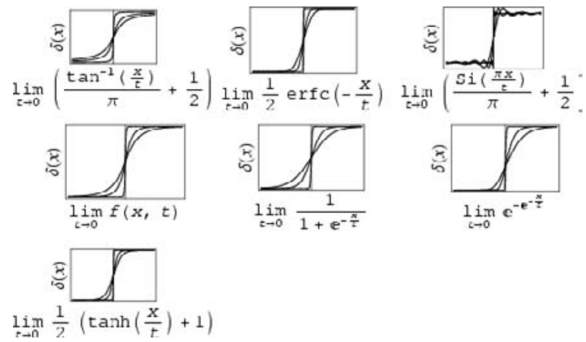
$$R(x)=H(x)*H(x), \tag{8}$$

where $*$ denotes CONVOLUTION.

Bracewell (1999) gives many identities, some of which include the following. Letting $*$ denote the CONVOLUTION,

$$H(x)*f(x)=\int_{-\infty}^{x} f(x')\,dx' \tag{9}$$

$$H(t)*H(t)=\int_{-\infty}^{\infty} H(u)H(t-u)\,du \tag{10}$$



$$=H(0)\int_{0}^{\infty} H(t-u)\,du$$

$$=H(0)H(t)\int_{0}^{t} du=tH(t). \tag{11}$$

In addition,

$$H(ax+b)=H\left(x+\frac{b}{a}\right)H(a)+H\left(-x-\frac{b}{a}\right)H(-a)$$

$$=\begin{cases} H\left(x+\dfrac{b}{a}\right) & a>0 \\ H\left(-x-\dfrac{b}{a}\right) & a<0. \end{cases} \tag{12}$$

The Heaviside step function can be defined by the following limits,

$$H(x)=\lim_{t\to 0}\left[\tfrac{1}{2}+\frac{1}{\pi}\tan^{-1}\left(\frac{x}{t}\right)\right] \tag{13}$$

$$=\frac{1}{\sqrt{\pi}}\lim_{t\to 0}\int_{-x}^{\infty} t^{-1}e^{-u^2/t^2}\,du$$

$$=\frac{1}{2}\lim_{t\to 0}\operatorname{erfc}\left(-\frac{x}{t}\right) \tag{14}$$

$$=\frac{1}{\pi}\lim_{t\to 0}\int_{-\infty}^{x} t^{-1}\operatorname{sinc}\left(\frac{u}{t}\right)du$$

$$=\frac{1}{\pi}\lim_{t\to 0}\int_{-\infty}^{x}\frac{1}{u}\sin\left(\frac{u}{t}\right) \tag{15}$$

$$=\frac{1}{2}+\frac{1}{\pi}\lim_{t\to 0}\operatorname{si}\left(\frac{\pi x}{t}\right) \tag{16}$$

$$=\lim_{t\to 0}\begin{cases}\tfrac{1}{2}e^{x/t} & \text{for } x\le 0\\ 1-\tfrac{1}{2}e^{-x/t} & \text{for } x\ge 0\end{cases} \tag{17}$$

$$=\lim_{t\to 0}\frac{1}{1+e^{-x/t}} \tag{18}$$

$$=\lim_{t\to 0} e^{e^{-x/t}} \tag{19}$$

$$=\frac{1}{2}\lim_{t\to 0}\left[1+\tanh\left(\frac{x}{t}\right)\right] \tag{20}$$

$$=\lim_{t\to 0}\int_{-\infty}^{x} t^{-1}\Lambda\left(\frac{x-\tfrac{1}{2}t}{t}\right)dx, \tag{21}$$

where $\operatorname{erfc}(x)$ is the ERFC function, $\operatorname{si}(x)$ is the SINE INTEGRAL, $\operatorname{sinc} x$ is the SINC FUNCTION, and $\Lambda(x)$ is the one-argument TRIANGLE FUNCTION. The first four of these are illustrated above for $t=0.2$, 0.1, and 0.01.

Of course, any monotonic function with constant unequal horizontal asymptotes is a Heaviside step function under appropriate scaling and possible reflection. The FOURIER TRANSFORM of the Heaviside step function is given by

$$\mathscr{F}[H(x)] = \int_{-\infty}^{\infty} e^{-2\pi ikx} H(x)\, dx = \frac{1}{2}\left[\delta(k) - \frac{i}{\pi k}\right], \quad (22)$$

where $\delta(k)$ is the DELTA FUNCTION.

Heawood Conjecture

The bound for the number of colors which are SUFFICIENT for MAP COLORING on a surface of GENUS g,

$$\gamma(g) = \left\lfloor \tfrac{1}{2}(7 + \sqrt{48g+1}) \right\rfloor$$

is the best possible, where $\lfloor x \rfloor$ is the FLOOR FUNCTION. $\gamma(g)$ is called the CHROMATIC NUMBER, and the first few values for $g = 0, 1, ...$ are 4, 7, 8, 9, 10, 11, 12, 12, 13, 13, 14, ... (Sloane's A000934).

The fact that $\gamma(g)$ is also NECESSARY was proved by Ringel and Youngs (1968) with two exceptions: the SPHERE (PLANE), and the KLEIN BOTTLE. When the FOUR-COLOR THEOREM was proved in 1976, the KLEIN BOTTLE was left as the only exception, in that the Heawood formula gives seven, but the correct bound is six (as demonstrated by the FRANKLIN GRAPH). The four most difficult cases to prove in the FOUR-COLOR THEOREM were $g = 59$, 83, 158, and 257.

Heawood graph

torus coloring

The seven-color torus map on 14 nodes illustrated above. The Heawood graph is a CAGE GRAPH and is 4-transitive, but not 5-transitive (Harary 1994, p. 173). The Heawood graph is the point/line INCIDENCE GRAPH on the FANO PLANE (Royle).

Hecke Operator

A family of operators mapping each SPACE M_k of MODULAR FORMS onto itself. For a fixed integer k and any POSITIVE INTEGER n, the Hecke operator T_n is defined on the set M_k of entire modular forms of weight k by

$$(T_n f)(\tau) = n^{k-1} \sum_{d|n} d^{-k} \sum_{b=0}^{d-1} f\left(\frac{n\tau + bd}{d^2}\right). \quad (1)$$

For n a PRIME p, the operator collapses to

$$(T_p f)(\tau) = p^{k-1} f(p\tau) + \frac{1}{p} \sum_{b=0}^{p-1} \left(\frac{\tau + b}{p}\right). \quad (2)$$

If $f \in M_k$ has the FOURIER SERIES

$$f(\tau) = \sum_{m=0}^{\infty} c(m) e^{2\pi i m \tau}, \quad (3)$$

then $T_n f$ has FOURIER SERIES

$$(T_n f)(\tau) = \sum_{m=0}^{\infty} \gamma_n(m) e^{2\pi i m \tau}, \quad (4)$$

where

$$\gamma_n(m) = \sum_{d|(n,\ m)} d^{k-1} c\left(\frac{mn}{d^2}\right) \quad (5)$$

(Apostol 1997, p. 121).

If $(m,\ n) = 1$, the Hecke operators obey the composition property

$$T_m T_n = T_{mn}. \quad (6)$$

Any two Hecke operators $T(n)$ and $T(m)$ on M_k COMMUTE with each other, and moreover

$$T(m)T(n) = \sum_{d|(m,\ n)} d^{k-1} T\left(\frac{mn}{d^2}\right) \quad (7)$$

(Apostol 1997, pp. 126–27).

Each Hecke operator T_n has eigenforms when the dimension of M_k is 1, so for $k = 4$, 6, 8, 10, and 14, the eigenforms are the EISENSTEIN SERIES G_4, G_6, G_8, G_{10}, and G_{14}, respectively. Similarly, each T_n has eigenforms when the dimension of the set of CUSP FORMS $M_{k,\ 0}$ is 1, so for $k = 12$, 16, 18, 20, 22, and 26, the eigenforms are Δ, ΔG_4, ΔG_6, ΔG_8, ΔG_{10}, and ΔG_{14}, respectively, where Δ is the MODULAR DISCRIMINANT of the WEIERSTRASS ELLIPTIC FUNCTION (Apostol 1997, p. 130).

Hecke Ring

HECKE ALGEBRA

Hectogon

A 100-sided POLYGON, virtually indistinguishable in appearance from a CIRCLE except at very high magnification.

Hedgehog

An envelope parameterized by its GAUSS MAP. The PARAMETRIC EQUATIONS for a hedgehog are

$$x = p(\theta) \cos \theta + p'(\theta) \sin \theta$$

$$y = p(\theta) \sin \theta + p'(\theta) \cos \theta.$$

A plane convex hedgehog has at least four VERTICES where the CURVATURE has a stationary value. A plane convex hedgehog of constant width has at least six VERTICES (Martinez-Maure 1996).

Heegaard Diagram

A diagram expressing how the gluing operation that connects the HANDLEBODIES involved in a HEEGAARD SPLITTING proceeds, usually by showing how the meridians of the HANDLEBODY are mapped.

See also HANDLEBODY, HEEGAARD SPLITTING

References

Rolfsen, D. *Knots and Links.* Wilmington, DE: Publish or Perish Press, p. 239, 1976.

Heegaard Splitting

A Heegaard splitting of a connected orientable 3-MANIFOLD M is any way of expressing M as the UNION of two (3,1)-HANDLEBODIES along their boundaries. The boundary of such a (3,1)-HANDLEBODY is an orientable SURFACE of some GENUS, which determines the number of HANDLES in the (3,1)-HANDLEBODIES. Therefore, the HANDLEBODIES involved in a Heegaard splitting are the same, but they may be glued together in a strange way along their boundary. A diagram showing how the gluing is done is known as a HEEGAARD DIAGRAM.

Heegner Number

The values of $-d$ for which IMAGINARY QUADRATIC FIELDS $\mathbb{Q}(\sqrt{-d})$ are uniquely factorable into factors OF THE FORM $a+b\sqrt{-d}$). Here, a and b are half-integers, except for $d=1$ and 2, in which case they are INTEGERS. The Heegner numbers therefore correspond to DISCRIMINANTS $-d$ which have CLASS NUMBER $h(-d)$ equal to 1, except for Heegner numbers -1 and -2, which correspond to $d=-4$ and -8, respectively.

The determination of these numbers is called GAUSS'S CLASS NUMBER PROBLEM, and it is now known that there are only nine Heegner numbers: -1, -2, -3, -7, -11, -19, -43, -67, and -163 (Sloane's A003173), corresponding to discriminants -4, -8, -3, -7, -11, -19, -43, -67, and -163, respectively.

Heilbronn and Linfoot (1934) showed that if a larger d existed, it must be 10^9. Heegner (1952) published a proof that only nine such numbers exist, but his proof was not accepted as complete at the time. Subsequent examination of Heegner's proof show it to be "essentially" correct (Conway and Guy 1996).

The Heegner numbers have a number of fascinating connections with amazing results in PRIME NUMBER theory. In particular, the j-FUNCTION provides stunning connections between e, π, and the ALGEBRAIC INTEGERS. They also explain why Euler's PRIME-GENERATING POLYNOMIAL n^2-n+41 is so surprisingly good at producing PRIMES.

Heesch Number

The Heesch number of a closed plane figure is the maximum number of times that figure can be completely surrounded by copies of itself. The determination of the maximum possible (finite) Heesch number is known as HEESCH'S PROBLEM. The Heesch number of a TRIANGLE, QUADRILATERAL, regular HEXAGON, or any other shape that can TILE or TESSELLATE the plane, is infinity. Conversely, any shape with infinite Heesch number must tile the plane (Eppstein).

A tile invented by R. Ammann has Heesch number is three (Senechal 1995), and Mann has found an infinite family of tiles with Heesch number five (illustrated above), the largest (finite) number known.

Height

The vertical length of an object from top to bottom.

See also LENGTH (SIZE), POLYNOMIAL HEIGHT, WIDTH (SIZE)

Heilbronn Triangle Problem

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Given any arrangement of n points within a UNIT SQUARE, let H_n be the smallest value for which there is at least one TRIANGLE formed from three of the points with AREA $\leq H_n$. The first few values are

$$H_3 = \tfrac{1}{2}$$

$$H_4 = \tfrac{1}{2}$$

$$H_5 = \tfrac{1}{9}\sqrt{3}$$

$$H_6 = \tfrac{1}{8}$$

$$H_7 \geq \tfrac{1}{12}$$

$$H_8 \geq \tfrac{1}{4}(2-\sqrt{3})$$

$$H_9 \geq \tfrac{1}{21}$$

$$H_{10} \geq \tfrac{1}{32}(3\sqrt{17}-11)$$

$$H_{11} \geq \tfrac{1}{27}$$

$$H_{12} \geq \tfrac{1}{33}$$

$$H_{13} \geq 0.030$$

$$H_{14} \geq 0.022$$

$$H_{15} \geq 0.020$$

$$H_{16} \geq 0.0175.$$

Komlós *et al.* (1981, 1982) have shown that there are constants c such that

$$\frac{c \ln n}{n^2} \leq H_n \leq \frac{C}{n^{8/7} - \epsilon},$$

for any $\epsilon > 0$ and all sufficiently large n.

Using an EQUILATERAL TRIANGLE of unit AREA instead gives the constants

$$h_3 = 1$$

$$h_4 = \tfrac{1}{3}$$

$$h_5 = 3 - 2\sqrt{2}$$

$$h_6 = \tfrac{1}{8}.$$

Heisenberg Group

The Heisenberg group H^n in n COMPLEX variables is the GROUP of all (z, t) with $z \in \mathbb{C}^n$ and $t \in \mathbb{R}$ having multiplication

$$(w, t)(z, t') = (w + z, t + t' + \Im[w^* z])$$

where w^* is the adjoint. The Heisenberg group is ISOMORPHIC to the group of MATRICES

$$\begin{bmatrix} 1 & z^{\mathrm{T}} & \frac{1}{2}|z|^2 + it \\ 0 & 1 & z \\ 0 & 0 & 1 \end{bmatrix},$$

and satisfies

$$(z, t)^{-1} = (-z, -t).$$

Every finite-dimensional unitary representation is trivial on Z and therefore factors to a REPRESENTATION of the quotient $\mathbb{C}^n$.

CYCLOID

Helicoid

The MINIMAL SURFACE having a HELIX as its boundary. It is the only RULED MINIMAL SURFACE other than the PLANE (Catalan 1842, do Carmo 1986). For many years, the helicoid remained the only known example of a complete embedded MINIMAL SURFACE of finite topology with infinite CURVATURE. However, in 1992 a second example, known as HOFFMAN'S MINIMAL SURFACE and consisting of a helicoid with a HOLE, was discovered (*Sci. News* 1992). The helicoid is the only non-rotary surface which can glide along itself (Steinhaus 1983, p. 231).

The equation of a helicoid in CYLINDRICAL COORDINATES is

$$z = c\theta. \tag{1}$$

In CARTESIAN COORDINATES, it is

$$\frac{y}{x} = \tan\left(\frac{z}{c}\right). \tag{2}$$

It can be given in parametric form by

$$x = u \cos v \tag{3}$$

$$y = u \sin v \tag{4}$$

$$z = cv, \tag{5}$$

which has an obvious generalization to the ELLIPTIC HELICOID. Writing $z = -cu$ instead of $z = cv$ gives a CONE instead of a helicoid.

The FIRST FUNDAMENTAL FORM coefficients of the helicoid are given by

$$E = 1 \tag{6}$$

$$F = 0 \tag{7}$$

$$G^2 = c^2 + u^2, \tag{8}$$

and the SECOND FUNDAMENTAL FORM coefficients are

$$e = 0 \tag{9}$$

$$f = -\frac{c}{\sqrt{c^2 + u^2}} \tag{10}$$

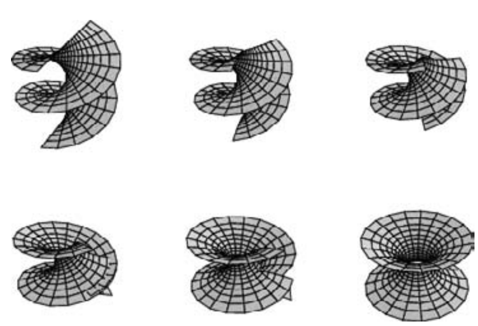
$$g = 0, \tag{11}$$

giving AREA ELEMENT

$$dS = \sqrt{c^2 + u^2}\, du \wedge dv. \tag{12}$$

Integrating over $v \in [0,\ \theta]$ and $u \in [0,\ r]$ then gives

$$S = \int_0^\theta \int_0^r \sqrt{c^2 + u^2}\, du\, dv$$
$$= \tfrac{1}{2}\theta \left[r\sqrt{c^2 + r^2} + c^2 \ln\left(\frac{r + \sqrt{c^2 + r^2}}{c} \right) \right]. \tag{13}$$



The GAUSSIAN CURVATURE is given by

$$K = -\frac{c^2}{(c^2 + u^2)^2}, \tag{14}$$

and the MEAN CURVATURE is

$$H = 0 \tag{15}$$

making the helicoid a MINIMAL SURFACE.

The helicoid can be continuously deformed into a CATENOID by the transformation

$$x(u,\ v) = \cos\alpha \sinh v \sin u + \sin\alpha \cosh v \cos u \tag{16}$$

$$y(u,\ v) = -\cos\alpha \sinh v \cos u + \sin\alpha \cosh v \sin u \tag{17}$$

$$z(u,\ v) = u \cos\alpha + v \sin\alpha, \tag{18}$$

where $\alpha = 0$ corresponds to a helicoid and $\alpha = \pi/2$ to a CATENOID.

If a twisted curve C (i.e., one with TORSION $\tau \neq 0$) rotates about a fixed axis A and, at the same time, is displaced parallel to A such that the speed of displacement is always proportional to the angular velocity of rotation, then C generates a GENERALIZED HELICOID.

Helix

A helix is also called a CURVE OF CONSTANT SLOPE. It can be defined as a curve for which the TANGENT makes a constant ANGLE with a fixed line. The shortest path between two points on a cylinder (one

not directly above the other) is a fractional turn of a helix, as can be seen by cutting the cylinder along one of its sides, flattening it out, and noting that a straight line connecting the points becomes helical upon re-wrapping (Steinhaus 1983, p. 229). It is for this reason that squirrels chasing one another up and around tree trunks follow helical paths.

Helices come in enantiomorphous left- (coils counterclockwise as it "goes away") and right-handed forms (coils clockwise). Standard screws, nuts, and bolts are all right-handed, as are both the helices in a double-stranded molecule of DNA (Gardner 1984, pp. 2–). Large helical structures in animals (such as horns) usually appear in both mirror-image forms, although the teeth of a male narwhal, usually only one which grows into a tusk, are *both* left-handed (Bonner 1951; Gardner 1984, p. 3; Thompson 1992). Gardner (1984) contains a fascinating discussion of helices in plants and animals, including an allusion to Shakespeare's *A Midsummer Night's Dream.*

The helix is a SPACE CURVE with PARAMETRIC EQUATIONS

$$x = r\cos t \tag{1}$$

$$y = r\sin t \tag{2}$$

$$z = ct, \tag{3}$$

where r is the radius of the helix and c is a constant giving the vertical separation of the helix's loops. The CURVATURE of the helix is given by

$$\kappa = \frac{r}{r^2 + c^2}, \tag{4}$$

and the LOCUS of the centers of CURVATURE of a helix is another helix. The ARC LENGTH is given by

$$s = \int \sqrt{x'^2 + y'^2 + z'^2}\,dt = \sqrt{r^2 + c^2}\,t. \tag{5}$$

The TORSION of a helix is given by

$$\tau = \frac{1}{r^2(r^2 + c^2)} \begin{vmatrix} -r\sin t & -r\cos t & r\sin t \\ r\cos t & -r\sin t & -r\cos t \\ c & 0 & 0 \end{vmatrix}$$

$$= \frac{c}{r^2 + c^2}, \tag{6}$$

so

$$\frac{\kappa}{\tau} = \frac{\frac{r}{r^2 + c^2}}{\frac{c}{r^2 + c^2}} = \frac{r}{c}, \tag{7}$$

which is a constant. In fact, LANCRET'S THEOREM states that a NECESSARY and SUFFICIENT condition for a curve to be a helix is that the ratio of CURVATURE to TORSION be constant. The OSCULATING PLANE of the helix is given by

$$\begin{vmatrix} z_1 - r\cos t & z_2 - r\sin t & z_3 - ct \\ -r\sin t & r\cos t & c \\ -r\cos t & -r\sin t & 0 \end{vmatrix} = 0 \tag{8}$$

$$z_1 c\sin t - z_2 c\cos t + (z_3 - ct)r = 0. \tag{9}$$

The MINIMAL SURFACE of a helix is a HELICOID.

Helmholtz Differential Equation

An ELLIPTIC PARTIAL DIFFERENTIAL EQUATION given by

$$\nabla^2 \psi + k^2 \psi = 0, \tag{1}$$

where ψ is a SCALAR FUNCTION and ∇^2 is the scalar LAPLACIAN, or

$$\nabla^2 \mathbf{A} + k^2 \mathbf{A} = 0, \tag{2}$$

where $\mathbf{A}$ is a VECTOR FUNCTION and ∇^2 is the vector Laplacian (Moon and Spencer 1988, pp. 136–43).

When $k = 0$, the Helmholtz differential equation reduces to LAPLACE'S EQUATION. When $k^2 < 0$ (i.e., for imaginary k), the equation becomes the space part of the diffusion equation.

The Helmholtz differential equation can be solved by SEPARATION OF VARIABLES in only 11 coordinate systems, 10 of which (with the exception of CONFOCAL PARABOLOIDAL COORDINATES) are particular cases of the CONFOCAL ELLIPSOIDAL system: CARTESIAN, CONFOCAL ELLIPSOIDAL, CONFOCAL PARABOLOIDAL, CONICAL, CYLINDRICAL, ELLIPTIC CYLINDRICAL, OBLATE SPHEROIDAL, PARABOLOIDAL, PARABOLIC CYLINDRICAL, PROLATE SPHEROIDAL, and SPHERICAL COORDINATES (Eisenhart 1934). LAPLACE'S EQUATION (the Helmholtz differential equation with $k = 0$) is separable in the two additional BISPHERICAL COORDINATES and TOROIDAL COORDINATES.

If Helmholtz's equation is separable in a 3-D coordinate system, then Morse and Feshbach (1953, pp. 509–10) show that

$$\frac{h_1 h_2 h_3}{h_n^2} = f_n(u_n) g_n(u_i, u_j), \tag{3}$$

where $i \neq j \neq n$. The LAPLACIAN is therefore OF THE FORM

$$\nabla^2 = \frac{1}{h_1 h_2 h_3} \left\{ g_1(u_2, u_3) \frac{\partial}{\partial u_1} \left[f_1(u_1) \frac{\partial}{\partial u_1} \right] + g_2(u_1, u_3) \frac{\partial}{\partial u_2} \left[f_2(u_2) \frac{\partial}{\partial u_2} \right] + g_3(u_1, u_3) \frac{\partial}{\partial u_3} \left[f_3(u_3) \frac{\partial}{\partial u_3} \right] \right\}, \tag{4}$$

which simplifies to

$$\nabla^2 = \frac{1}{h_1^2 f_1} \frac{\partial}{\partial u_1} \left[f_1(u_1) \frac{\partial}{\partial u_1} \right] + \frac{1}{h_2^2 f_2} \frac{\partial}{\partial u_2} \left[f_2(u_2) \frac{\partial}{\partial u_2} \right] + \frac{1}{h_3^2 f_3} \frac{\partial}{\partial u_3} \left[f_3(u_3) \frac{\partial}{\partial u_3} \right]. \tag{5}$$

Such a coordinate system obeys the ROBERTSON CONDITION, which means that the STÄCKEL DETERMINANT is OF THE FORM

$$S = \frac{h_1 h_2 h_3}{f_1(u_1) f_2(u_2) f_3(u_3)}. \tag{6}$$

Helmholtz Differential Equation—Bipolar Coordinates

In BIPOLAR COORDINATES, the HELMHOLTZ DIFFERENTIAL EQUATION is not separable, but LAPLACE'S EQUATION is.

See also LAPLACE'S EQUATION–BIPOLAR COORDINATES

Helmholtz Differential Equation—Bispherical Coordinates

The HELMHOLTZ DIFFERENTIAL EQUATION is not separable in BISPHERICAL COORDINATES.

See also BISPHERICAL COORDINATES, HELMHOLTZ DIFFERENTIAL EQUATION, LAPLACE'S EQUATION–BISPHERICAL COORDINATES

Helmholtz Differential Equation—Cartesian Coordinates

In 2-D CARTESIAN COORDINATES, attempt SEPARATION OF VARIABLES by writing

$$F(x, y) = X(x) Y(y), \tag{1}$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2 X}{dx^2} Y + \frac{d^2 Y}{dy^2} X + k^2 XY = 0. \tag{2}$$

Dividing both sides by XY gives

$$\frac{1}{X}\frac{d^2X}{dx^2}+\frac{1}{Y}\frac{d^2Y}{dy^2}+k^2=0. \tag{3}$$

This leads to the two coupled ordinary differential equations with a separation constant m^2,

$$\frac{1}{X}\frac{d^2X}{dx^2}=m^2 \tag{4}$$

$$\frac{1}{Y}\frac{d^2Y}{dy^2}=-(m^2+k^2), \tag{5}$$

where X and Y could be interchanged depending on the boundary conditions. These have solutions

$$X=A_m e^{mx}+B_m e^{-mx} \tag{6}$$

$$Y=C_m e^{i\sqrt{m^2+k^2}y}+D_m e^{-i\sqrt{m^2+k^2}y}$$

$$=E_m \sin(\sqrt{m^2+k^2}y)+F_m \cos(\sqrt{m^2+k^2}y). \tag{7}$$

The general solution is then

$$F(x,\ y)=\sum_{m=1}^{\infty}(A_m e^{mx}+B_m e^{-mx})$$

$$\times[E_m \sin(\sqrt{m^2+k^2}y)+F_m \cos(\sqrt{m^2+k^2}y)]. \tag{8}$$

In 3-D CARTESIAN COORDINATES, attempt SEPARATION OF VARIABLES by writing

$$F(x,\ y,\ z)=X(x)Y(y)Z(z), \tag{9}$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2X}{dx^2}YZ+\frac{d^2Y}{dy^2}XZ+\frac{d^2Z}{dz^2}XY+k^2XY=0. \tag{10}$$

Dividing both sides by XYZ gives

$$\frac{1}{X}\frac{d^2X}{dx^2}+\frac{1}{Y}\frac{d^2Y}{dy^2}+\frac{1}{Z}\frac{d^2Z}{dz^2}+k^2=0. \tag{11}$$

This leads to the three coupled differential equations

$$\frac{1}{X}\frac{d^2X}{dx^2}=t^2 \tag{12}$$

$$\frac{1}{Y}\frac{d^2Y}{dy^2}=m^2 \tag{13}$$

$$\frac{1}{Z}\frac{d^2Z}{dz^2}=(k^2+l^2+m^2), \tag{14}$$

where X, Y, and Z could be permuted depending on boundary conditions. The general solution is therefore

$$F(x,\ y,\ z)=\sum_{l=1}^{\infty}\sum_{m=1}^{\infty}(A_l e^{lx}+B_l e^{-lx})(C_m e^{my}+D_m e^{-my})$$

$$\times(E_{lm}e^{-i\sqrt{k^2+l^2+m^2}z}+F_{lm}e^{i\sqrt{k^2+l^2+m^2}z}). \tag{15}$$

See also CARTESIAN COORDINATES, HELMHOLTZ DIFFERENTIAL EQUATION

References

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I.* New York: McGraw-Hill, pp. 501–02, 513–14 and 656, 1953.

Helmholtz Differential Equation—Circular Cylindrical Coordinates

In CYLINDRICAL COORDINATES, the SCALE FACTORS are $h_r=1$, $h_\theta=r$, $h_z=1$, so the LAPLACIAN is given by

$$\nabla^2F=\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial F}{\partial r}\right)+\frac{1}{r^2}\frac{\partial^2F}{\partial\theta^2}+\frac{\partial^2F}{\partial z^2}. \tag{1}$$

Attempt SEPARATION OF VARIABLES in the HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2F+k^2F=0 \tag{2}$$

by writing

$$F(r,\ \theta,\ z)=R(r)\Theta(\theta)Z(z), \tag{3}$$

then combining (1) and (2) gives

$$\frac{d^2R}{dr^2}\Theta Z+\frac{1}{r}\frac{dR}{dr}\Theta Z+\frac{1}{r^2}\frac{d^2\Theta}{d\theta^2}RZ+\frac{d^2Z}{dz^2}R\Theta+k^2R\Theta Z$$

$$=0. \tag{4}$$

Now multiply by $r^2/(R\Theta Z)$,

$$\left(\frac{r^2}{R}\frac{d^2R}{dr^2}+\frac{r}{R}\frac{dR}{dr}\right)+\frac{1}{\Theta}\frac{d^2\Theta}{d\theta^2}+\frac{r^2}{Z}\frac{d^2Z}{dz^2}+k^2r^2=0, \tag{5}$$

so the equation has been separated. Since the solution must be periodic in θ from the definition of the circular cylindrical coordinate system, the solution to the second part of (5) must have a NEGATIVE separation constant

$$\frac{1}{\Theta}\frac{d^2\theta}{d\theta^2}=-m^2, \tag{6}$$

which has a solution

$$\Theta(\theta)=C_m\cos(m\theta)+D_m\sin(m\theta). \tag{7}$$

Plugging (7) back into (5) gives

$$\frac{r^2}{R}\frac{d^2R}{dr^2}+\frac{r}{R}\frac{dR}{dr}-m^2+\frac{r^2}{Z}\frac{d^2Z}{dz^2}+k^2r^2=0, \tag{8}$$

and dividing through by r^2 results in

$$\frac{1}{R}\frac{d^2R}{dr^2}+\frac{1}{rR}\frac{dR}{dr}-\frac{m^2}{r^2}+\frac{1}{Z}\frac{d^2Z}{dz^2}+k^2=0. \quad (9)$$

The solution to the second part of (9) must not be sinusoidal at $\pm\infty$ for a physical solution, so the differential equation has a POSITIVE separation constant

$$\frac{1}{Z}\frac{d^2Z}{dz^2}=n^2, \quad (10)$$

and the solution is

$$Z(z)=E_n e^{-nx}+F_n e^{nx}. \quad (11)$$

Plugging (11) back into (9) and multiplying through by R yields

$$\frac{d^2R}{dr^2}+\frac{1}{r}\frac{dR}{dr}+\left(n^2+k^2-\frac{m^2}{r^2}\right)R=0 \quad (12)$$

But this is just a modified form of the BESSEL DIFFERENTIAL EQUATION, which has a solution

$$R(r)=A_{mn}J_m(\sqrt{n^2+k^2}r)+B_{mn}Y_m(\sqrt{n^2+k^2}r), \quad (13)$$

where $J_n(x)$ and $Y_n(x)$ are BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS, respectively. The general solution is therefore

$$F(r,\ \theta,\ z)=\sum_{m=o}^{\infty}\sum_{n=0}^{\infty}[A_{mn}J_m(\sqrt{k^2+n^2}r)$$
$$+B_{mn}Y_m(\sqrt{k^2+n^2}r)]$$
$$\times[C_m\cos(m\theta)+D_m\sin(m\theta)](E_n e^{-nz}+F_n e^{nz}). \quad (14)$$

In the notation of Morse and Feshbach (1953), the separation functions are $f_1(r)=r$, $f_2(\theta)=1$, $f_3(z)=1$, so the STÄCKEL DETERMINANT is 1.

The HELMHOLTZ DIFFERENTIAL EQUATION is also separable in the more general case of k^2 OF THE FORM

$$k^2(r,\ \theta,\ z)=f(r)+\frac{g(\theta)}{r^2}+h(z)+k'^2. \quad (15)$$

See also CYLINDRICAL COORDINATES, HELMHOLTZ DIFFERENTIAL EQUATION

Helmholtz Differential Equation—Confocal Ellipsoidal Coordinates

Using the NOTATION of Byerly (1959, pp. 252–53), LAPLACE'S EQUATION can be reduced to

$$\nabla^2F=(\mu^2-\nu^2)\frac{\partial^2F}{\partial\alpha^2}+(\lambda^2-\nu^2)\frac{\partial^2F}{\partial\beta^2}+(\lambda^2-\mu^2)\frac{\partial^2F}{\partial\gamma^2}$$
$$=0, \quad (1)$$

where

$$\alpha=c\int_c^\lambda\frac{d\lambda}{\sqrt{(\lambda^2-b^2)(\lambda^2-c^2)}}$$
$$=F\left(\frac{b}{c},\ \frac{\pi}{2}\right)-F\left(\frac{b}{c},\ \sin^{-1}\left(\frac{c}{\lambda}\right)\right) \quad (2)$$

$$\beta=c\int_b^\mu\frac{d\mu}{\sqrt{(c^2-\mu^2)(\mu^2-b^2)}}$$
$$=F\left(\sqrt{1-b^2-c^2},\ \sin^{-1}\left(\sqrt{\frac{1-\frac{b^2}{\mu^2}}{1-\frac{b^2}{c^2}}}\right)\right) \quad (3)$$

$$\gamma=c\int_0^\nu\frac{d\nu}{\sqrt{(b^2-\nu^2)(c^2-\nu^2)}}$$
$$=F\left(\frac{b}{c},\ \sin^{-1}\left(\frac{\nu}{b}\right)\right). \quad (4)$$

In terms of α, β, and γ,

$$\lambda=c\ \mathrm{dc}\left(\alpha,\ \frac{b}{c}\right) \quad (5)$$

$$\mu=b\ \mathrm{nd}\left(\beta,\ \sqrt{1-\frac{b^2}{c^2}}\right) \quad (6)$$

$$\nu=b\ \mathrm{sn}\left(\gamma,\ \frac{b}{c}\right). \quad (7)$$

Equation (1) is not separable using a function OF THE FORM

$$F=L(\alpha)M(\beta)N(\gamma), \quad (8)$$

but it is if we let

$$\frac{1}{L}\frac{d^2L}{d\alpha^2}=\sum a_k\lambda^k \quad (9)$$

$$\frac{1}{M}\frac{d^2M}{d\beta^2}=\sum b_k\mu^k \quad (10)$$

$$\frac{1}{N}\frac{d^2N}{d\gamma^2}=\sum c_k\nu^k. \quad (11)$$

These give

$$a_0 = -b_0 = c_0 \tag{12}$$

$$a_2 = -b_2 = c_2, \tag{13}$$

and all others terms vanish. Therefore (1) can be broken up into the equations

$$\frac{d^2L}{d\alpha^2} = (a_0 + a_2\lambda^2)L \tag{14}$$

$$\frac{d^2M}{d\beta^2} = -(a_0 + a_2\mu^2)M \tag{15}$$

$$\frac{d^2N}{d\gamma^2} = (a_0 + a_2\nu^2)N. \tag{16}$$

For future convenience, now write

$$a_0 = -(b^2 + c^2)p \tag{17}$$

$$a_2 = m(m+1), \tag{18}$$

then

$$\frac{d^2L}{d\alpha^2} - [m(m+1)\lambda^2 - (b^2+c^2)p]L = 0 \tag{19}$$

$$\frac{d^2M}{d\beta^2} + [m(m+1)\mu^2 - (b^2+c^2)p]M = 0 \tag{20}$$

$$\frac{d^2N}{d\gamma^2} - [m(m+1)\nu^2 - (b^2+c^2)p]N = 0. \tag{21}$$

Now replace α, β, and γ to obtain

$$(\lambda^2 - b^2)(\lambda^2 - c^2)\frac{d^2L}{d\lambda^2} + \lambda(\lambda^2 - b^2 + \lambda^2 - c^2)\frac{dL}{d\lambda}$$

$$-[m(m+1)\lambda^2 - (b^2+c^2)p]L = 0 \tag{22}$$

$$(\mu^2 - b^2)(\mu^2 - c^2)\frac{d^2M}{d\mu^2} + \mu(\mu^2 - b^2 + \mu^2 - c^2)\frac{dM}{d\mu}$$

$$-[m(m+1)\mu^2 - (b^2+c^2)p]M = 0 \tag{23}$$

$$(\nu^2 - b^2)(\nu^2 - c^2)\frac{d^2N}{d\nu^2} + \nu(\nu^2 - b^2 + \nu^2 - c^2)\frac{dN}{d\nu}$$

$$-[m(m+1)\nu^2 - (b^2+c^2)p]N = 0. \tag{24}$$

Each of these is a LAMÉ'S DIFFERENTIAL EQUATION, whose solution is called an ELLIPSOIDAL HARMONIC. Writing

$$L(\lambda) = E_m^p(\lambda) \tag{25}$$

$$M(\lambda) = E_m^p(\mu) \tag{26}$$

$$N(\lambda) = E_m^p(\nu) \tag{27}$$

gives the solution to (1) as a product of ELLIPSOIDAL HARMONICS $E_m^p(x)$.

$$F = E_m^p(\lambda)E_m^p(\mu)E_m^p(\nu). \tag{28}$$

Helmholtz Differential Equation—Confocal Paraboloidal Coordinates

As shown by Morse and Feshbach (1953), the HELMHOLTZ DIFFERENTIAL EQUATION is separable in CONFOCAL PARABOLOIDAL COORDINATES.

See also CONFOCAL PARABOLOIDAL COORDINATES, HELMHOLTZ DIFFERENTIAL EQUATION

References

Moon, P. and Spencer, D. E. *Field Theory Handbook, Including Coordinate Systems, Differential Equations, and Their Solutions, 2nd ed.* New York: Springer-Verlag, pp. 47–8, 1988.

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I.* New York: McGraw-Hill, p. 664, 1953.

Helmholtz Differential Equation—Conical Coordinates

In CONICAL COORDINATES, LAPLACE'S EQUATION can be written

$$\frac{\partial^2 V}{\partial\alpha^2} + \frac{\partial^2 V}{\partial\beta^2} + (\mu^2 - \nu^2)\frac{\partial}{\partial\lambda}\left(\lambda^2 \frac{\partial V}{\partial\lambda}\right) = 0, \tag{1}$$

where

$$\alpha = \int_a^\mu \frac{d\mu}{\sqrt{(\mu^2 - a^2)(b^2 - \mu^2)}} \tag{2}$$

$$\beta = \int_0^\nu \frac{d\nu}{\sqrt{(a^2 - \nu^2)(b^2 - \nu^2)}} \tag{3}$$

(Byerly 1959). Letting

$$V = U(u)R(r) \tag{4}$$

breaks (1) into the two equations,

$$\frac{d}{dr}\left(r^2 \frac{dR}{dr}\right) = m(m+1)R \tag{5}$$

$$\frac{\partial^2 U}{\partial \alpha^2} + \frac{\partial^2 U}{\partial \beta^2} + m(m+1)(\mu^2 - \nu^2)U = 0 \qquad (6)$$

Solving these gives

$$R(r) = Ar^m + Br^{-m-1} \qquad (7)$$

$$U(u) = E_m^p(\mu)E_m^p(\nu), \qquad (8)$$

where E_m^p are ELLIPSOIDAL HARMONICS. The regular solution is therefore

$$V = Ar^m E_m^p(\mu)E_m^p(\nu), \qquad (9)$$

However, because of the cylindrical symmetry, the solution $E_m^p(\mu)E_m^p(\nu)$ is an mth degree SPHERICAL HARMONIC.

Byerly, W. E. *An Elementary Treatise on Fourier's Series, and Spherical, Cylindrical, and Ellipsoidal Harmonics, with Applications to Problems in Mathematical Physics.* New York: Dover, p. 263, 1959.

Moon, P. and Spencer, D. E. *Field Theory Handbook, Including Coordinate Systems, Differential Equations, and Their Solutions, 2nd ed.* New York: Springer-Verlag, pp. 39–0, 1988.

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I.* New York: McGraw-Hill, pp. 514 and 659, 1953.

Helmholtz Differential Equation—Elliptic Cylindrical Coordinates

In ELLIPTIC CYLINDRICAL COORDINATES, the SCALE FACTORS are $h_u = h_v = \sqrt{\sinh^2 u + \sin^2 v}$, $h_z = 1$, and the separation functions are $f_1(u) = f_2(v) = f_3(z) = 1$, giving a STÄCKEL DETERMINANT of $S = (\sin^2 v + \sinh^2 u)$. The Helmholtz differential equation is

$$\frac{1}{\sinh^2 u + \sin^2 v}\left(\frac{\partial^2 F}{\partial u^2} + \frac{\partial^2 F}{\partial v^2}\right) + \frac{\partial^2 F}{\partial z^2} + k^2 F = 0. \qquad (1)$$

Attempt SEPARATION OF VARIABLES by writing

$$F(u, v, z) = U(u)V(v)Z(z), \qquad (2)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{Z}{\sinh^2 u + \sin^2 v}\left(V\frac{d^2U}{du^2} + U\frac{d^2V}{dv^2}\right) + UV\frac{d^2Z}{dz^2} + k^2 UVZ = 0. \qquad (3)$$

Now divide by UVZ to give

$$\frac{1}{\sinh^2 u + \sin^2 v}\left(\frac{1}{U}\frac{\partial^2 U}{\partial u^2} + \frac{1}{V}\frac{\partial^2 V}{\partial v^2}\right) + \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} + k^2 = 0. \qquad (4)$$

Separating the Z part,

$$\frac{1}{Z}\frac{d^2Z}{dz^2} = -(k^2 + m^2) \qquad (5)$$

$$\frac{1}{\sinh^2 u + \sin^2 v}\left(\frac{1}{U}\frac{\partial^2 U}{\partial u^2} + \frac{1}{V}\frac{\partial^2 V}{\partial v^2}\right) = m^2 \qquad (6)$$

so

$$\frac{\partial^2 Z}{dz^2} = -(k^2 + m^2)Z, \qquad (7)$$

which has the solution

$$Z(z) = A_{km}\cos(\sqrt{k^2+m^2}z) + B_{km}\sin(\sqrt{k^2+m^2}z). \qquad (8)$$

Rewriting (6) gives

$$\left(\frac{1}{U}\frac{d^2U}{du^2} - m^2\sinh^2 u\right) + \left(\frac{1}{V}\frac{d^2V}{dv^2} - m^2\sin^2 v\right) = 0, \qquad (9)$$

which can be separated into

$$\frac{1}{U}\frac{d^2U}{du^2} - m^2\sinh^2 u = c \qquad (10)$$

$$c + \frac{1}{V}\frac{d^2V}{dv^2} - m^2\sin^2 v = 0, \qquad (11)$$

so

$$\frac{d^2U}{du^2} - (c + m^2\sinh^2 u)U = 0 \qquad (12)$$

$$\frac{d^2V}{dv^2} + (c - m^2\sin^2 v)V = 0. \qquad (13)$$

Now use

$$\sinh^2 u = \tfrac{1}{2}[\cosh(2u) - 1] \qquad (14)$$

$$\sin^2 v = \tfrac{1}{2}[1 - \cos(2v)] \qquad (15)$$

to obtain

$$\frac{d^2U}{du^2} - \{c + \tfrac{1}{2}m^2[\cosh(2u) - 1]\}U = 0 \qquad (16)$$

$$\frac{d^2V}{dv^2} + \{c - \tfrac{1}{2}m^2[1 - \cos(2v)]\}V = 0. \qquad (17)$$

Regrouping gives

$$\frac{d^2U}{du^2} - [(c - \tfrac{1}{2}m^2) + \tfrac{1}{2}m^2 \cosh(2u)]U = 0 \quad (18)$$

$$\frac{d^2V}{dv^2} + [(c - \tfrac{1}{2}m^2) + \tfrac{1}{2}m^2 \cos(2v)]V = 0. \quad (19)$$

Let $a \equiv c - m^2/2$ and $q \equiv -m^2/4$, then these become

$$\frac{d^2V}{dv^2} + [a - 2q\cos(2v)]V = 0 \quad (20)$$

$$\frac{d^2U}{du^2} - [a - 2q\cosh(2u)]U = 0. \quad (21)$$

Here, (20) is the MATHIEU DIFFERENTIAL EQUATION and (21) is the modified MATHIEU DIFFERENTIAL EQUATION. These solutions are known as MATHIEU FUNCTIONS.

Helmholtz Differential Equation—Parabolic Coordinates

The SCALE FACTORS are $h_u = h_v = \sqrt{u^2+v^2}$, $h_\theta = uv$ and the separation functions are $f_\theta(u) = u$, $f_2(v) = v$, $f_3(\theta) = 1$, given a STÄCKEL DETERMINANT of $S = u^2 + v^2$. The LAPLACIAN is

$$\frac{1}{u^2+v^2}\left(\frac{1}{u}\frac{\partial F}{\partial u} + \frac{\partial^2 F}{\partial u^2} + \frac{1}{v}\frac{\partial F}{\partial v} + \frac{\partial^2 F}{\partial v^2}\right) + \frac{1}{u^2v^2}\frac{\partial^2 F}{\partial \theta^2} + k^2F = 0. \quad (1)$$

Attempt SEPARATION OF VARIABLES by writing

$$F(u, v, \theta) \equiv U(u)V(v)\Theta(\theta), \quad (2)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{1}{u^2+v^2}\left[V\Theta\left(\frac{1}{u}\frac{dU}{du} + \frac{d^2U}{du^2}\right) + U\Theta\left(\frac{1}{v}\frac{dV}{dv} + \frac{d^2V}{dv^2}\right)\right] + \frac{UV}{u^2v^2}\frac{d^2\Theta}{d\theta^2} + k^2UV\Theta = 0. \quad (3)$$

Now multiply through by $u^2v^2/(UV\Theta)$,

$$\frac{u^2v^2}{u^2+v^2}\left[\frac{1}{U}\left(\frac{1}{u}\frac{dU}{du} + \frac{d^2U}{du^2}\right) + \frac{1}{V}\left(\frac{1}{v}\frac{dV}{dv} + \frac{d^2V}{dv^2}\right)\right] + \frac{1}{\Theta}\frac{d^2\Theta}{d\theta^2} + k^2u^2v^2 = 0. \quad (4)$$

Separating the Θ part gives

$$\frac{1}{\Theta}\frac{d^2\theta}{d\theta^2} = -m^2, \quad (5)$$

which has solution

$$\Theta(\theta) = A_m\cos(m\theta) + B_m\sin(m\theta). \quad (6)$$

Plugging (5) back into (4) and multiplying by $(u^2 + v^2)/(u^2v^2)$ gives

$$\left[\frac{1}{U}\left(\frac{1}{u}\frac{dU}{du} + \frac{d^2U}{du^2}\right) + \frac{1}{V}\left(\frac{1}{v}\frac{dV}{dv} + \frac{d^2V}{dv^2}\right)\right] - m^2\frac{u^2+v^2}{u^2v^2} + k^2(u^2+v^2) \quad (7)$$

Rewriting,

$$\left[\frac{1}{U}\left(\frac{1}{u}\frac{dU}{du} + \frac{d^2U}{du^2}\right) + \frac{1}{V}\left(\frac{1}{v}\frac{dV}{dv} + \frac{d^2V}{dv^2}\right)\right] - m^2\left(\frac{1}{v^2} + \frac{1}{u^2}\right) + k^2(u^2+v^2). \quad (8)$$

This can be rearranged into two terms, each containing only u or v,

$$\left[\frac{1}{U}\left(\frac{1}{u}\frac{dU}{du}+\frac{d^2U}{du^2}\right)+k^2u^2-\frac{m^2}{u^2}\right]$$
$$+\left[\frac{1}{V}\left(\frac{1}{v}\frac{dV}{dv}+\frac{d^2V}{dv^2}\right)+k^2v^2-\frac{m^2}{v^2}\right] \qquad (9)$$

and so can be separated by letting the first part equal c and the second equal $-c$, giving

$$\frac{d^2U}{du^2}+\frac{1}{u}\frac{dU}{du}+\left(k^2u^2-\frac{m^2}{u^2}-c\right)U=0 \qquad (10)$$

$$\frac{d^2V}{dv^2}+\frac{1}{v}\frac{dV}{dv}+\left(k^2v^2-\frac{m^2}{v^2}+c\right)V=0. \qquad (11)$$

See also Helmholtz Differential Equation, Parabolic Coordinates

References

Helmholtz Differential Equation—Parabolic Cylindrical Coordinates

In parabolic cylindrical coordinates, the scale factors are $h_u=h_v=\sqrt{u^2+v^2}$, $h_z=1$ and the separation functions are $f_1(u)=f_2(v)=f_3(z)=1$, giving Stäckel determinant of $s=u^2+v^2$. the Helmholtz differential equation is

$$\frac{1}{u^2+v^2}\left(\frac{\partial^2 f}{\partial u^2}+\frac{\partial^2 f}{\partial v^2}\right)+\frac{\partial^2 f}{\partial z^2}+k^2f=0. \qquad (1)$$

attempt separation of variables by writing

$$f(u, v, z)\equiv u(u)v(v)z(z), \qquad (2)$$

then the Helmholtz differential equation becomes

$$\frac{1}{u^2+v^2}\left(VZ\frac{d^2U}{du^2}+UZ\frac{d^2V}{dv^2}\right)+UV\frac{d^2Z}{dz^2}+k^2UVZ$$
$$=0. \qquad (3)$$

Divide by UVZ,

$$\frac{1}{u^2+v^2}\left(\frac{1}{U}\frac{d^2U}{du^2}+\frac{1}{V}\frac{d^2V}{dv^2}\right)+\frac{1}{Z}\frac{d^2Z}{dz^2}+k^2=0. \qquad (4)$$

Separating the Z part,

$$\frac{1}{Z}\frac{d^2Z}{dz^2}=-(k^2+m^2) \qquad (5)$$

$$\frac{1}{u^2+v^2}\left(\frac{1}{U}\frac{d^2U}{du^2}+\frac{1}{V}\frac{d^2V}{dv^2}\right)-k^2=0. \qquad (6)$$

$$\frac{1}{U}\frac{d^2U}{du^2}+\frac{1}{V}\frac{d^2V}{dv^2}-k^2(u^2+v^2)=0, \qquad (7)$$

so

$$\frac{\partial^2 Z}{dz^2}=-(k^2+m^2)Z, \qquad (8)$$

which has solution

$$Z(z)=A\cos(\sqrt{k^2+m^2}z)+B\sin(\sqrt{k^2+m^2}z), \qquad (9)$$

and

$$\left(\frac{1}{U}\frac{d^2U}{du^2}-k^2u^2\right)+\left(\frac{1}{V}\frac{d^2V}{dv^2}-k^2v^2\right)=0. \qquad (10)$$

This can be separated

$$\frac{1}{U}\frac{d^2U}{du^2}-k^2u^2=c \qquad (11)$$

$$\frac{1}{V}\frac{d^2V}{dv^2}-k^2v^2=-c, \qquad (12)$$

so

$$\frac{d^2U}{du^2}-(c+k^2u^2)U=0 \qquad (13)$$

$$\frac{d^2V}{dv^2}-(c+k^2v^2)V=0. \qquad (14)$$

These are the Weber differential equations, and the solutions are known as Parabolic Cylinder Functions.

See also Helmholtz Differential Equation, Parabolic Cylinder Function, Parabolic Cylindrical Coordinates, Weber Differential Equations

References

Moon, P. and Spencer, D. E. *Field Theory Handbook, Including Coordinate Systems, Differential Equations, and Their Solutions, 2nd ed.* New York: Springer-Verlag, p. 36, 1988.

Helmholtz Differential Equation—Polar Coordinates

In 2-D polar coordinates, attempt separation of variables by writing

$$F(r, \theta)=R(r)\Theta(\theta), \qquad (1)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2R}{dr^2}\Theta+\frac{1}{r}\frac{dR}{dr}\Theta+\frac{1}{r^2}\frac{d^2\Theta}{d\theta^2}R+k^2R\Theta=0. \qquad (2)$$

Divide both sides by $R\Theta$

$$\left(\frac{r^2}{R}\frac{d^2R}{dr^2}+\frac{r}{R}\frac{dR}{dr}\right)+\left(\frac{1}{\Theta}\frac{d^2\Theta}{d\theta^2}+k^2\right)=0. \qquad (3)$$

The solution to the second part of (3) must be periodic, so the differential equation is

$$\frac{d^2\Theta}{d\theta^2}\frac{1}{\Theta}=-(k^2+m^2), \qquad (4)$$

which has solutions

$$\Theta(\theta)=c_1e^{i\sqrt{k^2+m^2}\,\theta}+c_2e^{-i\sqrt{k^2+m^2}\,\theta}$$
$$=c_3\sin(\sqrt{k^2+m^2}\theta)+c_4\cos(\sqrt{k^2+m^2}\theta). \qquad (5)$$

Plug (4) back into (3)

$$r^2R''+rR'-m^2R=0. \qquad (6)$$

This is an EULER DIFFERENTIAL EQUATION with $\alpha\equiv 1$ and $\beta\equiv -m^2$. The roots are $r=\pm m$. So for $m=0$, $r=0$ and the solution is

$$R(r)=c_1+c_2\,\mathrm{In}\,r. \qquad (7)$$

But since In r blows up at $r=0$, the only possible physical solution is $R(r)=c_1$. When $m>0$, $r=\pm m$, so

$$R(r)=c_1r^m+c_2r^{-m}. \qquad (8)$$

But since r^{-m} blows up at $r=0$, the only possible physical solution is $R_m(r)=c_1r^m$. The solution for R is then

$$R_m(r)=c_mr^m \qquad (9)$$

for $m=0$, 1, ...and the general solution is

$$F(r,\ \theta)=\sum_{m=0}^{\infty}[a_mr^m\sin(\sqrt{k^2+m^2}\theta)$$
$$+b_mr^m\cos(\sqrt{k^2+m^2}\theta)]. \qquad (10)$$

Helmholtz Differential Equation—Spherical Coordinates

In SPHERICAL COORDINATES, the SCALE FACTORS are $h_r=1$, $h_\theta=r\sin\phi$, $h_\phi=r$, and the separation functions are $f_1(r)=r^2$, $f_2(\theta)=1$, $f_3(\phi)=\sin\phi$, giving a STÄCKEL DETERMINANT of $S=1$. The LAPLACIAN is

$$\nabla^2\equiv\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{1}{r^2\sin^2\phi}\frac{\partial^2}{\partial\theta^2}+\frac{1}{r^2\sin\phi}\frac{\partial}{\partial\phi}$$
$$\times\left(\sin\phi\frac{\partial}{\partial\phi}\right). \qquad (1)$$

To solve the HELMHOLTZ DIFFERENTIAL EQUATION in SPHERICAL COORDINATES, attempt SEPARATION OF VARIABLES by writing

$$F(r,\ \theta,\ \phi)=R(r)\Theta(\theta)\Phi(\phi). \qquad (2)$$

Then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2R}{dr^2}\Phi\Theta+\frac{2}{r}\frac{dR}{dr}\Phi\Theta+\frac{1}{r^2\sin^2\phi}\frac{d^2\Theta}{d\theta^2}\Phi R$$
$$+\frac{\cos\phi}{r^2\sin\phi}\frac{d\Phi}{d\phi}\Theta R+\frac{1}{r^2}\frac{d^2\Phi}{d\phi^2}\Theta R$$
$$=0. \qquad (3)$$

Now divide by $R\Theta\Phi$,

$$\frac{r^2\sin^2\phi}{\Phi R\Theta}\Phi\Theta\frac{d^2R}{dr^2}+\frac{2}{r}\frac{r^2\sin^2\phi}{\Phi R\Theta}\Phi\Theta\frac{dR}{dr}$$
$$+\frac{1}{r^2\sin^2\phi}\frac{r^2\sin^2\phi}{\Phi R\Theta}\Phi R\frac{d^2\Theta}{d\theta^2}$$
$$+\frac{\cos\phi}{r^2\sin\phi}\frac{r^2\sin^2\phi}{\Phi\Theta R}\frac{d\Phi}{d\phi}\Theta R$$
$$+\frac{1}{r^2}\frac{r^2\sin^2\phi}{\Phi R\Theta}\frac{d^2\Phi}{d\phi^2}\Theta R=0 \qquad (4)$$

$$\left(\frac{r^2 \sin^2\phi}{R}\frac{d^2R}{dr^2}+\frac{2r\sin^2\phi}{R}\frac{dR}{dr}\right)+\left(\frac{1}{\Theta}\frac{d^2\Theta}{d\theta^2}\right)$$
$$+\left(\frac{\cos\phi\sin\phi}{\Phi}\frac{d\Phi}{d\phi}+\frac{\sin^2\phi}{\Phi}\frac{d^2\Phi}{d\phi^2}\right)=0. \tag{5}$$

The solution to the second part of (5) must be sinusoidal, so the differential equation is

$$\frac{d^2\Theta}{d\theta^2}\frac{1}{\Theta}=-m^2, \tag{6}$$

which has solutions which may be defined either as a COMPLEX function with $m=-\infty, ..., \infty$

$$\Theta(\theta)=A_m e^{im\theta}, \tag{7}$$

or as a sum of REAL sine and cosine functions with $m=-\infty, ..., \infty$

$$\Theta(\theta)=S_m \sin(m\theta)+C_m \cos(m\theta). \tag{8}$$

Plugging (6) back into (7),

$$\frac{r^2}{R}\frac{d^2R}{dr^2}+\frac{2r}{R}\frac{dR}{dr}-\frac{1}{\sin^2\phi}\left(m^2+\frac{\cos\phi\sin\phi}{\Phi}\right)\frac{d\Phi}{d\phi}$$
$$+\frac{\sin^2\phi}{\Phi}\frac{d^2\Phi}{d\phi^2}$$
$$=0. \tag{9}$$

The radial part must be equal to a constant

$$\frac{r^2}{R}\frac{d^2R}{dr^2}+\frac{2r}{R}\frac{dR}{dr}=l(l+1) \tag{10}$$

$$r^2\frac{d^2R}{dr^2}+2r\frac{dR}{dr}=l(l+1)R. \tag{11}$$

But this is the EULER DIFFERENTIAL EQUATION, so we try a series solution OF THE FORM

$$R=\sum_{n=0}^{\infty} a_n r^{n+c} \tag{12}$$

Then

$$r^2\sum_{n=0}^{\infty}(n+c)(n+c-1)a_n r^{n+c-2}$$
$$+2r\sum_{n=0}^{\infty}(n+c)a_n r^{n+c-1}$$
$$-l(l+1)\sum_{n=0}^{\infty}a_n r^{n+c}=0 \tag{13}$$

$$\sum_{n=0}^{\infty}(n+c)(n+c-1)a_n r^{n+c}+2\sum_{n=0}^{\infty}(n+c)a_n r^{n+c}$$
$$-l(l+1)\sum_{n=0}^{\infty}a_n r^{n+c}=0 \tag{14}$$

$$\sum_{n=0}^{\infty}[(n+c)(n+c-1)-l(l+1)]a_n r^{n+c}=0. \tag{15}$$

This must hold true for all POWERS of r. For the r^c term (with $n = 0$),

$$c(c+1)=l(l+1), \tag{16}$$

which is true only if $c=l, -l-1$ and all other terms vanish. So $a_n=0$ for $n \neq l, -l-1$. Therefore, the solution of the R component is given by

$$R_l(r)=A_l r^l+B_l r^{-l-1}. \tag{17}$$

Plugging (17) back into (9),

$$l(l+1)-\frac{m^2}{\sin^2\phi}+\frac{\cos\phi}{\sin\phi}\frac{1}{\Phi}\frac{d\Phi}{d\phi}+\frac{1}{\Phi}\frac{d^2\Phi}{d\phi^2}=0 \tag{18}$$

$$\Phi''\frac{\cos\phi}{\sin\phi}\Phi'+\left[l(l+1)-\frac{m^2}{\sin^2\phi}\right]\Phi=0, \tag{19}$$

which is the associated LEGENDRE DIFFERENTIAL EQUATION for $x=\cos\phi$ and $m=0, ..., l$. The general COMPLEX solution is therefore

$$\sum_{t=0}^{\infty}\sum_{m=-l}^{l}(A_l r^l+B_l r^{-l-1})P_l^m(\cos\phi)e^{-im\theta}$$
$$\equiv\sum_{t=0}^{\infty}\sum_{m=-1}^{l}(A_l r^l+B_l r^{-l-1})Y_l^m(\theta,\ \phi) \tag{20}$$

where

$$Y_l^m(\theta,\ \phi)\equiv P_l^m(\cos\phi)e^{-im\theta} \tag{21}$$

are the (COMPLEX) SPHERICAL HARMONICS. The general REAL solution is

$$\sum_{t=0}^{\infty}\sum_{m=0}^{l}(A_l r^l+B_l r^{-l-1})P_l^m(\cos\phi)$$
$$\times[S_m\sin(m\theta)+C_m\cos(m\theta)]. \tag{22}$$

Some of the normalization constants of P_l^m can be absorbed by S_m and C_m, so this equation may appear in the form

$$\sum_{t=0}^{\infty}\sum_{m=0}^{l}(A_l r^l+B_l r^{-l-1})P_l^m(\cos\phi)$$
$$\times[S_l^m\sin(m\theta)+C_l^m\cos(m\theta)]$$
$$\equiv\sum_{l=0}^{\infty}\sum_{m=0}^{l}(A_l r^l+B_l r^{-l-1})$$
$$\times[S_l^m Y_l^{m(o)}(\theta,\ \phi)+C_l^m Y_l^{m(e)}(\theta,\ \phi)], \tag{23}$$

where

$$Y_l^{m(0)}(\theta,\ \phi)\equiv P_l^m(\cos\theta)\sin(m\theta) \tag{24}$$

$$Y_l^{m(e)}(\theta,\ \phi)\equiv P_l^m(\cos\theta)\cos(m\theta) \tag{25}$$

are the EVEN and ODD (real) SPHERICAL HARMONICS. If azimuthal symmetry is present, then $\Theta(\theta)$ is constant and the solution of the Φ component is a LEGENDRE POLYNOMIAL $P_l(\cos\phi)$. The general solution is then

$$F(r, \phi) = \sum_{l=0}^{\infty} (A_l r^l B_l r^{-l-1}) P_l(\cos\phi). \tag{26}$$

Actually, the equation is separable under the more general condition that k^2 is OF THE FORM

$$k^2(r, \theta, \phi) = f(r) + \frac{g(\theta)}{r^2} + \frac{h(\phi)}{r^2 \sin\theta} + k'^2. \tag{27}$$

See also HELMHOLTZ DIFFERENTIAL EQUATION, SPHERICAL COORDINATES, SPHERICAL HARMONIC

Helmholtz Differential Equation—Spherical Surface

On the surface of a SPHERE, attempt SEPARATION OF VARIABLES in SPHERICAL COORDINATES by writing

$$F(\theta, \phi) = \Theta(\theta)\Phi(\phi), \tag{1}$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{1}{\sin^2\phi}\frac{d^2\Theta}{d\theta^2}\Phi + \frac{\cos\phi}{\sin\phi}\frac{d\Phi}{d\phi}\Theta + \frac{d^2\Phi}{d\phi^2}\Theta + k^2\Theta\Phi = 0. \tag{2}$$

Dividing both sides by $\Phi\Theta$,

$$\left(\frac{\cos\phi\sin\phi}{\Phi}\frac{d\Phi}{d\phi} + \frac{\sin^2\phi}{\Phi}\frac{d^2\Phi}{d\phi^2}\right) + \left(\frac{1}{\Theta}\frac{d^2\Theta}{d\theta^2} + k^2\right) = 0, \tag{3}$$

which can now be separated by writing

$$\frac{d^2\Theta}{d\theta^2}\frac{1}{\Theta} = -(k^2 + m^2). \tag{4}$$

The solution to this equation must be periodic, so m must be an INTEGER. The solution may then be defined either as a COMPLEX function

$$\Theta(\theta) = A_m e^{i\sqrt{k^2+m^2}\,\theta} + B_m e^{-i\sqrt{k^2+m^2}\,\theta} \tag{5}$$

for $m = -\infty, \ldots, \infty$, or as a sum of REAL sine and cosine functions

$$\Theta(\theta) = S_m \sin\left(\sqrt{k^2+m^2}\,\theta\right) + C_m \cos\left(\sqrt{k^2+m^2}\,\theta\right) \tag{6}$$

for $m = 0, \ldots, \infty$. Plugging (4) into (3) gives

$$\frac{\cos\phi\sin\phi}{\Phi}\frac{d\Phi}{d\phi} + \frac{\sin^2\phi}{\Phi}\frac{d^2\Phi}{d\phi^2} + m^2 = 0 \tag{7}$$

$$\Phi'' + \frac{\cos\phi}{\sin\phi}\Phi' + \frac{m^2}{\sin^2\phi}\Phi = 0, \tag{8}$$

which is the LEGENDRE DIFFERENTIAL EQUATION for $x = \cos\phi$ with

$$m^2 \equiv l(l+1), \tag{9}$$

giving

$$l^2 + l - m^2 = 0 \tag{10}$$

$$l = \tfrac{1}{2}(-1 \pm \sqrt{1+4m^2}). \tag{11}$$

Solutions are therefore LEGENDRE POLYNOMIALS with a COMPLEX index. The general COMPLEX solution is then

$$F(\theta, \phi) = \sum_{m=-\infty}^{\infty} P_l(\cos\phi)(A_m e^{im\theta} + B_m e^{-im\theta}), \tag{12}$$

and the general REAL solution is

$$F(\theta, \phi) = \sum_{m=0}^{\infty} P_l(\cos\phi) \times [S_m \sin(m\theta) + C_m \cos(m\theta)]. \tag{13}$$

Note that these solutions depend on only a single variable m. However, on the surface of a sphere, it is usual to express solutions in terms of the SPHERICAL HARMONICS derived for the 3-D spherical case, which depend on the two variables l and m.

Helmholtz Differential Equation—Toroidal Coordinates

The HELMHOLTZ DIFFERENTIAL EQUATION is not separable in TOROIDAL COORDINATES

See also HELMHOLTZ DIFFERENTIAL EQUATION, LAPLACE'S EQUATION–TOROIDAL COORDINATES, TOROIDAL COORDINATES

Helmholtz's Theorem

Any VECTOR FIELD $\mathbf{v}$ satisfying

$$[\nabla \cdot \mathbf{v}]_\infty = 0 \tag{1}$$

$$[\nabla \times \mathbf{v}]_\infty = 0 \tag{2}$$

may be written as the sum of an IRROTATIONAL part

and a SOLENOIDAL part,

$$\mathbf{v} = -\nabla\phi + \nabla \times \mathbf{A}, \qquad (3)$$

where for a VECTOR FIELD F,

$$\phi = -\int_V \frac{\nabla \cdot \mathbf{F}}{4\pi|\mathbf{r}' - \mathbf{r}|} d^3\mathbf{r}' \qquad (4)$$

$$\mathbf{A} = \int_V \frac{\nabla \times \mathbf{F}}{4\pi|\mathbf{r}' - \mathbf{r}|} d^3\mathbf{r}'. \qquad (5)$$

Helson-Szego Measure

An absolutely continuous measure on ∂D whose density has the form $\exp(x + \tilde{y})$, where x and y are real-valued functions in L^∞, $\|y\|_\infty < \pi/2$, exp is the EXPONENTIAL FUNCTION, and $\|y\|$ is the NORM.

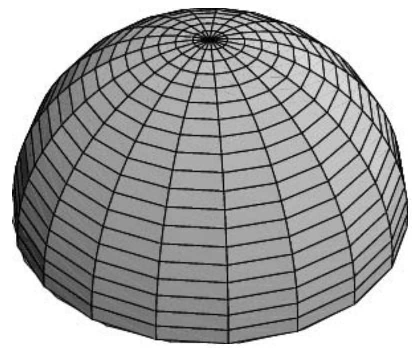
Hemicylindrical Function

A function $S_n(z)$ which satisfies the RECURRENCE RELATION

$$S_{n-1}(z) - S_{n+1}(z) = 2S_n'(z)$$

together with

$$S_1(z) = -S_0'(z)$$



is called a hemicylindrical function.

Hemisphere

Half of a SPHERE cut by a PLANE passing through its CENTER. A hemisphere of RADIUS r can be given by the usual SPHERICAL COORDINATES

$$x = r\cos\theta\sin\phi \qquad (1)$$

$$y = r\sin\theta\sin\phi \qquad (2)$$

$$z = r\cos\phi, \qquad (3)$$

where $\theta \in [0, 2\pi)$ and $\phi \in [0, \pi/2]$. All CROSS SECTIONS passing through the z-AXIS are SEMICIRCLES.

The VOLUME of the hemisphere is

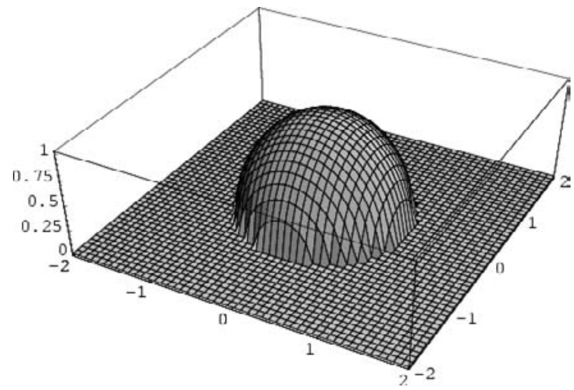
$$V = \pi\int_0^r (r^2 - z^2)\,dz = \tfrac{2}{3}\pi r^3. \qquad (4)$$

The weighted mean of z over the hemisphere is

$$\langle z\rangle = \pi\int_0^r z(r^2 - z^2)\,dz = \tfrac{1}{4}\pi r^2. \qquad (5)$$

The CENTROID is then given by

$$\bar{z} = \frac{\langle z\rangle}{V} = \tfrac{3}{8} r \qquad (6)$$



(Beyer 1987).

Hemispherical Function

The hemisphere function is defined as

$$H(x, y) = \begin{cases} \sqrt{a - x^2 - y^2} & \text{for } \sqrt{x^2 + y^2} \le a \\ 0 & \text{for } \sqrt{x^2 + y^2} > a. \end{cases}$$

Watson (1966) defines a hemispherical function as a function S which satisfies the RECURRENCE RELATIONS

$$S_{n-1}(z) - S_{n+1}(z) = 2S'_n(z)$$

with

$$S_1(z) = -S'_0(z)$$

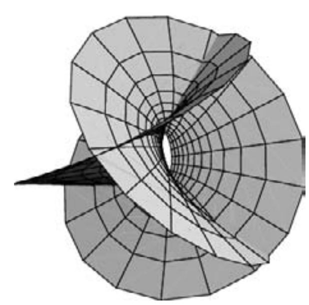
Hendecagon



An 11-sided polygon, also variously known as the undecagon or unidecagon. The term "hendecagon" is preferable to the other two since it uses the Greek prefix and suffix instead of mixing a Roman prefix and Greek suffix. The regular 11-sided POLYGON has SCHLÄFLI SYMBOL $\{11\}$.
The hendecagon cannot be constructed using the classical Greek rules of GEOMETRIC CONSTRUCTION, but Conway and Guy (1996) give a NEUSIS CONSTRUCTION based on TRISECTION.

Henneberg's Minimal Surface

A MINIMAL SURFACE and double ALGEBRAIC SURFACE of 15th order and fifth class which can be given by PARAMETRIC EQUATIONS

$$x(u, v) = 2 \sinh u \cos v - \tfrac{2}{3} \sinh(3u) \cos(3v) \quad (1)$$

$$y(u, v) = 2 \sinh u \sin v + \tfrac{2}{3} \sinh(3u) \sin(3v) \quad (2)$$

$$z(u, v) = 2 \cosh(2u) \cos(2v). \quad (3)$$

The coefficients of the FIRST FUNDAMENTAL FORM of this parameterization are given by

$$E = 8 \cosh^2 u [\cosh(4u) - \cos(4v)] \quad (4)$$

$$F = 0 \quad (5)$$

$$G = 8\cosh^2 u[\cosh(4u) - \cos(4v)], \quad (6)$$

and the coefficients of the SECOND FUNDAMENTAL FORM are

$$e = -4\cos(2v)\sinh(2u) \quad (7)$$

$$f = 4\cosh(2u)\sin(2v) \quad (8)$$

$$g = 4\sinh(2u)\cos(2v), \quad (9)$$

giving AREA ELEMENT

$$dS = 2\sqrt{2[\cos(4v) - \cosh(4u)]} \quad (10)$$

and GAUSSIAN and MEAN CURVATURES are

$$K = \frac{\operatorname{sech}^4 u}{8[\cos(4v) - \cosh(4u)]} \quad (11)$$

$$H = 0. \quad (12)$$

The surface can also be obtained from the ENNEPER-WEIERSTRASS PARAMETERIZATION with

$$f = 2 - 2z^{-4} \quad (13)$$

$$g = z, \quad (14)$$

which gives a parameterization OF THE FORM

$$x = \frac{2(r^2 - 1)\cos\phi}{r} - \frac{2(r^6 - 1)\cos(3\phi)}{3r^3} \quad (15)$$

$$y = -\frac{6r^2(r^2 - 1)\sin\phi + 2(r^6 - 1)\sin(3\phi)}{3r^3} \quad (16)$$

$$z = \frac{2(r^4 + 1)\cos(2\phi)}{r^2} \quad (17)$$

Henneberg's minimal surface is a NONORIENTABLE SURFACE defined over the UNIT DISK. It is an immersion of the REAL PROJECTIVE PLANE that has been multiply PUNCTURED (once at the origin and four times at each of the roots of the metric). Consequently, it is not a COMPLETE SURFACE. The total curvature is -2π.

Hénon Attractor

HÉNON MAP

Hénon Map

A quadratic 2-D MAP given by the equations

$$x_{n+1} = 1 - \alpha x_n^2 + y_n \quad (1)$$

$$y_{n+1} = \beta x_n \quad (2)$$

or

$$x_{n+1} = x_n \cos\alpha - (y_n - x_n^2)\sin\alpha \quad (3)$$

$$y_{n+1} = x_n \sin\alpha + (y_n - x_n^2)\cos\alpha. \quad (4)$$

The above map is for $\alpha = 1.4$ and $\beta = 0.3$. The Hénon map has CORRELATION EXPONENT 1.25 ± 0.02 (Grassberger and Procaccia 1983) and CAPACITY DIMENSION 1.261 ± 0.003 (Russell *et al.* 1980). Hitzl and Zele (1985) give conditions for the existence of periods 1 to 6.

Hénon-Heiles Equation

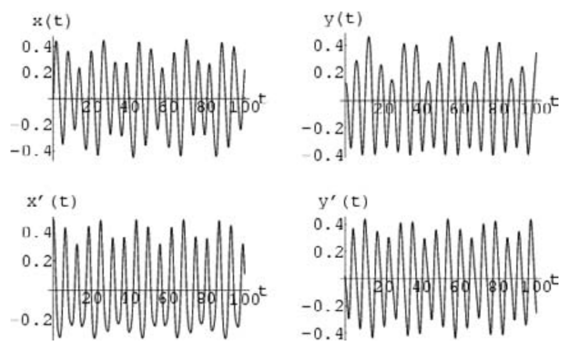
A nonlinear *nonintegrable* HAMILTONIAN SYSTEM with

$$\ddot{x} = -\frac{\partial V}{\partial x} \quad (1)$$

$$\ddot{y} = -\frac{\partial V}{\partial y}, \quad (2)$$

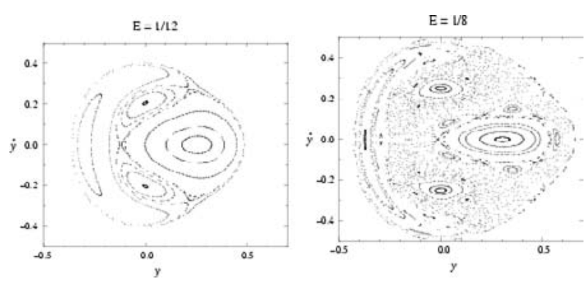
where the potential energy function is defined by the polar equation

$$V(r, \theta) = \tfrac{1}{2} r^2 + \tfrac{1}{3} r^3 \sin(3\theta), \quad (3)$$



giving Cartesian potential

$$V(x, y) = \tfrac{1}{2}\left(x^2 + y^2 + 2x^2 y - \tfrac{2}{3} y^3\right). \quad (4)$$



The total energy of the system is then given by

$$E = V(x, y) + \tfrac{1}{2}(\dot{x}^2 + \dot{y}^2), \quad (5)$$

which is conserved during motion.

Integrating the above coupled ordinary differential equations from an arbitrary starting point with $x(t=0)=0$ and $E=1/8$ gives the motion illustrated above. Computing the values of t at which $x=0$ and plotting $y(t)$ vs. $\dot{y}(t)$ at these values gives a so-called SURFACE OF SECTION. The surfaces of section shown below correspond to $E=1/12$ and $E=1/8$.

The Hamiltonian for a generalized Hénon-Heiles potential is

$$H = \tfrac{1}{2}(p_x^2 + p_y^2 + Ax^2 + By^2) + Dx^2 y - \tfrac{1}{3} C y^3. \quad (6)$$

The equations of motion are integrable only for

1. $D/C = 0$,
2. $D/C = -1$, $A/B = 1$,
3. $D/C = -1/6$, and
4. $D/C = -1/16$, $A/B = 1/6$.

Henry VIII Prime

TRUNCATABLE PRIME

Hensel's Lemma

An important result in VALUATION THEORY which gives information on finding roots of POLYNOMIALS. Hensel's lemma is formally stated as follow. Let $(K, |\cdot|)$ be a complete NON-ARCHIMEDEAN FIELD, and let R be the corresponding VALUATION RING. Let $f(x)$ be a POLYNOMIAL whose COEFFICIENTS are in R and suppose a_0 satisfies

$$|f(a_0)| < |f'(a_0)|^2, \quad (1)$$

where f' is the (formal) DERIVATIVE of f. Then there exists a unique element $a \in R$ such that $f(a)=0$ and

$$|a - a_0| \le \left|\frac{f(a_0)}{f'(a_0)}\right|. \quad (2)$$

Less formally, if $f(x)$ is a POLYNOMIAL with "INTEGER" COEFFICIENTS and $f(a_0)$ is "small" compared to $f'(a_0)$, then the equation $f(x)=0$ has a solution "near" a_0. In addition, there are no other solutions near a_0, although there may be other solutions. The proof of the LEMMA is based around the Newton-Raphson method and relies on the non-Archimedean nature of the valuation.

Consider the following example in which Hensel's lemma is used to determine that the equation $x^2 = -1$ is solvable in the 5-adic numbers $\mathbb{Q}_5$ (and so we can embed the GAUSSIAN INTEGERS inside $\mathbb{Q}_5$ in a nice way). Let K be the 5-adic numbers $\mathbb{Q}_5$, let $f(x) = x^2 + 1$, and let $a_0 = 2$. Then we have $f(2) = 5$ and $f'(2) = 4$, so

$$|f(2)|_5 = \tfrac{1}{5} < |f'(2)|_5^2 = 1, \quad (3)$$

and the condition is satisfied. Hensel's lemma then tells us that there is a 5-adic number a such that $a^2 + 1 = 0$ and

$$|a - 2|_5 <= \left|\tfrac{5}{4}\right|_5 = \tfrac{1}{5}. \quad (4)$$

Similarly, there is a 5-adic number b such that $b^2 + 1 = 0$ and

$$|b - 3|_5 <= \left|\tfrac{10}{7}\right|_5 = \tfrac{1}{5}. \quad (5)$$

Therefore, we have found both the square roots of -1 in $\mathbb{Q}_5$. It is possible to find the roots of any POLYNOMIAL using this technique.

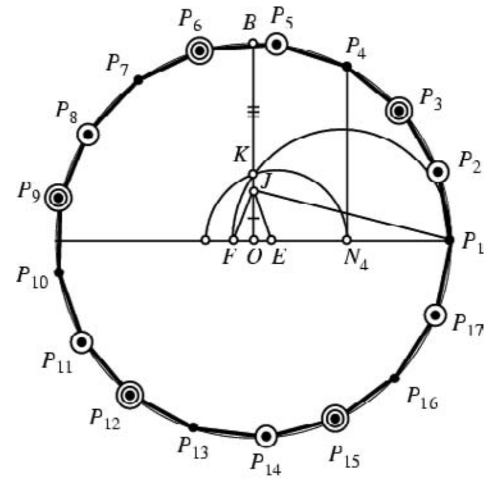
Henstock-Kurzweil Integral

HK INTEGRAL

Heptacontagon

A 70-sided POLYGON.



Heptadecagon

The REGULAR POLYGON of 17 sides is called the HEPTADECAGON, or sometimes the HEPTAKAIDECAGON. Gauss proved in 1796 (when he was 19 years old) that the heptadecagon is CONSTRUCTIBLE with a COMPASS and STRAIGHTEDGE. Gauss's proof appears in his monumental work *Disquisitiones Arithmeticae.* The proof relies on the property of irreducible POLYNOMIAL equations that ROOTS composed of a finite number of SQUARE ROOT extractions only exist when the order of the equation is a product OF THE FORM $2^a 3^b F_c \cdot F_d \cdots F_e$, where the F_n are distinct PRIMES OF THE FORM

$$F_n = 2^{2n} + 1,$$

known as FERMAT PRIMES. Constructions for the regular TRIANGLE (3^1), SQUARE (2^2), PENTAGON ($2^{2^1} + 1$), HEXAGON ($2^1 3^1$), etc., had been given by Euclid, but constructions based on the FERMAT PRIMES ≥ 17 were unknown to the ancients. The first explicit construction of a heptadecagon was given by Erchinger in about 1800.

17-gon construction

The following elegant construction for the heptadecagon (Yates 1949, Coxeter 1969, Stewart 1977, Wells 1992) was first given by Richmond (1893).

1. Given an arbitrary point O, draw a CIRCLE centered on O and a DIAMETER drawn through O.
2. Call the right end of the DIAMETER dividing the CIRCLE into a SEMICIRCLE P_1.
3. Construct the DIAMETER PERPENDICULAR to the original DIAMETER by finding the PERPENDICULAR BISECTOR OB.
4. Construct J a QUARTER the way up OB.
5. Join JP_1 and find E so that $\angle OJE$ is a QUARTER of $\angle OJP_1$.
6. Find F so that $\angle EJF$ is 45°.
7. Construct the SEMICIRCLE with DIAMETER FP_1.
8. This SEMICIRCLE cuts OB at K.
9. Draw a SEMICIRCLE with center E and RADIUS EK.
10. This cuts the extension of OP_1 at N_4.
11. Construct a line PERPENDICULAR to OP_1 through N_4.
12. This line meets the original SEMICIRCLE at P_4.
13. You now have points P_1 and P_4 of a heptadecagon.
14. Use P_1 and P_4 to get the remaining 15 points of the heptadecagon around the original CIRCLE by constructing $P_1, P_4, P_7, P_{10}, P_{13}, P_{16}$ [filled circles], $P_2, P_5, P_8, P_{11}, P_{14}, P_{17}$ [single-ringed filled circles], P_3, P_6, P_9, P_{12}, and P_{15} [double-ringed filled circles].
15. Connect the adjacent points P_i for $i = 1$ to 17, forming the heptadecagon.

This construction, when suitably streamlined, has SIMPLICITY 53. The construction of Smith (1920) has a greater SIMPLICITY of 58. Another construction due to

Tietze (1965) and reproduced in Hall (1970) has a SIMPLICITY of 50. However, neither Tietze (1965) nor Hall (1970) provides a proof that this construction is correct. Both Richmond's and Tietze's constructions require extensive calculations to prove their validity. De Temple (1991) gives an elegant construction involving the CARLYLE CIRCLES which has GEOMETROGRAPHY symbol $8S_1 + 4S_2 + 22C_1 + 11C_3$ and SIMPLICITY 45. The construction problem has now been automated to some extent (Bishop 1978).

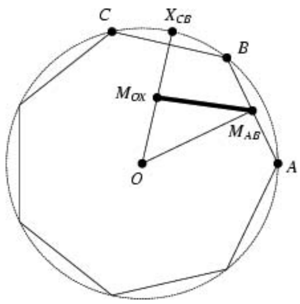
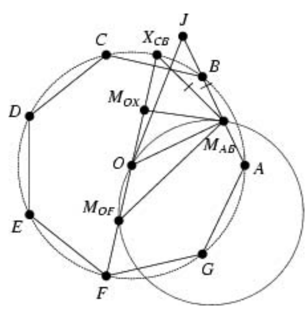
Heptagon

The regular seven-sided POLYGON, illustrated above, which has SCHLÄFLI SYMBOL $\{7\}$. According to Bankoff and Garfunkel (1973), "since the earliest days of recorded mathematics, the regular heptagon has been virtually relegated to limbo." Nevertheless, Thébault (1913) discovered many beautiful properties of the heptagon, some of which are discussed by Bankoff and Garfunkel (1973).



Neusis construction matchstick construction

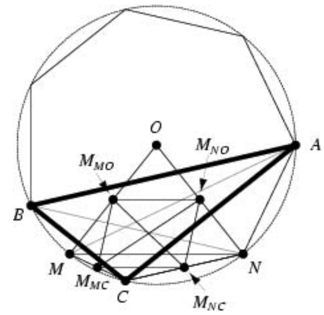


Although the regular heptagon is not a CONSTRUCTIBLE POLYGON using the classical rules of Greek GEOMETRIC CONSTRUCTION, it *is* constructible using a NEUSIS CONSTRUCTION (Johnson 1975; left figure above). To implement the construction, place a mark X on a ruler AZ, and then build a SQUARE of side length AX. Then construct the perpendicular bisector at M to BC, and draw an arc centered at C of radius CE. Now place the marked ruler so that it passes through B, X lies on the arc, and A falls on the perpendicular bisector. Then $2\theta = \angle BAC = \pi/7$, and two such triangles give the vertex angle $2\pi/7$ of a regular heptagon. Conway and Guy (1996) give a NEUSIS CONSTRUCTION for the heptagon. In addition, the regular heptagon can be constructed using seven identical toothpicks to form 1:3:3 triangles (Finlay 1959, Johnson 1975, Wells 1991; right figure above). Bankoff and Garfunkel (1973) discuss the heptagon, including a purported discovery of the NEUSIS CONSTRUCTION by Archimedes (Heath 1931). Madachy (1979) illustrates how to construct a heptagon by folding and knotting a strip of paper, and the regular

heptagon can also be constructed using a CONCHOID OF NICOMEDES.

Although the regular heptagon not constructible using classical techniques, Dixon (1991) gives constructions for several angles very close to $360^\circ/7$. While the ANGLE subtended by a side is $360^\circ/7 \approx 51.428571^\circ$, Dixon gives constructions containing angles of $2\sin^{-1}(\sqrt{3}/4) \approx 51.3178813^\circ$, $\tan^{-1}(5/4) \approx 51.340192^\circ$, and $30^\circ + \sin^{-1}\left(\left(\sqrt{3}-1\right)/2\right) \approx 51.470701^\circ$.

In the regular heptagon with unit CIRCUMRADIUS and center O, construct the MIDPOINT M_{AB} of AB and the MID-ARC POINT X_{CB} of the arc CB, and let M_{OX} be the MIDPOINT of OX_{CB}. Then $M_{OX} = M_{AB} = 1/\sqrt{2}$ (Bankoff and Garfunkel 1973).



In the regular heptagon, construct the points X_{CB}, M_{AB}, and M_{OX} as above. Also construct the midpoint M_{OX} and construct J along the extension of $M_{AB}B$ such that $M_{AB}J = M_{AB}X_{CB}$. Note that the APOTHEM OM_{AB} of the heptagon has length $r = \cos(\pi/7)$. Then

1. The length $x = M_{AB}M_{OF}$ is equal to $\sqrt{2}r = \sqrt{2}\cos(\pi/7)$, and also to the largest root of

$$8x^6 - 20x^4 + 12x^2 - 1 = 0,$$

2. $M_{OJ} = \sqrt{6}/2$, and
3. $M_{AB}M_{OX}$ is tangent to the CIRCUMCIRCLE of $\Delta M_{OF}OM_{AB}$

(Bankoff and Garfunkel 1973).

Construct a HEPTAGONAL TRIANGLE ΔABC in a regular heptagon with center O, and let BN and AM bisect $\angle ABC$ and $\angle BAC$, respectively, with M and N both lying on the circumcircle. Also define the midpoints M_{MO}, M_{NO}, M_{MC}, and M_{NC}. Then

$$MN = \tfrac{1}{2} M_{MO}M_{NO} = \tfrac{1}{2} M_{MC}M_{NC} \tag{1}$$

$$= \sqrt{2} M_{NO}M_{MC} \tag{2}$$

$$M_{MO}M_{MC} = M_{NO}M_{NC} = \tfrac{1}{2} \tag{3}$$

$$M_{MO}M_{NC} = \tfrac{1}{2}\sqrt{2} \tag{4}$$

(Bankoff and Garfunkel 1973).

Heptagon Theorem

Let H be a heptagon with seven vertices given in cyclic order inscribed in a CONIC. Then the PASCAL LINES of the seven HEXAGONS obtained by omitting each vertex of H in turn and keeping the remaining vertices in the same cyclic order are the sides of a HEPTAGON I which circumscribes a CONIC.
Moreover, the BRIANCHON POINTS of the seven HEXAGONS obtained by omitting the sides of I one at a time and keeping the remaining sides in the natural cyclic order are the vertices of the original HEPTAGON.

Evelyn, C. J. A.; Money-Coutts, G. B.; and Tyrrell, J. A. "The Heptagon Theorem." §2.1 in *The Seven Circles Theorem and Other New Theorems.* London: Stacey International, pp. 8–1, 1974.

Heptagonal Hexagonal Number

A number which is simultaneously a HEPTAGONAL NUMBER Hep_n and HEXAGONAL NUMBER Hex_m. Such numbers exist when

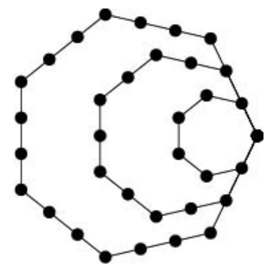
$$\tfrac{1}{2}n(5n-3)=m(2m-1). \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(10n-3)^2-5(4m-1)^2=4. \quad (2)$$

Substituting $x=10n-3$ and $y=4m-1$ gives the Pell-like quadratic Diophantine equation

$$x^2-5y^2=4, \quad (3)$$



which has solutions $(x, y)=(3, 1)$, $(7, 3)$, $(18, 8)$, $(47, 21)$, $(123, 55)$, ... The integer solutions in m and n are then given by $(n, m)=(1, 1)$, $(221, 247)$, $(71065, 79453)$, $(22882613, 25583539)$, ... (Sloane's A048902 and A048901), corresponding to the heptagonal hexagonal numbers 1, 121771, 12625478965, 1309034909945503, ... (Sloane's A048903).

Heptagonal Number

A FIGURATE NUMBER OF THE FORM $n(5n-3)/2$. The first few are 1, 7, 18, 34, 55, 81, 112, ... (Sloane's A000566). The GENERATING FUNCTION for the heptagonal numbers is

$$\frac{x(4x+1)}{(1-x)^3}=x+7x^2+18x^3+34x^4+\ldots.$$

Heptagonal Pentagonal Number

A number which is simultaneously a HEPTAGONAL NUMBER H_n and PENTAGONAL NUMBER P_m. Such numbers exist when

$$\tfrac{1}{2}n(5n-3)=\tfrac{1}{2}m(3m-1). \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$3(10n-3)^2-5(6m-1)^2=22. \quad (2)$$

Substituting $x=10n-3$ and $y=6m-1$ gives the Pell-like quadratic Diophantine equation

$$3x^2-5y^2=22, \quad (3)$$

which has solutions $(x, y)=(3, 1)$, $(7, 5)$, $(17, 13)$, $(53, 41)$, $(133, 103)$, ... The integer solutions in m and n are then given by $(n, m)=(1, 1)$, $(42, 54)$, $(2585, 3337)$, $(160210, 206830)$, $(9930417, 12820113)$ ...

(Sloane's A046198 and A046199), corresponding to the heptagonal pentagonal numbers 1, 4347, 16701685, 64167869935, 246532939589097, ... (Sloane's A048900).

Heptagonal Pyramidal Number

A PYRAMIDAL NUMBER OF THE FORM $n(n+1)(5n-2)/6$, The first few are 1, 8, 26, 60, 115, ... (Sloane's A002413). The GENERATING FUNCTION for the heptagonal pyramidal numbers is

$$\frac{x(4x+1)}{(x-1)^4} = x + 8x^2 + 26x^3 + 60x^4 + \ldots$$

Sloane, N. J. A. Sequences A002413/M4498 in "An On-Line Version of the Encyclopedia of Integer Sequences." http://www.research.att.com/~njas/sequences/eisonline.html.

Heptagonal Square Number

A number which is simultaneously a HEPTAGONAL NUMBER H_n and SQUARE NUMBER S_m. Such numbers exist when

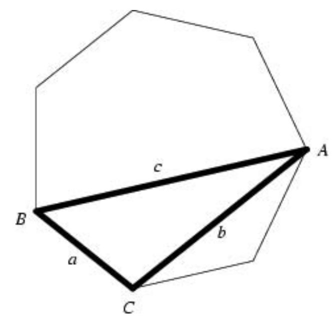
$$\tfrac{1}{2} n(5n-3) = m^2. \tag{1}$$

COMPLETING THE SQUARE and rearranging gives

$$(10n-3)^2 - 40m^2 = 9. \tag{2}$$

Substituting $x = 10n-3$ and $y = 2m$ gives the Pell-like quadratic Diophantine equation

$$x^2 - 10y^2 = 9, \tag{3}$$



which has basic solutions $(x, y) = (7, 2)$, (13, 4), and (57, 18). Additional solutions can be obtained from the unit PELL EQUATION, and correspond to integer solutions when $(n, m) = (1, 1)$, (6, 9), (49, 77), (961, 1519), ... (Sloane's A046195 and A046196), corresponding to the heptagonal square numbers 1, 81, 5929, 2307361, 168662169, 12328771225, ... (Sloane's A036354).

Heptagonal Triangle

The unique (modulo rotations) SCALENE TRIANGLE formed from three vertices of a regular HEPTAGON, having vertex angles $\pi/7$, $2\pi/7$, and $4\pi/7$. There are a number of amazing formulas connecting the sides and angles of the heptagonal triangle (Bankoff and Garfunkel 1973).

The AREA of the TRIANGLE is

$$A = \tfrac{1}{4}\sqrt{7}R^2, \tag{1}$$

where R is the triangle's CIRCUMRADIUS. The sum of squares of sides of the heptagonal triangle is equal to $7R^2$ (Bankoff and Garfunkel 1973). The ratio $x = r/R$ of INRADIUS r to CIRCUMRADIUS R is given by the positive root of

$$8x^3 + 28x^2 + 14x - 7 = 0. \tag{2}$$

Also,

$$\frac{1}{a^2} + \frac{1}{b^2} + \frac{1}{c^2} = \frac{2}{R^2}. \tag{3}$$

The BROCARD ANGLE Ω satisfies

$$\cot\Omega = \sqrt{7}, \tag{4}$$

and the EXRADIUS r_a is equal to the radius of the NINE-POINT CIRCLE of ΔABC.

a is half the HARMONIC MEAN of the other two sides,

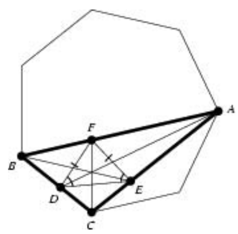
$$a = \frac{bc}{b+c} \tag{5}$$

$$b^2 - a^2 = ac, \tag{6}$$

and so on for all permutations of variables (Bankoff and Garfunkel 1973). Also,

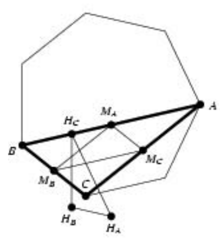
$$\frac{b^2}{a^2} + \frac{c^2}{b^2} + \frac{a^2}{c^2} = 5. \tag{7}$$

If h_a, h_b, and h_c are the altitudes, then

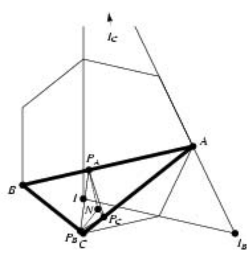


$$h_a = h_b + h_c \tag{8}$$

$$h_a^2 + h_b^2 + h_c^2 = \tfrac{1}{2}(a^2 + b^2 + c^2). \tag{9}$$



If A', B', and C' are the feet of the altitudes, then



$$BA' \cdot A'C = \tfrac{1}{4}ac \qquad (10)$$

and so on (Bankoff and Garfunkel 1973). The internal angle bisectors of C and B are equal to the difference of the adjacent sides and the external angle bisector of A is equal to the sum of adjacent sides.

The triangle ΔDEF joining the feet of the angle bisectors of the heptagonal triangle is an ISOSCELES TRIANGLE with $DF = EF$.

The ORTHIC TRIANGLE $\Delta H_A H_B H_C$ and MEDIAN TRIANGLE $M_A M_B M_C$ are congruent and perspective. In addition both are similar to ΔABC, to the PEDAL TRIANGLE $\Delta P_A P_B P_C$ of ΔABC with respect to the NINE-POINT CENTER N, and to the triangle $\Delta I I_B I_C$ formed by the INCENTER I and the exterior angle bisectors I_B and I_C (Bankoff and Garfunkel 1973).

There are also a slew of curious trigonometric identities involving the angles of the heptagonal triangle:

$$\sin A \sin B \sin C = \tfrac{1}{8}\sqrt{7} \qquad (11)$$

$$\sin^2 A + \sin^2 B + \sin^2 C = \tfrac{7}{4} \qquad (12)$$

$$\sin(2A) + \sin(2B) + \sin(2C) = \tfrac{1}{2}\sqrt{7} \qquad (13)$$

$$\sin^2 A \sin^2 B \sin^2 C = \tfrac{7}{64} \qquad (14)$$

$$\sin^2 A \sin^2 B + \sin^2 A \sin^2 C + \sin^2 B \sin^2 C = \tfrac{7}{8} \qquad (15)$$

$$\cos A \cos B \cos C = -\tfrac{1}{8} \qquad (16)$$

$$\cos^2 A + \cos^2 B + \cos^2 C = \tfrac{5}{4} \qquad (17)$$

$$\cos^2 A \cos^2 B + \cos^2 A \cos^2 C + \cos^2 B \cos^2 C = \tfrac{3}{8} \qquad (18)$$

$$\cos(2A) + \cos(2B) + \cos(2C) = -\tfrac{1}{2} \qquad (19)$$

$$\sin A + \sin B + \sin C = \tfrac{1}{2}\sqrt{14} \qquad (20)$$

$$\tan A \tan B \tan C = -\sqrt{7} \qquad (21)$$

$$\cot A + \cot B + \cot C = \sqrt{7} \qquad (22)$$

$$\csc^2 A + \csc^2 B + \csc^2 C = 8 \qquad (23)$$

$$\sec^2 A + \sec^2 B + \sec^2 C = 24 \qquad (24)$$

$$\cot^2 A + \cot^2 B + \cot^2 C = 5 \qquad (25)$$

$$\tan^2 A + \tan^2 B + \tan^2 C = 21 \qquad (26)$$

$$\sec^4 A + \sec^4 B + \sec^4 C = 416 \qquad (27)$$

$$\cos^4 A + \cos^4 B + \cos^4 C = \tfrac{13}{16} \qquad (28)$$

$$\sin^4 A + \sin^4 B + \sin^4 C = \tfrac{21}{16} \qquad (29)$$

$$\csc^4 A + \csc^4 B + \csc^4 C = 32 \qquad (30)$$

$$\sec(2A) + \sec(2B) + \sec(2C) = -4 \qquad (31)$$

(Bankoff and Garfunkel 1973).

Finally, the heptagonal triangle satisfies the miscellaneous properties:

1. The first BROCARD POINT corresponds to the NINE-POINT CENTER and the second BROCARD POINT lies on the NINE-POINT CIRCLE.
2. $OH = R\sqrt{2}$, where O is the CIRCUMCENTER, H is the ORTHOCENTER, and R is the CIRCUMRADIUS.
3. $IH = (R^2 + 4r^2)/2$, where I is the INCENTER and r is the INRADIUS.
4. The two tangents from the ORTHOCENTER H to the CIRCUMCIRCLE of the heptagonal triangle are mutually perpendicular.
5. The center of the CIRCUMCIRCLE of the TANGENTIAL TRIANGLE corresponds with the symmetric point of O with respect to H.
6. The ALTITUDE from B is half the length of the internal bisector of the angle A.

Heptagonal Triangular Number

A number which is simultaneously a HEPTAGONAL NUMBER H_n and TRIANGULAR NUMBER T_m. Such numbers exist when

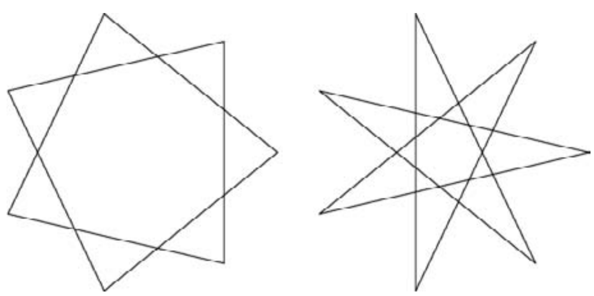
$$\tfrac{1}{2}n(5n-3) = \tfrac{1}{2}m(m+1). \qquad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(10n-3)^2 - 5(2m+1)^2 = 4. \qquad (2)$$

Substituting $x = 10n - 3$ and $y = 2m + 1$ gives the Pell-like quadratic Diophantine equation

$$x^2 - 5y^2 = 4, \qquad (3)$$



which has basic solutions $(x, y) = (3, 1)$, $(7, 3)$, and $(18, 8)$. Additional solutions can be obtained from the unit PELL EQUATION, and correspond to integer solutions when $(n, m) = (1, 1)$, $(5, 10)$, $(221, 493)$, $(1513, 3382)$, ... (Sloane's A046193 and A039835), corresponding to the heptagonal triangular numbers 1, 55, 121771, 5720653, 12625478965, ... (Sloane's A046194).

Heptahedron

A heptahedron is a POLYHEDRON with seven faces. There are 34 topologically distinct convex heptahedra, corresponding to the HEPTAHEDRAL GRAPHS.

The "regular" heptahedron is a one-sided surface made from four TRIANGLES and three QUADRILATERALS. It is topologically equivalent to the ROMAN SURFACE (Wells 1991). While all of the faces are regular and vertices equivalent, the heptahedron is self-intersecting and is therefore not considered an ARCHIMEDEAN SOLID.

There are three semiregular heptahedra: the PENTAGONAL PRISM and PENTAGRAMMIC PRISM (illustrated above), and a FACETED version of the OCTAHEDRON (Holden 1991).

Hermit Point

ISOLATED POINT

Hermite Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

The Hermite constant is defined for DIMENSION n as the value

$$\gamma_n = \frac{\sup_f \min_{x_i} f(x_1, x_2, \ldots, x_n)}{[\text{discriminant}(f)]^{1/n}}$$

(Le Lionnais 1983). In other words, they are given by

$$\gamma_n = 4\left(\frac{\delta_n}{V_n}\right)^{2/n},$$

where δ_n is the maximum *lattice* PACKING DENSITY for HYPERSPHERE PACKING and V_n is the CONTENT of the n-HYPERSPHERE. The first few values of $(\gamma_n)^n$ are 1, 4/3, 2, 4, 8, 64/3, 64, 256, ... (Sloane's A007361 and A007362). Values for larger n are not known.

For sufficiently large n,

$$\frac{1}{2\pi e} \le \frac{\gamma_n}{n} \le \frac{1.744\ldots}{2\pi e}.$$

Hermite Differential Equation

The second-order ordinary linear differential equation

$$\frac{d^2y}{dx^2} - 2x\frac{dy}{dx} + \lambda y = 0. \qquad (1)$$

This differential equation has an irregular singular-

ity at ∞. It can be solved using the series method

$$\sum_{n=0}^{\infty}(n+2)(n+1)a_{n+2}x^n - \sum_{n=1}^{\infty} 2na_nx^n + \sum_{n=0}^{\infty} \lambda a_nx^n = 0 \quad (2)$$

$$(2a_2+\lambda a_0)+\sum_{n=1}^{\infty}[(n+2)(n+1)]a_{n+2}-2na_n+\lambda a_n]x^n = 0. \quad (3)$$

Therefore,

$$a_2 = -\frac{\lambda a_0}{2} \quad (4)$$

and

$$a_{n+2} = \frac{2n-\lambda}{(n+2)(n+1)}a_n \quad (5)$$

for $n = 1, 2, \ldots$. Since (4) is just a special case of (5),

$$a_{n+2} = \frac{2n-\lambda}{(n+2)(n+1)}a_n \quad (6)$$

for $n = 0, 1, \ldots$.

The linearly independent solutions are then

$$y_1 = a_0\left[1-\frac{\lambda}{2!}x^2-\frac{(4-\lambda)\lambda}{4!}x^4-\frac{(8-\lambda)(4-\lambda)\lambda}{6!}x^6-\ldots\right] \quad (7)$$

$$y_2 = a_1\left[x+\frac{(2-\lambda)}{3!}x^3+\frac{(6-\lambda)(2-\lambda)}{5!}x^5+\ldots\right]. \quad (8)$$

These can be done in closed form as

$$y = a_0\,{}_1F_1(-\tfrac{1}{4}\lambda;\ \tfrac{1}{2};\ x^2)+a_1x\,{}_1F_1(-\tfrac{1}{4}(\lambda-2);\ \tfrac{3}{2};\ x^2) \quad (9)$$

$$= a_0\,{}_1F_1(-\tfrac{1}{4}\lambda;\ \tfrac{1}{2};\ x^2)+a_2H_{\lambda/2}(x), \quad (10)$$

where ${}_1F_1(a;\ b;\ x)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND and $H_n(x)$ is a HERMITE POLYNOMIAL. In particular, for $\lambda = 0, 2, 4, \ldots$, the solutions can be written

$$y_{\lambda=0} = a_0+\tfrac{1}{2}\sqrt{\pi}a_1\ \mathrm{erfi}(x) \quad (11)$$

$$y_{\lambda=2} = a_0\left[e^{x^2}-\sqrt{\pi}\,x\ \mathrm{erfi}(x)\right]+xa_1 \quad (12)$$

$$y_{\lambda=4} = \tfrac{1}{4}\{2e^{x^2}xa_1-(2x^2-1)[4a_0+\sqrt{\pi}\,a_1\ \mathrm{erfi}(x)]\}, \quad (13)$$

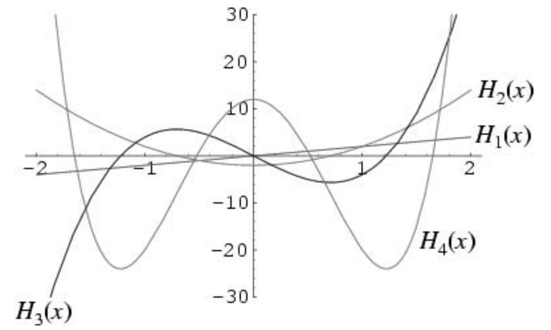
where $\mathrm{erfi}(x)$ is the ERFI function.

If $\lambda = 0$, then Hermite's differential equation becomes

$$y''-2xy' = 0, \quad (14)$$

which is OF THE FORM $P_2(x)y''+P_1(x)y' = 0$ and so has solution

$$y = c_1\int\frac{dx}{\exp\left(\int\frac{P_1}{P_2}dx\right)}+c_2$$



$$= c_1\int\frac{dx}{\exp\int(-2x)\,dx}+c_2$$

$$= c_1\int\frac{dx}{e^{-x^2}}+c_2 = c_1\ \mathrm{erfi}(x)+c_2. \quad (15)$$

Hermite Interpolation

HERMITE'S INTERPOLATING POLYNOMIAL

Hermite Polynomial

A set of ORTHOGONAL POLYNOMIALS $H_n(x)$, illustrated above for $x \in [0, 1]$ and $n = 1, 2, \ldots, 5$. Roman (1984, pp. 87–3) defines a generalized Hermite polynomial $H_n^{(\nu)}(x)$ of variance ν.

The Hermite polynomials are a SHEFFER SEQUENCE with

$$g(t) = e^{t^2/4} \quad (1)$$

$$f(t) = \tfrac{1}{2}t \quad (2)$$

(Roman 1984, p. 30), giving the GENERATING FUNCTION

$$\exp(2xt-t^2) \equiv \sum_{n=0}^{\infty}\frac{H_n(x)t^n}{n!}. \quad (3)$$

Using a TAYLOR SERIES shows that

$$H_n(x) = \left[\left(\frac{\partial}{\partial t}\right)^n \exp(2xt-t^2)\right]_{t=0}$$

$$= \left[e^{x^2}\left(\frac{\partial}{\partial t}\right)^n e^{-(x-t)^2}\right]_{t=0}. \quad (4)$$

Since $\partial f(x-t)/\partial t = -\partial f(x-t)/\partial x$,

$$H_n(x) = (-1)^n e^{x^2}\left[\left(\frac{\partial}{\partial x}\right)^n e^{-(x-t)^2}\right]_{t=0}$$

$$= (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}. \quad (5)$$

Now define operators

$$\tilde{O}_1 \equiv -e^{x^2} \frac{d}{dx} e^{-x^2} \quad (6)$$

$$\tilde{O}_2 \equiv e^{x^2/2}\left(x - \frac{d}{dx}\right)e^{-x^2/2}. \quad (7)$$

It follows that

$$\tilde{O}_1 f = -e^{x^2} \frac{d}{dx}[fe^{-x^2}] = 2xf - \frac{df}{dx} \quad (8)$$

$$\tilde{O}_2 f = e^{x^2/2}\left(x - \frac{d}{dx}\right)[fe^{-x^2/2}]$$

$$= xf + xf - \frac{df}{dx} = 2xf - \frac{df}{dx}, \quad (9)$$

so

$$\tilde{O}_1 = \tilde{O}_2, \quad (10)$$

and

$$-e^{x^2} \frac{d}{dx} e^{-x^2} = e^{x^2/2}\left(x - \frac{d}{dx}\right)e^{-x^2/2} \quad (11)$$

(Arfken 1985, p. 720), which means the following definitions are equivalent:

$$\exp(2xt - t^2) \equiv \sum_{n=0}^{\infty} \frac{H_n(x)t^n}{n!} \quad (12)$$

$$H_n(x) \equiv (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2} \quad (13)$$

$$H_n(x) \equiv e^{x^2/2}\left(x - \frac{d}{dx}\right)^n e^{-x^2/2} \quad (14)$$

(Arfken 1985, pp. 712–13 and 720).

The Hermite polynomials may be written as

$$H_n(x) = (2x)^n \, {}_2F_0(-n/2, \; -(n-1)/2;\,; \; -1/x^2) \quad (15)$$

(Koekoek and Swarttouw 1998), or

$$H_n(x) = 2^n U(-\tfrac{1}{2}n, \; \tfrac{1}{2}, \; x^2), \quad (16)$$

where $U(a, b, x)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND. The Hermite polynomials are related to the derivative of the ERROR FUNCTION by

$$H_n(z) = (-1)^2 \frac{\sqrt{\pi}}{2} e^{z^2} \frac{d^{n+1}}{dz^{n+1}} \operatorname{erf}(z). \quad (17)$$

They have a CONTOUR INTEGRAL representation

$$H_n(x) = \frac{n!}{2\pi i} \int e^{-t^2+2tx} t^{-n-1} \, dt. \quad (18)$$

They are orthogonal in the range $(-\infty, \infty)$ with respect to the WEIGHTING FUNCTION e^{-x^2}

$$\int_{-\infty}^{\infty} H_m(x) H_n(x) e^{-x^2} \, dx = \delta_{mn} 2^n n! \sqrt{\pi}. \quad (19)$$

The first few POLYNOMIALS are

$H_0(x) = 1$

$H_1(x) = 2x$

$H_2(x) = 4x^2 - 2$

$H_3(x) = 8x^3 - 12x$

$H_4(x) = 16x^4 - 48x^2 + 12$

$H_5(x) = 32x^5 - 160x^3 + 120x$

$H_6(x) = 64x^6 - 480x^4 + 720x^2 - 120$

$H_7(x) = 128x^7 - 1344x^5 + 3360x^3 - 1680x$

$H_8(x) = 256x^8 - 3584x^6 + 13440x^4 - 13440x^2 + 1680$

$H_9(x) = 512x^9 - 9216x^7 + 48348x^5 - 80640x^3 + 30240x$

$$H_{10}(x) = 1024x^{10} - 23040x^8 + 161280x^6 - 403200x^4 + 302400x^2 - 30240.$$

The Hermite polynomials obey the orthogonality conditions

$$\int_{-\infty}^{\infty} u_n(x) \frac{du_m}{dx} \, dx = \begin{cases} a\sqrt{\frac{n+1}{2}} & m = n+1 \\ -a\sqrt{\frac{n}{2}} & m = n-1 \\ 0 & \text{otherwise} \end{cases} \quad (20)$$

$$\int_{-\infty}^{\infty} u_m(x) u_n(x) \, dx = \delta_{mn} \quad (21)$$

$$\int_{-\infty}^{\infty} u_m(x) x u_n(x) \, dx = \begin{cases} \frac{1}{a}\sqrt{\frac{n+1}{2}} & m = n+1 \\ \frac{1}{a}\sqrt{\frac{n}{2}} & m = n-1 \\ 0 & \text{otherwise} \end{cases} \quad (22)$$

$$\int_{-\infty}^{\infty} u_m(x) x^2 u_n(x) \, dx = \begin{cases} \frac{2n+1}{2a^2} & m = n \\ \frac{\sqrt{(n+1)(n+2)}}{2a^2} & m = n+2 \\ 0 & m \neq n \neq n \pm 2 \end{cases} \quad (23)$$

$$\int_{-\infty}^{\infty} e^{-x^2} H_\alpha H_\beta H_\gamma \, dx = \sqrt{\pi} \frac{2^s \alpha! \beta! \gamma!}{(s-\alpha)!(s-\beta)!(s-\gamma)!}, \tag{24}$$

if $\alpha+\beta+\gamma=2s$ is EVEN and $s \geq \alpha$, $s \geq \beta$, and $s \geq \gamma$. Otherwise, the last integral is 0 (Szego 1975, p. 390).

They also satisfy the RECURRENCE RELATIONS

$$H_{n+1}(x) = 2xH_n(x) - 2nH_{n-1}(x) \tag{25}$$

$$H_n'(x) = 2nH_{n-1}(x). \tag{26}$$

By solving the HERMITE DIFFERENTIAL EQUATION, the series

$$H_{2k}(x) = (-1)^k 2^k (2k-1)!! \times \left[1 + \sum_{j=1}^{k} \frac{(-4k)(-4k+4)\cdots(-4k+4j-4)}{(2j)!} x^{2j}\right] \tag{27}$$

$$H_{2k+1}(x) = (-1)^k 2^{k+1} (2k+1)!! \times \left[x + \sum_{j=1}^{k} \frac{(-4k)(-4k+4)\cdots(-4k+4j-4)}{(2j+1)!} x^{2j+1}\right] \tag{28}$$

are obtained, where the products in the numerators are equal to

$$(-4k)(-4k+4)\cdots(-4k+4j-4) = 4^j(-k)_j, \tag{29}$$

with $(x)_n$ the POCHHAMMER SYMBOL.

The DISCRIMINANT is

$$D_n = 2^{3n(n-1)/2} \prod_{k=1}^{n} k^k \tag{30}$$

(Szego 1975, p. 143), a normalized form of the HYPERFACTORIAL, the first few values of which are 1, 32, 55296, 7247757312, 92771293593600000, ... (Sloane's A054374). The table of RESULTANTS is given by {0}, {−8, 0}, {0, −2048, 0}, {192, 16384, 28311552, 0}, ... (Sloane's A054373).

Two interesting identities involving $H_n(x+y)$ are given by

$$\sum_{k=0}^{n} \binom{n}{k} H_k(x) H_{n-k}(y) = 2^{n/2} H_n(2^{-1/2}(x+y)) \tag{31}$$

and

$$\sum_{k=0}^{n} \binom{n}{k} H_k(x)(2y)^{n-k} = H_n(x+y) \tag{32}$$

(G. Colomer).

A set of associated functions is defined by

$$u_n(x) \equiv \sqrt{\frac{a}{\pi^{1/2} n! 2^n}} H_n(ax) e^{-a^2x^2/2}. \tag{33}$$

A class of generalized Hermite POLYNOMIALS $\gamma_n^m(x)$ satisfying

$$e^{mxt-t^m} = \sum_{n=0}^{\infty} \gamma_n^m(x) t^n \tag{34}$$

was studied by Subramanyan (1990). A class of related POLYNOMIALS defined by

$$h_{n,m} = \gamma_n^m \left(\frac{2x}{m}\right) \tag{35}$$

and with GENERATING FUNCTION

$$e^{2xt-t^m} = \sum_{n=0}^{\infty} h_{n,m}(x) t^n \tag{36}$$

was studied by Djordjevic (1996). They satisfy

$$H_n(x) = n! h_{n,\,2}(x). \tag{37}$$

A modified version of the HERMITE POLYNOMIAL is sometimes defined by

$$He_n(x) \equiv H_n\left(\frac{x}{\sqrt{2}}\right). \tag{38}$$

Hermite Quadrature

HERMITE-GAUSS QUADRATURE

Hermite's Interpolating Polynomial

Let $l(x)$ be an nth degree POLYNOMIAL with zeros at $x_1, ..., x_n$. Then the fundamental Hermite interpolating polynomials of the first and second kinds are defined by

$$h_\nu^{(1)}(x) = \left[1 - \frac{l''(x_\nu)}{l'(x_\nu)}\right][l_\nu(x)]^2 \tag{1}$$

and

$$h_\nu^{(2)}(x) = (x - x_\nu)[l_\nu(x)]^2 \tag{2}$$

for $\nu = 1, 2, .., .n$. These polynomials have the properties

$$h_\nu^{(1)}(x_\mu) = \delta_{\nu\mu} \tag{3}$$

$$h_\nu^{(1)'}(x_\mu) = 0 \tag{4}$$

$$h_\nu^{(2)}(x_\mu) = 0 \tag{5}$$

$$h_\nu^{(2)'}(x_\mu) = \delta_{\nu\mu}. \tag{6}$$

for $\mu,\ \nu = 1, 2, ..., n$. Now let $f_1, ..., f_n$ and $f_1', ..., f_n'$ be values. Then the expansion

$$W_n(x) = \sum_{\nu=1}^{n} f_\nu h_\nu^{(1)}(x) + \sum_{\nu=1}^{n} f_\nu' h_\nu^{(2)}(x) \tag{7}$$

gives the unique Hermite interpolating fundamental polynomial for which

$$W_n(x_\nu) = f_\nu \tag{8}$$

$$W_n'(x_\nu) = f_\nu'. \tag{9}$$

If $f_\nu' = 0$, these are called STEP POLYNOMIALS.

The fundamental polynomials satisfy

$$h_1(x) + \ldots + h_n(x) = 1 \tag{10}$$

and

$$\sum_{\nu=1}^{n} x_\nu h_\nu^{(1)}(x) + \sum_{\nu=1}^{n} h_\nu^{(2)}(x) = x. \tag{11}$$

Also, if $d\alpha(x)$ is an arbitrary distribution on the interval $[a, b]$, then

$$\int_a^b h_\nu^{(1)}(x)\, d\alpha(x) = \lambda_\nu \tag{12}$$

$$\int_a^b h_\nu^{(1)'}(x)\, d\alpha(x) = 0 \tag{13}$$

$$\int_a^b x h_\nu^{(1)'}(x)\, d\alpha(x) = 0 \tag{14}$$

$$\int_a^b h_\nu^{(2)}(x)\, d\alpha(x) = 0 \tag{15}$$

$$\int_a^b h_\nu^{(2)'}(x)\, d\alpha(x) = \lambda_\nu \tag{16}$$

$$\int_a^b x h_\nu^{(2)'}(x)\, d\alpha(x) = \lambda_\nu x_\nu, \tag{17}$$

where λ_ν are CHRISTOFFEL NUMBERS.

See also CHRISTOFFEL NUMBER, LAGRANGE INTERPOLATING POLYNOMIAL

Hermite's Theorem

E is TRANSCENDENTAL.

See also E, TRANSCENDENTAL NUMBER.

Hermite-Gauss Quadrature

Also called HERMITE QUADRATURE. A GAUSSIAN QUADRATURE over the interval $(-\infty,\ \infty)$ with WEIGHTING FUNCTION $W(x) = e^{-x^2}$ (Abramowitz and Stegun 1972, p. 890). The ABSCISSAS for quadrature order n are given by the roots of the HERMITE POLYNOMIALS $H_n(x)$, which occur symmetrically about 0. The WEIGHTS are

$$w_i = -\frac{A_{n+1}\gamma_n}{A_n H_n'(x_i) H_{n+1}(x_i)} = \frac{A_n}{A_{n-1}} \frac{\gamma_{n-1}}{H_{n-1}(x_1) H_n'(x_i)}, \tag{1}$$

where A_n is the COEFFICIENT of x^n in $H_n(x)$. For HERMITE POLYNOMIALS,

$$A_n = 2^n, \tag{2}$$

so

$$\frac{A_{n+1}}{A_n} = 2. \tag{3}$$

Additionally,

$$\gamma_n = \sqrt{\pi}\, 2^n n!, \tag{4}$$

so

$$w_i = -\frac{2^{n+1} n!\, \sqrt{\pi}}{H_{n+1}(x_i) H_n'(x_i)} = \frac{2^n (n-1)!\, \sqrt{\pi}}{H_{n-1}(x_i) H_n'(x_i)}. \tag{5}$$

Using the RECURRENCE RELATION

$$H_n'(x) = 2nH_{n-1}(x) = 2xH_n(x) - H_{n+1}(x) \tag{6}$$

yields

$$H_n'(x_i) = 2nH_{n-1}(x_i) = -H_{n+1}(x_i) \tag{7}$$

and gives

$$w_i = \frac{2^{n+1} n!\, \sqrt{\pi}}{[H_n'(x_i)]^2} = \frac{2^{n+1} n!\, \sqrt{\pi}}{[H_{n+1}(x_i)]^2}. \tag{8}$$

The error term is

$$E = \frac{n!\, \sqrt{\pi}}{2^n (2n)!} f^{(2n)}(\xi). \tag{9}$$

Beyer (1987) gives a table of ABSCISSAS and weights up to $n = 12$.

n	x_i	w_i
2	$\pm$ 0.707107	0.886227
3	0	1.18164
	$\pm$ 1.22474	0.295409
4	$\pm$ 0.524648	0.804914
	$\pm$ 1.65068	0.0813128
5	0	0.945309
	$\pm$ 0.958572	0.393619
	$\pm$ 2.02018	0.0199532

The ABSCISSAS and weights can be computed analytically for small n.

n	x_i	w_i
2	$\pm\frac{1}{2}\sqrt{2}$	$\frac{1}{2}\sqrt{\pi}$
3	0	$\frac{2}{3}\sqrt{\pi}$
	$\pm\frac{1}{2}\sqrt{6}$	$\frac{1}{6}\sqrt{\pi}$
4	$\pm\sqrt{\frac{3-\sqrt{6}}{2}}$	$\frac{\sqrt{\pi}}{4(3-\sqrt{6})}$
	$\pm\sqrt{\frac{3+\sqrt{6}}{2}}$	$\frac{\sqrt{\pi}}{4(3+\sqrt{6})}$

HermiteH

HERMITE POLYNOMIAL

Hermite-Lindemann Theorem

Let α_i and A_1 be ALGEBRAIC NUMBERS such that the A_i s differ from zero and the α_is differ from each other. Then the expression

$$A_1 e^{\alpha_1} + A_2 e^{\alpha_2} + A_3 e^{\alpha_3} + \ldots$$

cannot equal zero. The theorem was proved by Hermite (1873) in the special case of the A_is and α_is RATIONAL INTEGERS, and subsequently proved for algebraic numbers by Lindemann (1882). The proof was subsequently simplified by Weierstrass (1885) and Gordan (1893).

See also ALGEBRAIC NUMBER, CONSTANT PROBLEM, FOUR EXPONENTIALS CONJECTURE, INTEGER RELATION, LINDEMANN-WEIERSTRASS THEOREM, SIX EXPONENTIALS THEOREM

Hermitian Conjugate

ADJOINT

Hermitian Form

A combination of variables x and y given by

$$ax\bar{x} + bx\bar{y} + \bar{b}\bar{x}y + cy\bar{y},$$

where $\bar{b}$, $\bar{x}$ and $\bar{y}$ are COMPLEX CONJUGATES.

Hermitian Inner Product

A Hermitian inner product on a COMPLEX VECTOR SPACE V is a complex-valued BILINEAR FORM on V which is ANTILINEAR in the second slot, and is positive definite. That is, it satisfies the following properties, where $\bar{z}$ denotes the COMPLEX CONJUGATE of z.

1. $\langle u+v,\ w\rangle = \langle u,\ w\rangle + \langle v,\ w\rangle$
2. $\langle u,\ v+w\rangle = \langle u,\ v\rangle + \langle u,\ w\rangle$
3. $\langle \alpha u,\ v\rangle = \alpha\langle u,\ v\rangle$
4. $\langle u,\ \alpha v\rangle = \bar{\alpha}\langle u,\ v\rangle$
5. $\langle u,\ v\rangle = \overline{\langle v,\ u\rangle}$
6. $\langle u,\ u\rangle \geq 0$, with equality only if $u = 0$

The basic example is the form

$$h(z,\ w) = \sum z_i \bar{w}_i \tag{1}$$

on $\mathbb{C}^n$, where $z = (z_1,\ \ldots,\ z_n)$ and $w = (w_1,\ \ldots,\ w_n)$. Note that by writing $z_k = x_k + iy_k$, it is possible to consider $\mathbb{C}^n \sim \mathbb{R}^{2n}$, in which case $\Re[h]$ is the Euclidean INNER PRODUCT and $\Im[h]$ is a nondegenerate alternating BILINEAR FORM, i.e., a SYMPLECTIC FORM. Explicitly, in $\mathbb{C}^2$, the standard Hermitian form is expressed below.

$$h((z_{11},\ z_{12}),\ (z_{21},\ z_{22})) = x_{11}, x_{21} + x_{12}x_{22} + y_{11}y_{21}$$
$$+ y_{12}y_{22} + i(x_{21}y_{11} - x_{11}y_{21} + x_{22}y_{12} - x_{12}y_{22}). \tag{2}$$

A generic Hermitian inner product has its REAL PART symmetric positive definite, and its IMAGINARY PART symplectic by properties 5 and 6. A matrix $\mathsf{H} = (h_{ij})$ defines an antilinear form, satisfying 1–, by $\langle e_i,\ e_j\rangle = h_{ij}$ IFF H is a HERMITIAN MATRIX. It is positive definite (satisfying 6) when $\Re[\mathsf{H}]$ is a POSITIVE DEFINITE MATRIX. In matrix form,

$$\langle v,\ w\rangle = v^{\mathrm{T}}\mathsf{H}\bar{w} \tag{3}$$

and the canonical Hermitian inner product is when H is the IDENTITY MATRIX.

See also COMPLEX NUMBER, HERMITIAN METRIC, INNER PRODUCT, POSITIVE DEFINITE QUADRATIC FORM, SYMPLECTIC FORM, UNITARY BASIS, UNITARY GROUP, UNITARY MATRIX, VECTOR SPACE

Hermitian Matrix

A SQUARE MATRIX is called Hermitian if it is SELF-ADJOINT. Therefore, a Hermitian matrix is defined as one for which

$$\mathsf{A} = \mathsf{A}^* \tag{1}$$

where A^* denotes the ADJOINT MATRIX. For example,

$$\mathsf{A} = \begin{bmatrix} 1 & 1+i & 2i \\ 1-i & 5 & -3 \\ -2i & -3 & 0 \end{bmatrix} \tag{2}$$

is a Hermitian matrix.

An INTEGER or REAL MATRIX is Hermitian iff it is SYMMETRIC. A matrix m can be tested to see if it is Hermitian using the *Mathematica* function

```
HermitianQ[m_List?MatrixQ] := (m ===
Conjugate@Transpose@m)
```

Hermitian matrices have REAL EIGENVALUES whose EIGENVECTORS form a UNITARY BASIS. For REAL MATRICES, Hermitian is the same as SYMMETRIC.

Any MATRIX C which is not Hermitian can be expressed as the sum a Hermitian matrix and a SKEW HERMITIAN MATRIX using

$$\mathsf{C} = \tfrac{1}{2}(\mathsf{C} + \mathsf{C}^*) + \tfrac{1}{2}(\mathsf{C} - \mathsf{C}^*). \tag{3}$$

Let U be a UNITARY MATRIX and A be a Hermitian matrix. Then the ADJOINT MATRIX of a SIMILARITY TRANSFORMATION is

$$(\mathsf{UAU}^{-1}) = [(\mathsf{UA})(\mathsf{U}^{-1})]^* = (\mathsf{U}^{-1})^*(\mathsf{UA})^*$$
$$= (\mathsf{U}^*)^*(\mathsf{A}^*\mathsf{U}^*) = \mathsf{UAU}^* = \mathsf{UAU}^{-1}. \tag{4}$$

The specific matrix

$$\mathsf{H}(x,\ y,\ z) = \begin{bmatrix} z & x+iy \\ x-iy & -z \end{bmatrix} = x\mathsf{P}_1 + y\mathsf{P}_2 + z\mathsf{P}_3, \tag{5}$$

where P_i are PAULI SPIN MATRICES, is sometimes called "the" Hermitian matrix.

See also ADJOINT MATRIX, HERMITIAN OPERATOR, NORMAL MATRIX, PAULI SPIN MATRICES, SKEW HERMITIAN MATRIX, SYMMETRIC MATRIX

Hermitian Metric

A Hermitian metric on a COMPLEX VECTOR BUNDLE assigns a HERMITIAN INNER PRODUCT to every FIBER. The basic example is the TRIVIAL BUNDLE $\pi : U \times \mathbb{C}^k \to U$, where U is an OPEN SET in $\mathbb{R}^n$. Then a positive definite HERMITIAN MATRIX H defines a

Hermitian metric by

$$\langle v,\ w\rangle = v^{\mathrm{T}}\mathsf{H}\bar{w},$$

where $\bar{w}$ is the COMPLEX CONJUGATE of w. By a PARTITION OF UNITY, any COMPLEX VECTOR BUNDLE has a Hermitian metric.

In the special case of a COMPLEX MANIFOLD, the complexified TANGENT BUNDLE $TM \otimes \mathbb{C}$ may have a Hermitian metric, in which case its REAL PART is a RIEMANNIAN METRIC and its IMAGINARY PART is a nondegenerate ALTERNATING MULTILINEAR FORM ω. When ω is CLOSED, i.e., in this case a SYMPLECTIC FORM, then ω is a KÄHLER FORM.

On a HOLOMORPHIC VECTOR BUNDLE with a Hermitian metric h, there is a unique connection compatible with h and the complex structure. Namely, it must be $\nabla = \partial + \bar{\partial}$, where $\partial s = h^{-1}\partial hs$ in a TRIVIALIZATION.

See also COMPLEX GEOMETRY, COMPLEX MANIFOLD, COMPLEX VECTOR BUNDLE, HOLOMORPHIC VECTOR BUNDLE, KÄHLER FORM, KÄHLER MANIFOLD, RIEMANNIAN METRIC, SYMPLECTIC FORM, UNITARY GROUP

Hermitian Operator

A Hermitian OPERATOR $\tilde{L}$ is one which satisfies

$$\int_a^b \bar{v}\tilde{L}u\ dx = \int_a^b u\tilde{L}\bar{v}\ dx. \tag{1}$$

where $\bar{z}$ denotes a COMPLEX CONJUGATE. As shown in STURM-LIOUVILLE THEORY, if $\tilde{L}$ is SELF-ADJOINT and satisfies the boundary conditions

$$\bar{v}pu'|_{x=a} = \bar{v}pu'|_{x=b}, \tag{2}$$

then it is automatically Hermitian. Hermitian operators have REAL EIGENVALUES, ORTHOGONAL EIGENFUNCTIONS, and the corresponding EIGENFUNCTIONS form a COMPLETE set when $\tilde{L}$ is second-order and linear.

In order to prove that EIGENVALUES must be REAL and EIGENFUNCTIONS ORTHOGONAL, consider

$$\tilde{L}u_i + \lambda_i w u_i = 0. \tag{3}$$

Assume there is a second EIGENVALUE λ_j such that

$$\tilde{L}u_j + \lambda_j w u_j = 0 \tag{4}$$

$$\tilde{L}\bar{u}_j + \bar{\lambda}_j w \bar{u}_j = 0. \tag{5}$$

Now multiply (3) by $\bar{u}_j$ and (5) by u_i

$$\bar{u}_j\tilde{L}u_i + \bar{u}_j\lambda w u_i = 0 \tag{6}$$

$$u_i\tilde{L}\bar{u}_j + u_i\bar{\lambda}_j w\bar{u}_j = 0 \tag{7}$$

$$\bar{u}_i\tilde{L}u_i - u_i\tilde{L}\bar{u}_j = (\bar{\lambda}_j - \lambda_i)wu_i\bar{u}_j. \tag{8}$$

Now integrate

$$\int_a^b \bar{u}_j\tilde{L}u_i - \int_a^b u_i\tilde{L}\bar{u}_j = (\bar{\lambda}_j - \lambda_i)\int_a^b wu_i\bar{u}_j. \tag{9}$$

But because $\tilde{L}$ is Hermitian, the left side vanishes.

$$(\bar{\lambda}_j - \lambda_i)\int_a^b wu_i\bar{u}_j = 0. \tag{10}$$

If EIGENVALUES λ_i and λ_j are not degenerate, then $\int_a^b wu_i\bar{u}_j = 0$, so the EIGENFUNCTIONS are ORTHOGONAL. If the EIGENVALUES are degenerate, the EIGENFUNCTIONS are not necessarily orthogonal. Now take $i = j$.

$$(\bar{\lambda}_i - \lambda_i)\int_a^b wu_i\bar{u}_i = 0. \tag{11}$$

The integral cannot vanish unless $u_i = 0$, so we have $\bar{\lambda}_i = \lambda_i$ and the EIGENVALUES are real.

For a Hermitian operator $\tilde{O}$,

$$\langle\phi|\tilde{O}\psi\rangle = \overline{\langle\phi|\tilde{O}\psi\rangle} = \langle\tilde{O}\phi|\psi\rangle. \tag{12}$$

In integral notation,

$$\int \overline{\tilde{A}\phi}\psi\ dx = \int \bar{\phi}\tilde{A}\psi\ dx. \tag{13}$$

Given Hermitian operators $\tilde{A}$ and $\tilde{B}$,

$$\langle\phi|\tilde{A}\tilde{B}\psi\rangle = \langle\tilde{A}\phi|\tilde{B}\psi\rangle = \langle\tilde{B}\tilde{A}\phi|\psi\rangle = \overline{\langle\phi|\tilde{B}\tilde{A}\psi\rangle}. \tag{14}$$

Because, for a Hermitian operator $\tilde{A}$ with EIGENVALUE a,

$$\langle\psi|\tilde{A}\psi\rangle = \langle\tilde{A}\psi|\psi\rangle \tag{15}$$

$$a\langle\psi|\psi\rangle = \bar{a}\langle\psi|\psi\rangle. \tag{16}$$

Therefore, either $\langle\psi|\psi\rangle = 0$ or $a = \bar{a}$. But $\langle\psi|\psi\rangle = 0$ IFF $\psi = 0$, so

$$\langle\psi|\psi\rangle \neq 0, \tag{17}$$

for a nontrivial EIGENFUNCTION. This means that $a = a^*$, namely that Hermitian operators produce REAL expectation values. Every observable must therefore have a corresponding Hermitian operator. Furthermore,

$$\langle\psi_n|\tilde{A}\psi_m\rangle = \langle\tilde{A}\psi_n|\psi_m\rangle \tag{18}$$

$$a_m\langle\psi_n|\psi_m\rangle = \bar{a}_n\langle\psi_n|\psi_m\rangle = a_n\langle\psi_n|\psi_m\rangle, \tag{19}$$

since $a_n = \bar{a}_n$. Then

$$(a_m - a_n)\langle\psi_n|\psi_m\rangle = 0 \tag{20}$$

For $a_m \neq a_n$ (i.e., $\psi_n \neq \psi_m$),

$$\langle\psi_n|\psi_m\rangle = 0. \tag{21}$$

For $a_m = a_n$ (i.e., $\psi_n = \psi_m$),

$$\langle\psi_n|\psi_m\rangle = \langle\psi_n|\psi_n\rangle \equiv 1. \tag{22}$$

Therefore,

$$\langle \psi_n | \psi_m \rangle = \delta_{nm}, \tag{23}$$

so the basis of EIGENFUNCTIONS corresponding to a Hermitian operator are ORTHONORMAL.

Define the Hermitian conjugate operator $\tilde{A}^*$ by

$$\langle \tilde{A}\psi | \psi \rangle \equiv \langle \psi | \tilde{A}^* \psi \rangle. \tag{24}$$

For a Hermitian operator, $\tilde{A} = \tilde{A}^*$. Furthermore, given two Hermitian operators $\tilde{A}$ and $\tilde{B}$,

$$\langle \psi_2 | (\tilde{A}\tilde{B})^* \psi_1 \rangle = \langle (\tilde{A}\tilde{B})\psi_2 | \psi_1 \rangle = \langle \tilde{B}\psi_2 | \tilde{A}^* \psi_1 \rangle$$
$$= \langle \psi_2 | \tilde{B}^* \tilde{A}^* \psi_1 \rangle, \tag{25}$$

so

$$(\tilde{A}\tilde{B})^* = \tilde{B}^* \tilde{A}^*. \tag{26}$$

By further iterations, this can be generalized to

$$(\tilde{A}\tilde{B}\cdots\tilde{Z})^* = \tilde{Z}^* \cdots \tilde{B}^* \tilde{A}^*. \tag{27}$$

Given two Hermitian operators $\tilde{A}$ and $\tilde{B}$,

$$(\tilde{A}\tilde{B})^* = \tilde{B}^* \tilde{A}^* = \tilde{B}\tilde{A} = \tilde{A}\tilde{B} + [\tilde{B}, \tilde{A}], \tag{28}$$

the operator $\tilde{A}\tilde{B}$ equals $(\tilde{A}\tilde{B})^*$, and is therefore Hermitian, only if

$$[\tilde{B}, \tilde{A}] = 0. \tag{29}$$

Given an arbitrary operator $\tilde{A}$,

$$\langle \psi_1 | (\tilde{A} + \tilde{A}^*) \psi_2 \rangle = \langle (\tilde{A}^* + \tilde{A}) \psi_1 | \psi_2 \rangle$$
$$= \langle (\tilde{A} + \tilde{A}^*) \psi_1 | \psi_2 \rangle, \tag{30}$$

so $\tilde{A} + \tilde{A}^*$ is Hermitian.

$$\langle \psi_1 | i(\tilde{A} - \tilde{A}^*) \psi_2 \rangle = \langle -i(\tilde{A}^* - \tilde{A}) \psi_1 | \psi_2 \rangle$$
$$= \langle i(\tilde{A} - \tilde{A}^*) \psi_1 | \psi_2 \rangle, \tag{31}$$

so $i(\tilde{A} - \tilde{A}^*)$ is Hermitian. Similarly,

$$\langle \psi_1 | (\tilde{A}\tilde{A}^*) \psi_2 \rangle = \langle \tilde{A}^* \psi_1 | \tilde{A}^* \psi_2 \rangle = \langle (\tilde{A}\tilde{A}^*) \psi_1 | \psi_2 \rangle, \tag{32}$$

so $\tilde{A}\tilde{A}^*$ is Hermitian.

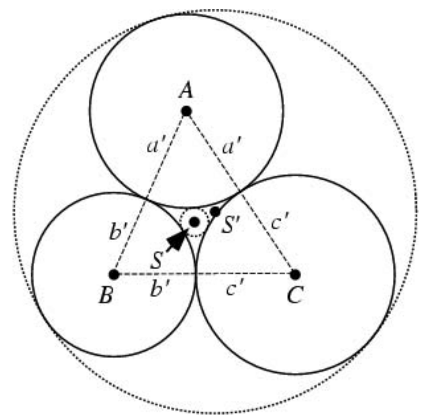
Heron Triangle

HERONIAN TRIANGLE

Heron's Formula

Gives the AREA of a TRIANGLE in terms of the lengths of the sides a, b, and c and the SEMIPERIMETER



$$s = \tfrac{1}{2}(a + b + c). \tag{1}$$

Heron's formula then states

$$\Delta = \sqrt{s(s-a)(s-b)(s-c)}. \tag{2}$$

Heron's formula may be stated beautifully using a CAYLEY-MENGER DETERMINANT as

$$-16\Delta^2 = \begin{vmatrix} 0 & a & b & c \\ a & 0 & c & b \\ b & c & 0 & a \\ c & b & a & 0 \end{vmatrix} = \begin{vmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & c^2 & b^2 \\ 1 & c^2 & 0 & a^2 \\ 1 & b^2 & a^2 & 0 \end{vmatrix}. \tag{3}$$

Expressing the side lengths a, b, and c in terms of the radii a', b', and c' of the mutually tangent circles centered on the TRIANGLE vertices (which define the SODDY CIRCLES),

$$a = b' + c' \tag{4}$$

$$b = a' + c' \tag{5}$$

$$c = a' + b', \tag{6}$$

gives the particularly pretty form

$$\Delta = \sqrt{a'b'c'(a' + b' + c')}. \tag{7}$$

Heron's proof (Dunham 1990) is ingenious but extremely convoluted, bringing together a sequence of apparently unrelated geometric identities and relying on the properties of CYCLIC QUADRILATERALS and RIGHT TRIANGLES. Heron's proof can be found in Proposition 1.8 of his work *Metrica* (ca. 100 BC-100 AD). This manuscript had been lost for centuries until a fragment was discovered in 1894 and a complete copy in 1896 (Dunham 1990, p. 118). More recently, writings of the Arab scholar Abu'l Raihan Muhammed al-Biruni have credited the formula to Heron's predecessor Archimedes prior to 212 BC (van der Waerden 1961, pp. 228 and 277; Coxeter and Greitzer 1967, p. 59; Kline 1972; Bell 1986, p. 58; Dunham 1990, p. 127).

A much more accessible algebraic proof proceeds from the LAW OF COSINES,

$$\cos A = \frac{b^2 + c^2 - a^2}{2bc}. \quad (8)$$

Then

$$\sin A = \frac{\sqrt{-a^4 - b^4 - c^4 + 2b^2c^2 + 2c^2a^2 + 2a^2b^2}}{2bc}, \quad (9)$$

giving

$$\Delta = \sqrt{s(s-a)(s-b)(s-c)} \quad (10)$$

$$= \tfrac{1}{4}\sqrt{(2ab)^2 - (a^2+b^2-c^2)^2} \quad (11)$$

$$= \tfrac{1}{2}\, bc \sin A \quad (12)$$

$$= \tfrac{1}{4}\sqrt{(a+b+c)(-a+b+c)(a-b+c)(a+b-c)}$$

$$= \tfrac{1}{4}\sqrt{2(b^2c^2 + c^2a^2 + a^2b^2) - (a^4 + b^4 + c^4)} \quad (13)$$

(Coxeter 1969). Heron's formula contains the PYTHAGOREAN THEOREM as a degenerate case.

Heronian Triangle

A TRIANGLE with RATIONAL side lengths and RATIONAL AREA. Brahmagupta gave a parametric solution for *integer* Heronian triangles (the three side lengths and area can be multiplied by their LEAST COMMON MULTIPLE to make them all INTEGERS): side lengths $c(a^2+b^2)$, $b(a^2+c^2)$, and $(b+c)(a^2-bc)$, giving SEMIPERIMETER

$$s = a^2(b+c) \quad (1)$$

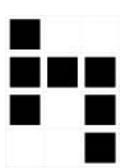
and AREA

$$\Delta = abc(a+b)(a^2-bc). \quad (2)$$

The first few integer Heronian triangles sorted by increasing maximal side lengths, are ((3, 4, 5), (5, 5, 6), (5, 5, 8), (6, 8, 10), (10, 10, 12), (5, 12, 13), (10, 13, 13), (9, 12, 15), (4, 13, 15), (13, 14, 15), (10, 10, 16), ... (Sloane's A055594, A055593, and A055592), having areas 6, 12, 12, 24, 48, 30, 60, 54, ... (Sloane's A055595). The first few integer Heronian SCALENE TRIANGLES, sorted by increasing maximal side lengths, are (3, 4, 5), (6, 8, 10), (5, 12, 13), (9, 12, 15), (4, 13, 15), (13, 14, 15), (9, 10, 17), ... (Sloane's A046128, A046129, and A046130), having areas 6, 24, 30, 54, 24, 84, 36, ... (Sloane's A046131).

Schubert (1905) claimed that Heronian triangles with two rational MEDIANS do not exist (Dickson 1952). This was shown to be incorrect by Buchholz and Rathbun (1997), who discovered the triangles given in the following table, where m_i are MEDIAN lengths and A is the area.

a	b	c	m_1	m_2	A
73	51	26	$\frac{35}{2}$	$\frac{97}{2}$	420
626	875	291	572	$\frac{433}{2}$	55440



4368	1241	3673	1657	$\frac{7975}{2}$	2042040
14791	14384	11257	$\frac{21177}{2}$	11001	75698280
28779	13816	15155	$\frac{3589}{2}$	21937	23931600
1823675	185629	1930456	$\frac{2048523}{2}$	$\frac{3751059}{2}$	142334216640

9	10	11	12
13	14	16	15

A heterosquare is an $n \times n$ ARRAY of the integers from 1 to n^2 such that the rows, columns, and diagonals have different sums. (By contrast, in a MAGIC SQUARE, they have the *same* sum.) There are no heterosquares of order two, but heterosquares of every ODD order exist. They can be constructed by placing consecutive INTEGERS in a SPIRAL pattern (Fults 1974, Madachy 1979).

An ANTIMAGIC SQUARE is a special case of a heterosquare for which the sums of rows, columns, and main diagonals form a SEQUENCE of consecutive integers.

Hex Number

The CENTERED HEXAGONAL NUMBER given by

$$H_n = 1 + 6T_n = 2H_{n-1} - H_{n-2} + 6 = 3n^2 - 3n + 1,$$

where T_n is the nth TRIANGULAR NUMBER. The first few hex numbers are 1, 7, 19, 37, 61, 91, 127, 169, ... (Sloane's A003215). The GENERATING FUNCTION of the hex numbers is

$$\frac{x(x^2+4x+1)}{(1-x)^3} = x + 7x^2 + 19x^3 + 37x^4 + \ldots.$$

The first TRIANGULAR hex numbers are 1 and 91, and the first few SQUARE ones are 1, 169, 32761, 6355441, ... (Sloane's A006051). SQUARE hex numbers are obtained by solving the DIOPHANTINE EQUATION

$$3x^2 + 1 = y^2.$$

The only hex number which is SQUARE and TRIANGULAR is 1. There are no CUBIC hex numbers.

Hexa

POLYHEX

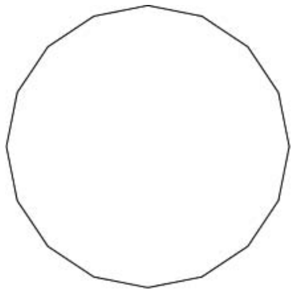
Hexabolo

A 6-POLYABOLO.

Hexacontagon

A 60-sided POLYGON.

Hexacronic Icositetrahedron



GREAT HEXACRONIC ICOSITETRAHEDRON, SMALL HEXACRONIC ICOSITETRAHEDRON

Hexad

A SET of six.

See also MONAD, QUARTET, QUINTET, TETRAD, TRIAD

Hexadecagon

A 16-sided POLYGON, sometimes also called a HEXAKAIDECAGON. The regular hexadecagon is a CONSTRUCTIBLE POLYGON, and the INRADIUS r, CIRCUMRADIUS R, and area A of the regular hexadecagon of side length 1 are

$$r = \tfrac{1}{2}(1+\sqrt{2}+\sqrt{2(2+\sqrt{2})})$$

$$R = \sqrt{\tfrac{1}{2}(4+2\sqrt{2}+\sqrt{20+14\sqrt{2}})}$$

$$A = 4(1+\sqrt{2}+\sqrt{2(2+\sqrt{2})}).$$

See also POLYGON, REGULAR POLYGON, TRIGONOMETRY VALUES PI/16

Hexadecimal

The base 16 notational system for representing REAL NUMBERS. The digits used to represent numbers using hexadecimal NOTATION are 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, and F. The following table gives the hexadecimal equivalents of the first few decimal numbers.

1	1	11	B	21	15
2	2	12	C	22	16
3	3	13	D	23	17
4	4	14	E	24	18
5	5	15	F	25	19
6	6	16	10	26	1A
7	7	17	11	27	1B
8	8	18	12	28	1C
9	9	19	13	29	1D
10	A	20	14	30	1E

The hexadecimal system is particularly important in computer programming, since four bits (each consisting of a one or zero) can be succinctly expressed using a single hexadecimal digit. Two hexadecimal digits represent numbers from 0 to 255, a common range used, for example, to specify colors. Thus, in the HTML language of the web, colors are specified using three pairs of hexadecimal digits RRGGBB, where *RR* is the amount of red, *GG* the amount of green, and *BB* the amount of blue.

In HEXADECIMAL, numbers with increasing digits are called METADROMES, those with nondecreasing digits are called PLAINDRONES, those with nonincreasing digits are called NIALPDROMES, and those with decreasing digits are called KATADROMES.

Hexafrob

POLYHEX

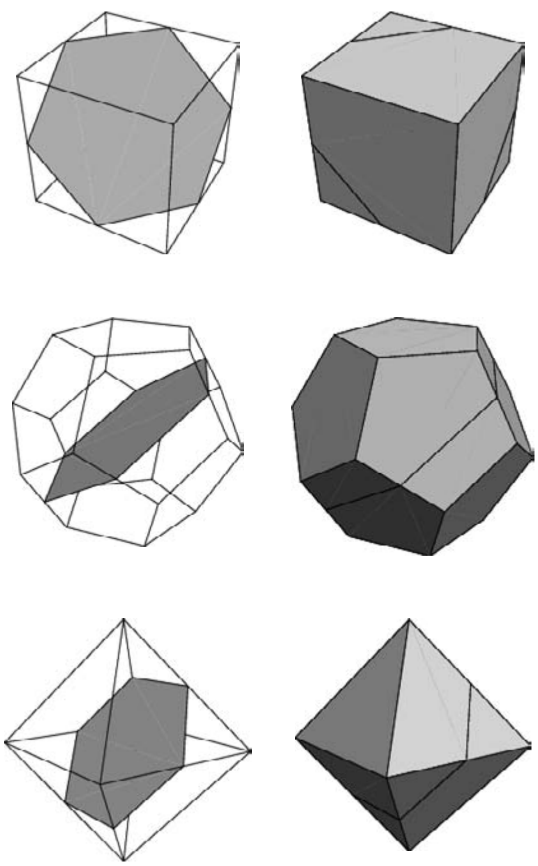
Hexagon

A six-sided POLYGON. In proposition IV.15, Euclid showed how to inscribe a regular hexagon in a CIRCLE. The INRADIUS r, CIRCUMRADIUS R, and AREA

A can be computed directly from the formulas for a general REGULAR POLYGON with side length s and $n=6$ sides,

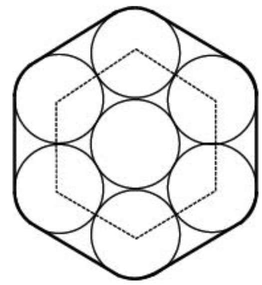
$$r=\tfrac{1}{2}s\cot\left(\frac{\pi}{6}\right)=\tfrac{1}{2}\sqrt{3}\,s \qquad (1)$$

$$R=\tfrac{1}{2}s\csc\left(\frac{\pi}{6}\right)=s \qquad (2)$$



$$A=\tfrac{1}{4}ns^2\cot\left(\frac{\pi}{6}\right)=\tfrac{3}{2}\sqrt{3}\,s^2. \qquad (3)$$

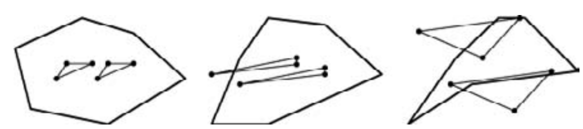
Therefore, for a regular hexagon,



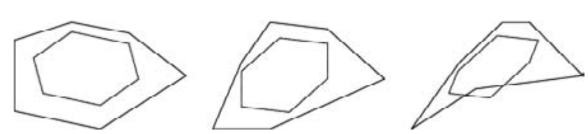
$$\frac{R}{r}=\sec\left(\frac{\pi}{6}\right)=\frac{2}{\sqrt{3}}, \qquad (4)$$

so

$$\frac{A_R}{A_r}=\left(\frac{R}{r}\right)^2=\frac{4}{3}. \qquad (5)$$



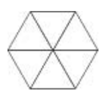
A PLANE PERPENDICULAR to a C_3 axis of a CUBE (Gardner 1960), DODECAHEDRON, or ICOSAHEDRON cuts the solid in a regular HEXAGONAL CROSS SECTION (Holden 1991, pp. 22–3 and 27). For the CUBE, the PLANE passes through the MIDPOINTS of opposite sides (Steinhaus 1983, p. 170; Cundy and Rollett 1989, p. 157; Holden 1991, pp. 22–3). Since there are four such axes for the CUBE and OCTAHEDRON, there are four possible HEXAGONAL CROSS SECTIONS. A HEXAGON is also obtained when the cube is viewed from above a corner along the extension of a space diagonal (Steinhaus 1983, p. 170).



Take seven CIRCLES and close-pack them together in a hexagonal arrangement. The PERIMETER obtained by wrapping a band around the CIRCLE then consists of six straight segments of length d (where d is the DIAMETER) and 6 arcs with total length 1/6 of a CIRCLE. The PERIMETER is therefore

$$p=(12+2\pi)r=2(6+\pi)r. \qquad (6)$$

Given an arbitrary hexagon, take each three consecutive vertices, and mark the fourth point of the PARALLELOGRAM sharing these three vertices. Taking alternate points then gives two congruent triangles, as illustrated above (Wells 1991).



Given an arbitrary hexagon, connecting the centroids of each consecutive three sides gives a hexagon with equal and parallel sides known as the CENTROID HEXAGON (Wells 1991).

Hexagon Tiling

There are at least three aperiodic tilings of HEXAGONS, given by the following types:

$$\begin{array}{ll} A+B+C=360^\circ & a=d \\ A+B+D=360^\circ & a=d,\ c=e \\ A=C=E & a=b,\ c=d,\ e=f \end{array} \quad (1)$$

(Gardner 1988). Note that the periodic hexagonal TESSELLATION is a degenerate case of all three tilings with

$$A=B=C=D=E=F \quad a=b=c=d=e=f \quad (2)$$

Amazingly, the number of PLANE PARTITIONS $PL(a, b, c)$ contained in an $a \times b \times c$ box also gives the number of hexagon tilings by RHOMBI for a hexagon of side lengths a, b, c, a, b, c (David and Tomei 1989, Fulmek and Krattenthaler 2000). The asymptotic distribution of rhombi in a random hexagon tiling by rhombi was given by Cohn *et al.* (1998). A variety of enumerations for various explicit positions of rhombi are given by Fulmek and Krattenthaler (1998, 2000).

Hexagonal Close Packing

SPHERE PACKING

Hexagonal Number

A FIGURATE NUMBER and 6-POLYGONAL NUMBER OF THE FORM $n(2n-1)$. The first few are 1, 6, 15, 28, 45,

... (Sloane's A000384). The GENERATING FUNCTION of the hexagonal numbers

$$\frac{x(3x+1)}{(1-x)^3} = x + 6x^2 + 15x^3 + 28x^4 + \ldots.$$

Every hexagonal number is a TRIANGULAR NUMBER since

$$r(2r-1) = \tfrac{1}{2}(2r-1)[(2r-1)+1].$$

In 1830, Legendre (1979) proved that every number larger than 1791 is a sum of four hexagonal numbers, and Duke and Schulze-Pillot (1990) improved this to three hexagonal numbers for every sufficiently large integer. The numbers 11 and 26 can only be REPRESENTED AS a sum using the maximum possible of six hexagonal numbers:

$$11 = 1+1+1+1+1+6$$

$$26 = 1+1+6+6+6+6.$$

See also FIGURATE NUMBER, HEX NUMBER, HEPTAGONAL HEXAGONAL NUMBER, HEXAGONAL PENTAGONAL NUMBER, OCTAGONAL HEXAGONAL NUMBER, TRIANGULAR NUMBER

Hexagonal Pentagonal Number

A number which is simultaneously PENTAGONAL and HEXAGONAL. Let P_n denote the nth PENTAGONAL NUMBER and H_m the mth SQUARE NUMBER, then a number which is both pentagonal and hexagonal satisfies the equation $P_n = H_m$, or

$$\tfrac{1}{2}n(3n-1) = m(2m-1). \tag{1}$$

COMPLETING THE SQUARE and rearranging gives

$$(6n-1)^2 - 3(4m-1)^2 = -2. \tag{2}$$

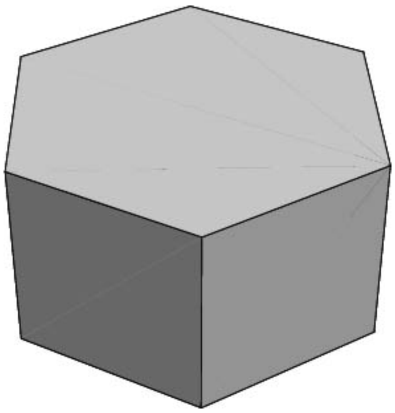
Therefore, defining

$$x \equiv 2n+1 \tag{3}$$

$$y \equiv 2m \tag{4}$$

gives the Pell-like equation

$$x^2 - 3y^2 = -2 \tag{5}$$



The first few solutions are $(x, y) = (1, 1)$, (5, 3), (19, 11), (71, 74), (265, 153), (989, 571), ... These give the solutions (n, m), (1, 1), (10/3, 3), (12, 21/2), (133/3, 77/2), (165, 143), ..., of which the integer solutions are (1, 1), (165, 143), (31977, 27693), (6203341, 5372251), ... (Sloane's A046178 and A046179), corresponding to the pentagonal hexagonal numbers 1, 40755, 1533776805, 57722156241751, ... (Sloane's A046180).

Hexagonal Prism

A PRISM composed of hexagonal faces. The regular right hexagonal prism has SURFACE AREA and VOLUME

$$S = 3(2+\sqrt{3})$$

$$V = \tfrac{3}{2}\sqrt{3}.$$

See also HEXAGON, PRISM

Hexagonal Pyramid

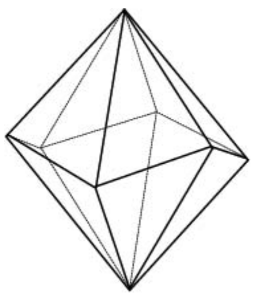
A PYRAMID with a hexagonal base. The SLANT HEIGHT of a hexagonal pyramid is a special case of the formula for a regular n-gonal PYRAMID with $n = 6$, given by

$$s = \sqrt{h^2 + a^2}, \tag{1}$$

where h is the height and a is the length of a side of the base.

See also HEXAGON, PYRAMID

Hexagonal Pyramidal Number



A PYRAMIDAL NUMBER OF THE FORM $n(n+1)(4n-1)/6$, The first few are 1, 7, 22, 50, 95, ... (Sloane's A002412). The GENERATING FUNCTION of the hexagonal pyramidal numbers is

$$\frac{x(3x+1)}{(x-1)^4}=x+7x^2+22x^3+50x^4+\ldots.$$

Cotton, F. A. *Chemical Applications of Group Theory, 3rd ed.* New York: Wiley, p. 63, 1990.

Hexagonal Square Number

Let H_n denote the nth HEXAGONAL NUMBER and S_m the mth SQUARE NUMBER, then a number which is both hexagonal and square satisfies the equation $H_n = S_m$, or

$$n(2n-1)=m^2. \quad (1)$$

COMPLETING THE SQUARE and rearranging gives

$$(4n-1)^2-8m^2=1. \quad (2)$$

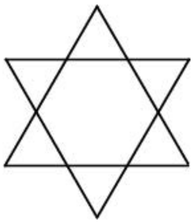
Therefore, defining

$$x\equiv 4n-1 \quad (3)$$

$$y\equiv 2m \quad (4)$$

gives the PELL EQUATION

$$x^2-2y^2=1. \quad (5)$$



The first few solutions are $(x, y)=(3, 2)$, (17, 12), (99, 70), (577, 408), ... These give the solutions $(n, m)=(1, 1)$, (9/2, 6), (25, 35), (289/2, 204), ..., giving the integer solutions (1, 1), (25, 35), (841, 1189), (28561, 40391), ... (Sloane's A008844 and A046176). The corresponding hexagonal square numbers are 1, 1225, 1413721, 1631432881, 1882672131025, ... (Sloane's A046177).

Hexiamond Tiling

There are a number of tilings of various shapes by *all* the 12 order $n = 6$ polyiamonds, summarized in the following table. Several of these (starred in the table below) are also illustrated above (Beeler 1972). Beeler's numbers for the side 6 parallelogram of base 6 and side 4 trapezoid (156 and 76, respectively), differ from those quoted in Gardner (1984, p. 182) of 155 and 74, respectively.

Size	Solutions
side 9 Δ with inverted side 3 Δ hole	0
side 6 trapezoid with bases 3 and 9	0
two side 6 triangles	0
3×12 rhomboid	0
4×9 rhomboid*	37
side 4 trapezoid with bases 7 and 11*	76
side 6 parallelogram of base 6*	156
triangle of side 9 with 1, 2, 2 corners removed*	5885
trefoil*	several

The following table gives the number of solutions to various hexiamond tilings using fewer than 12 pieces. Those indicated with asterisks (*) have a solution illustrated above.

Size	Pieces	Solutions
2-hexagon		≥ 1
3-hexagon*	9	≥ 15
equilateral Δ		0
hexagonal ring		0
6-point star*	8	1
triangular ring		0
2×3 rhomboid		0
2×6 rhomboid*	4	1
3×3 rhomboid	3	0
3×4 rhomboid	4	many
3×5 rhomboid	5	many

Hexlet

Consider two mutually tangent (externally) spheres A and B together with a larger sphere C inside which A and B are internally tangent. Then construct a chain of spheres each tangent externally to A, B and internally to C (so that C encloses the chain as well as the two original spheres). Surprisingly, every such chain closes into a "necklace" after six spheres, regardless of where the first sphere is placed.

This beautiful and amazing result due to Soddy (1937) is a special case of Kollros' Theorem. It can be demonstrated using inversion of six identical spheres around an equal center sphere, all of which are sandwiched between two planes (Wells 1991, pp. 120 and 232). This result was given in a Sangaku problem from Kanagawa Prefecture in 1822, more than a century before it was published by Soddy (Rothman 1998).

Moreover, the centers of the six spheres in the necklace and their six points of contact all lie in a plane. Furthermore, there are two planes which touch each of the six spheres, one on either side of the necklace. Finally, the radii r_i of the spheres are related by

$$\frac{1}{r_1}+\frac{1}{r_4}=\frac{1}{r_2}+\frac{1}{r_3}=\frac{1}{r_3}+\frac{1}{r_6}$$

(Rothman 1998).

Soddy's bowl of integers contains an infinite number of nested hexlets. The centers of a Soddy hexlet always lie on an ellipse (Ogilvy 1990, p. 63).

H-Function

FOX'S H-FUNCTION

Hh Function

Let

$$Z(x) \equiv \frac{1}{\sqrt{2\pi}}\, e^{-x^2/2} \tag{1}$$

$$Q(x) \equiv \frac{1}{\sqrt{2\pi}} \int_x^\infty e^{-t^2/2}\, dt \tag{2}$$

$$= \frac{1}{2}\left[1 - \operatorname{erf}\left(\frac{x}{\sqrt{2}}\right)\right], \tag{3}$$

where $Z(x)$ and $Q(x)$ are closely related to the NORMAL DISTRIBUTION FUNCTION, then

$$\mathrm{Hh}_{-n}(x) = (-1)^{n-1}\, \sqrt{2\pi}\, Z^{(n-1)}(x) \tag{4}$$

$$\mathrm{Hh}_n(x) = \frac{(-1)^n}{n!}\, \mathrm{Hh}_{-1}(x)\, \frac{d^n}{dx^n}\left[\frac{Q(x)}{Z(x)}\right]. \tag{5}$$

The first few values are

$$\mathrm{Hh}_{-3}(x) = e^{-x^2/2}(x^2 - 1) \tag{6}$$

$$\mathrm{Hh}_{-2}(x) = e^{-x^2/2}x \tag{7}$$

$$\mathrm{Hh}_{-1}(x) = e^{-x^2/2} \tag{8}$$

$$\mathrm{Hh}_0(x) = 0 \tag{9}$$

$$\mathrm{Hh}_1(x) = e^{-x^2/2} - \sqrt{\frac{\pi}{2}}\, x \operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right) \tag{10}$$

$$\mathrm{Hh}_2(x) = \frac{1}{4}\left[-2xe^{-x^2/2} + \sqrt{2\pi}(x^2+1)\operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right)\right] \tag{11}$$

$$\mathrm{Hh}_3(x) = \frac{1}{12}\left[2e^{-x^2/2}(x^2+2) - \sqrt{2\pi}\, x(x^2+3)\operatorname{erfc}\left(\frac{x}{\sqrt{2}}\right)\right]. \tag{12}$$

Highly Abundant Number

HIGHLY COMPOSITE NUMBER

Highly Composite Number

A COMPOSITE NUMBER (also called a SUPERABUNDANT NUMBER) is a number n which has more FACTORS than any other number less than n. In other words, $\sigma(n)/n$ exceeds $\sigma(k)/k$ for all $k<n$, where $\sigma(n)$ is the DIVISOR FUNCTION. They were called highly composite numbers by Ramanujan, who found the first 100 or so, and superabundant numbers by Alaoglu and Erdos (1944).

There are an infinite number of highly composite numbers, and the first few are 2, 4, 6, 12, 24, 36, 48, 60, 120, 180, 240, 360, 720, 840, 1260, 1680, 2520, 5040, ... (Sloane's A002182). Ramanujan (1915) listed 102 up to 6746328388800 (but omitted 293, 318, 625, 600, and 29331862500). Robin (1983) gives the first 5000 highly composite numbers, and a comprehensive survey is given by Nicholas (1988).

If

$$N = 2^{a_2} 3^{a_3} \cdots p^{a_p} \tag{1}$$

is the PRIME FACTORIZATION of a highly composite number, then

1. The PRIMES 2, 3, ..., p form a string of consecutive PRIMES,
2. The exponents are nonincreasing, so $a_2 \geq a_3 \geq \ldots \geq a_p$, and
3. The final exponent a_p is always 1, except for the two cases $N=4=2^2$ and $N=36=2^2\cdot 3^2$, where it is 2.

Let $Q(x)$ be the number of highly composite numbers $\leq x$. Ramanujan (1915) showed that

$$\lim_{x\to\infty} \frac{Q(x)}{\ln x} = \infty. \tag{2}$$

Erdos (1944) showed that there exists a constant $c_1>0$ such that

$$Q(x) \geq (\ln x)^{1+c_1} \tag{3}$$

Nicholas proved that there exists a constant $c_2>0$ such that

$$Q(x) \ll (\ln x)^{c_2}. \tag{4}$$

Hilbert Basis

A Hilbert basis for the VECTOR SPACE of square summable sequences $(a_n)=a_1,\ a_2,\ \ldots$ is given by the standard basis e_i, where $e_i=\delta_{in}$, with δ_{in} the KRONECKER DELTA. Then

$$(a_n) = \sum a_i e_i,$$

with $\Sigma |a_i|^2 < \infty$. Although strictly speaking, the e_i are not a BASIS because there exist elements which are not a finite LINEAR COMBINATION, they are given the special term "Hilbert basis."

In general, a HILBERT SPACE V has a Hilbert basis e_i if the e_i are an ORTHONORMAL BASIS and every element $v \in V$ can be written

$$v = \sum_{i=1}^{\infty} a_i e_i$$

for some a_i with $\Sigma |a_i|^2 < \infty$.

Hilbert Curve

A LINDENMAYER SYSTEM invented by Hilbert (1891) whose limit is a PLANE-FILLING CURVE which fills a square. Traversing the VERTICES of an n-D HYPERCUBE in GRAY CODE order produces a generator for the n-D Hilbert curve (Goetz). The Hilbert curve can be simply encoded with initial string "L", STRING REWRITING rules "L" -> "+RF-LFL-FR+RFR+FL-", and angle 90° (Peitgen and Saupe 1988, p. 278).

A related curve is the Hilbert II curve, shown above (Peitgen and Saupe 1988, p. 284). It is also a LINDENMAYER SYSTEM and the curve can be encoded with initial string "X", STRING REWRITING rules "X" -> "XFYFX+F+YFXFY-F-XFYFX", "Y" -> "YFX-FY-F-XFYFX+F+YFXFY", and angle 90°.

Hilbert Function

Let $\Gamma = \{p_1, \ldots, p_m\} \subset \mathbb{P}^2$ be a collection of m distinct points. Then the number of conditions imposed by Γ on forms of degree d is called the Hilbert function h_Γ of Γ. If curves X_1 and X_2 of degrees d and e meet in a collection Γ of $d \cdot e$ points, then for any k, the number $h_\Gamma(k)$ of conditions imposed by Γ on forms of degree k is independent of X_1 and X_2 and is given by

$$h_\Gamma(k) = \binom{k+2}{2} - \binom{k-d+2}{2} - \binom{k-e+2}{2} + \binom{k-d-e+2}{2},$$

where the BINOMIAL COEFFICIENT $\binom{a}{2}$ is taken as 0 if $a < 2$ (Cayley 1843).

Hilbert Matrix

A MATRIX H with elements

$$H_{ij} \equiv (i+j-1)^{-1}$$

for $i, j = 1, 2, ..., n$. Hilbert matrices are given by `HilbertMatrix[m, n]` in the *Mathematica* add-on package `LinearAlgebra'MatrixManipulation'` (which can be loaded with the command `<<LinearAlgebra'`). Although the MATRIX INVERSE is given analytically by

$$(H^{-1})_{ij} = \frac{(-1)^{i+j}}{i+j-1}\frac{(n+i-1)!(n+j-1)!}{[(i-1)!(j-1)!]^2(n-i)!(n-j)!},$$

Hilbert matrices are difficult to invert numerically. The DETERMINANTS for the first few values of H_n are given in the following table, and the numerical values for $n = 1, 2, ...$ are given by one divided by 1, 12, 2160, 6048000, 266716800000, ... (Sloane's A005249).

n	det(H)
1	1
2	8.33333×10^{-2}
3	4.62963×10^{-4}
4	1.65344×10^{-7}
5	3.74930×10^{-12}
6	5.36730×10^{-18}

Hilbert Number

GELFOND-SCHNEIDER CONSTANT

Hilbert Polynomial

Let Γ be an ALGEBRAIC CURVE in a projective space of DIMENSION n, and let p be the PRIME IDEAL defining Γ, and let $\chi(p, m)$ be the number of linearly independent forms of degree m modulo p. For large m, $\chi(p, m)$ is a POLYNOMIAL known as the Hilbert polynomial.

References

Iyanaga, S. and Kawada, Y. (Eds.). *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, p. 36, 1980.

Hilbert Space

A Hilbert space is a VECTOR SPACE H with an INNER PRODUCT $\langle f, g\rangle$ such that the NORM defined by

$$|f| = \sqrt{\langle f, f\rangle}$$

turns H into a COMPLETE METRIC SPACE. If the INNER PRODUCT does not so define a NORM, it is instead known as an INNER PRODUCT SPACE.

Examples of FINITE-dimensional Hilbert spaces include

1. The REAL NUMBERS $\mathbb{R}^n$ with $\langle v, u\rangle$ the vector DOT PRODUCT of v and u.
2. The COMPLEX NUMBERS $\mathbb{C}^n$ with $\langle v, u\rangle$ the vector DOT PRODUCT of v and the COMPLEX CONJUGATE of u.

An example of an INFINITE-dimensional Hilbert space is L^2, the SET of all FUNCTIONS $f : \mathbb{R} \to \mathbb{R}$ such that the INTEGRAL of f^2 over the whole REAL LINE is FINITE. In this case, the INNER PRODUCT is

$$\langle f, g\rangle = \int_{-\infty}^{\infty} f(x)g(x)\,dx.$$

A Hilbert space is always a BANACH SPACE, but the converse need not hold.

See also BANACH SPACE, COMPLETE SET OF FUNCTIONS, HILBERT BASIS, L2-NORM, L2-SPACE, LIOUVILLE SPACE, PARALLELOGRAM LAW, VECTOR SPACE

Hilbert Symbol

For any two nonzero P-ADIC NUMBERS a and b, the Hilbert symbol is defined as

$$(a, b) = \begin{cases} 1 & \text{if } z^2 = ax^2 + by^2 \text{ has a nonzero solution} \\ -1 & \text{otherwise.} \end{cases}$$

If the p-adic field is not clear, it is said to be the

Hilbert symbol of a and b relative to k. The field can also be the reals ($p = \infty$). The Hilbert symbol satisfies the following formulas:

1. $(a, b) = (b, a)$.
2. $(a, c^2) = 1$ for any c.
3. $(a, -a) = 1$.
4. $(a, 1 - a) = 1$.
5. $(a, b) = 1 \Rightarrow (aa', b) = (a', b)$.
6. $(a, b) = (a, -ab) = (a, (1 - a)b)$.

The Hilbert symbol depends only the values of a and b modulo squares. So the symbol is a map $k^*/k^{*2} \times k^*/k^{*2} \to \{1, -1\}$.

Hilbert showed that for any two nonzero rational numbers a and b,

1. $(a, b)_v = 1$ for almost every prime v.
2. $\prod (a, b)_v = 1$ where v ranges over every prime, including $v = \infty$ corresponding to the reals.

Hilbert Transform

The INTEGRAL TRANSFORM

$$g(y) = \mathscr{H}[f(x)] = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{f(x)\,dx}{x - y}$$

$$f(x) = \mathscr{H}^{-1}[g(y)] = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{g(y)\,dy}{y - x},$$

where the CAUCHY PRINCIPAL VALUE is taken in each of the integrals.

In the following table, $\Pi(x)$ is the RECTANGLE FUNCTION, $\operatorname{sinc} x$ is the SINC FUNCTION, $\delta(x)$ is the DELTA FUNCTION, $\Pi(x)$ and $I_I(x)$ are IMPULSE SYMBOLS, and ${}_1F_1(a; b; x)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND.

$f(x)$	$g(y)$
$\sin x$	$\cos y$
$\cos x$	$-\sin y$
$\frac{\sin x}{x}$	$\frac{\cos y - 1}{y}$
$\Pi(x)$	$\frac{1}{\pi} \ln\left\lvert\frac{y - \frac{1}{2}}{y + \frac{1}{2}}\right\rvert$
$\frac{1}{1 + x^2}$	$-\frac{y}{1 + y^2}$
$\operatorname{sinc}' x$	$-\pi \operatorname{sinc} y - \frac{1}{2}\pi \operatorname{sinc}^2(\frac{1}{2}\pi y)$
$\delta(x)$	$-\frac{1}{\pi y}$
$\Pi(x)$	$\frac{y}{\pi(\frac{1}{4} - y^2)}$
$I_I(x)$	$-\frac{1}{2\pi(\frac{1}{4} - y^2)}$
e^{-x^2}	$-\frac{2y}{\sqrt{\pi}}\, {}_1F_1(a; b; x)$

Hilbert's Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Extend HILBERT'S INEQUALITY by letting $p,\ q > 1$ and

$$\frac{1}{p}+\frac{1}{q}\geq 1, \qquad (1)$$

so that

$$0 < \lambda = 2-\frac{1}{p}-\frac{1}{q}\leq 1. \qquad (2)$$

Levin (1937) and Steckin (1949) showed that

$$\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\frac{a_m b_n}{(m+n)^\lambda} \leq \left\{\pi\csc\left[\frac{\pi(q-1)}{\lambda q}\right]\right\}^\lambda \left[\sum_{m=1}^{\infty}(a_m)^p\right]^{1/p}\left[\sum_{n=1}^{\infty}(a_n)^q\right]^{1/q} \qquad (3)$$

and

$$\int_0^\infty\int_0^\infty \frac{f(x)g(y)}{(x+y)^\lambda}\,dx\,dy < \pi\csc\left[\frac{\pi(q-1)}{p}\right]^\lambda \times\left(\int_0^\infty [f(x)]^p\,dx\right)^{1/p}\left(\int_0^\infty [g(x)]^q\,dx\right)^{1/q}. \qquad (4)$$

Mitrinovic *et al.* (1991) indicate that this constant is the best possible.

Hilbert's Inequality

Given a POSITIVE SEQUENCE $\{a_n\}$,

$$\sqrt{\sum_{j=-\infty}^{\infty}\left|\sum_{\substack{n=-\infty\\ n\neq j}}^{\infty}\frac{a_n}{j-n}\right|^2}\leq \pi\sqrt{\sum_{n=-\infty}^{\infty}|a_n|^2},$$

where the a_ns are REAL and "square summable."

Another INEQUALITY known as Hilbert's applies to NONNEGATIVE sequences $\{a_n\}$ and $\{b_n\}$,

$$\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\frac{a_m b_n}{m+n} < \pi\csc\left(\frac{\pi}{p}\right)\left(\sum_{m=1}^{\infty}a_m^p\right)^{1/p}\left(\sum_{n=1}^{\infty}b_n^q\right)^{1/q}$$

unless all a_n or all b_n are 0. If $f(x)$ and $g(x)$ are NONNEGATIVE integrable functions, then the integral form is

$$\int_0^\infty\int_0^\infty \frac{f(x)g(y)}{x+y}\,dx\,dy < \pi\csc\left(\frac{\pi}{p}\right) \times\left(\int_0^\infty [f(x)]^p\,dx\right)^{1/p}\left(\int_0^\infty [g(x)]^q\,dx\right)^{1/q}.$$

The constant $\pi\csc(\pi/P)$ is the best possible, in the sense that counterexamples can be constructed for any smaller value.

Hilbert's Nullstellensatz

Let K be an algebraically closed field and let $\mathfrak{I}$ be an IDEAL in $K(x)$, where $x(x_1, x_2, \ldots, x_n$ is a finite set of indeterminates. Let $p\in K(x)$ be such that for any $(c_1, \ldots, c_n$ in K^n, if every element of $\mathfrak{J}$ vanishes when evaluated if we set each $(x_i = c_i)$, then p also vanishes. Then p^i lies in $\mathfrak{I}$ for some j. Colloquially, the theory of algebraically closed fields is a complete model.

Hilbert's Problems

A set of (originally) unsolved problems in mathematics proposed by Hilbert. Of the 23 total, ten were presented at the Second International Congress in Paris in 1900. These problems were designed to serve as examples for the kinds of problems whose solutions would lead to the furthering of disciplines in mathematics.

1a. Is there a transfinite number between that of a DENUMERABLE SET and the numbers of the CONTINUUM? This question was answered by Gödel and Cohen to the effect that the answer depends on the particular version of SET THEORY assumed.
1b. Can the CONTINUUM of numbers be considered a WELL ORDERED SET? This question is related to Zermelo's AXIOM OF CHOICE. In 1963, the AXIOM OF CHOICE was demonstrated to be independent of all other AXIOMS in SET THEORY, so there appears to be

no universally valid solution to this question either.
2. Can it be proven that the AXIOMS of logic are consistent? GÖDEL'S INCOMPLETENESS THEOREM indicated that the answer is "no," in the sense that any formal system interesting enough to formulate its own consistency can prove its own consistency IFF it is inconsistent.
3. Give two TETRAHEDRA which cannot be decomposed into congruent TETRAHEDRA directly or by adjoining congruent TETRAHEDRA. Max Dehn showed this could not be done in 1902 by inventing the theory of DEHN INVARIANTS, and W. F. Kagon obtained the same result independently in 1903.
4. Find GEOMETRIES whose AXIOMS are closest to those of EUCLIDEAN GEOMETRY if the ORDERING and INCIDENCE AXIOMS are retained, the CONGRUENCE AXIOMS weakened, and the equivalent of the PARALLEL POSTULATE omitted. This problem was solved by G. Hamel.
5. Can the assumption of differentiability for functions defining a continuous transformation GROUP be avoided? (This is a generalization of the CAUCHY FUNCTIONAL EQUATION.) Solved by John von Neumann in 1930 for bicompact groups. Also solved for the ABELIAN case, and for the solvable case in 1952 with complementary results by Montgomery and Zipin (subsequently combined by Yamabe in 1953). Andrew Glean showed in 1952 that the answer is also "yes" for all locally bicompact groups.
6. Can physics be axiomized?
7. Let $\alpha \neq 1 \neq 0$ be ALGEBRAIC and β IRRATIONAL. Is α^β then TRANSCENDENTAL (Wells 1986, p. 45)? α^β is known to be transcendental for the special case of β an ALGEBRAIC NUMBER, as proved in 1934 by Aleksander Gelfond in a result now known as GELFOND'S THEOREM (Courant and Robins 1996). However, the case of general irrational β has not been resolved.
8. Prove the RIEMANN HYPOTHESIS. The CONJECTURE has still been neither proved nor disproved.
9. Construct generalizations of the RECIPROCITY THEOREM of NUMBER THEORY.
10. Does there exist a universal algorithm for solving DIOPHANTINE EQUATIONS? The impossibility of obtaining a general solution was proven by Julia Robinson and Martin Davis in 1970, following proof of the result that the relation $n = F_{2m}$ (where F_{2m} is a FIBONACCI NUMBER) is Diophantine by Yuri Matijasevich (Matiyasevich 1970; Davis 1973; Davis and Hersh 1973; Davis 1982; Matiyasevich 1993; Reid 1997, p. 107). More specifically, Matiyasevich showed that there is a polynomial P in n, m, and a number of other variables $x, y, z, \ldots$ having the property that $n = F_{2m}$ IFF there exist integers $x, y, z, \ldots$ such that $P(n, m, x, y, z, \ldots) = 0$.
11. Extend the results obtained for quadratic fields to arbitrary INTEGER algebraic fields.
12. Extend a theorem of Kronecker to arbitrary algebraic fields by explicitly constructing Hilbert class fields using special values. This calls for the construction of HOLOMORPHIC FUNCTIONS in several variables which have properties analogous to the exponential function and elliptic modular functions (Holzapfel 1995).
13. Show the impossibility of solving the general seventh degree equation by functions of two variables.
14. Show the finiteness of systems of relatively integral functions.
15. Justify Schubert's ENUMERATIVE GEOMETRY (Bell 1945).
16. Develop a topology of real algebraic curves and surfaces. The TANIYAMA-SHIMURA CONJECTURE postulates just this connection. See Gudkov and Utkin (1978), Ilyashenko and Yakovenko (1995), and Smale (2000).
17. Find a representation of definite form by SQUARES.
18. Build spaces with congruent POLYHEDRA.
19. Analyze the analytic character of solutions to variational problems.
20. Solve general BOUNDARY VALUE PROBLEMS.
21. Solve differential equations given a MONODROMY GROUP. More technically, prove that there always exists a FUCHSIAN SYSTEM with given singularities and a given MONODROMY GROUP. Several special cases had been solved, but a NEGATIVE solution was found in 1989 by B. Bolibruch (Anasov and Bolibruch 1994).
22. Uniformization.
23. Extend the methods of CALCULUS OF VARIATIONS.

Hill Determinant

A DETERMINANT which arises in the solution of the second-order ORDINARY DIFFERENTIAL EQUATION

$$x^2 \frac{d^2\psi}{dx^2} + x\frac{d\psi}{dx} + \left(\tfrac{1}{4}h^2x^2 + \tfrac{1}{2}h^2 - b + \frac{h^2}{4x^2}\right)\psi = 0. \quad (1)$$

Writing the solution as a POWER SERIES

$$\psi = \sum_{n=-\infty}^{\infty} a_n x^{s+2n} \quad (2)$$

gives a RECURRENCE RELATION

$$h^2 a_{n+1} + [2h^2 - 4b + 16(n + \tfrac{1}{2}s)^2]a_n + h^2 a_{n-1} = 0. \quad (3)$$

The value of s can be computed using the Hill determinant

$$\Delta(s) = \begin{vmatrix} \ddots & \vdots & \vdots & \vdots & \vdots & ⋰ \\ \cdots & \frac{(\sigma+2)-\alpha^2}{4-\alpha^2} & \frac{\beta^2}{4-\alpha^2} & 0 & 0 & \cdots \\ \cdots & 0 & -\frac{\beta^2}{\alpha^2} & -\frac{\sigma^2-\alpha^2}{\alpha^2} & -\frac{\beta^2}{\alpha^2} & \cdots \\ \cdots & 0 & 0 & -\frac{\beta^2}{1-\alpha^2} & \frac{(\sigma-1)^2-\alpha^2}{1-\alpha^2} & \cdots \\ ⋰ & \vdots & \vdots & \vdots & \vdots & \ddots \end{vmatrix} \quad (4)$$

where

$$\sigma = \tfrac{1}{2}s \quad (5)$$

$$\alpha^2 = \tfrac{1}{4}b - \tfrac{1}{8}h^2 \quad (6)$$

$$\beta = \tfrac{1}{4}h, \quad (7)$$

and σ is the variable to solve for. The determinant can be given explicitly by the amazing formula

$$\Delta(s) = \Delta(0) - \frac{\sin^2(\pi s/2)}{\sin^2\left(\frac{1}{2}\pi\sqrt{b - \frac{1}{2}h^2}\right)}, \quad (8)$$

where

$$\Delta(0) = \begin{vmatrix} \ddots & \vdots & \vdots & \vdots & \vdots & \cdot^{\cdot^{\cdot}} \\ \cdots & 1 & \frac{h^2}{144+2h^2-4b} & 0 & 0 & \cdots \\ \cdots & \frac{h^2}{64+2h^2-4b} & 1 & \frac{h^2}{64+2h^2-4b} & 0 & \cdots \\ \cdots & 0 & \frac{h^2}{16+2h^2-4b} & 1 & \frac{h^2}{16+2h^2-4b} & \cdots \\ \cdots & 0 & 0 & \frac{h^2}{2h^2-4b} & 1 & \cdots \\ \cdots & 0 & 0 & 0 & \frac{h^2}{16+2h^2-4b} & \ddots \\ \cdot^{\cdot^{\cdot}} & \vdots & \vdots & \vdots & & \end{vmatrix} \tag{9}$$

leading to the implicit equation for s,

$$\sin^2\left(\tfrac{1}{2}\pi s\right) = \Delta(0)\sin^2\left(\tfrac{1}{2}\pi\sqrt{b - \tfrac{1}{2}h^2}\right). \tag{10}$$

Hill's Differential Equation

The second-order ordinary differential equation

$$\frac{d^2y}{dx^2} + \left[\theta_0 + 2\sum_{n=1}^{\infty}\theta_n\cos(2nx)\right]y = 0, \tag{1}$$

where θ_n are fixed constants. A general solution can be given by taking the "determinant" of an infinite matrix.

If only the $n = 0$ term is present, the equation have solution

$$y = C_1\sin(x\sqrt{\theta_0}) + C_2\cos(x\sqrt{\theta_0}). \tag{2}$$

If terms $n \leq 1$ are included, the equation becomes the Mathieu differential equation, which has solution

$$y = C_1 C(a, -\tfrac{1}{2}b, x) + C_2 S\left(a, -\tfrac{1}{2}b, x\right). \tag{3}$$

If terms $n \leq 2$ are included, it becomes the Whittaker-Hill differential equation.

Hillam's Theorem

If $f : [a, b] \to [a, b]$ (where $[a, b]$ denotes the closed interval from a to b on the real line) satisfies a Lipschitz condition with constant K, i.e., if

$$|f(x) - f(y)| \leq K|x - y|$$

for all $x, y \in [a, b]$, then the iteration scheme

$$x_{n+1} = (1 - \lambda)x_n + \lambda f(x_n),$$

where $\lambda = 1/(K + 1)$, converges to a fixed point of f.

Hindu Check

Casting Out Nines

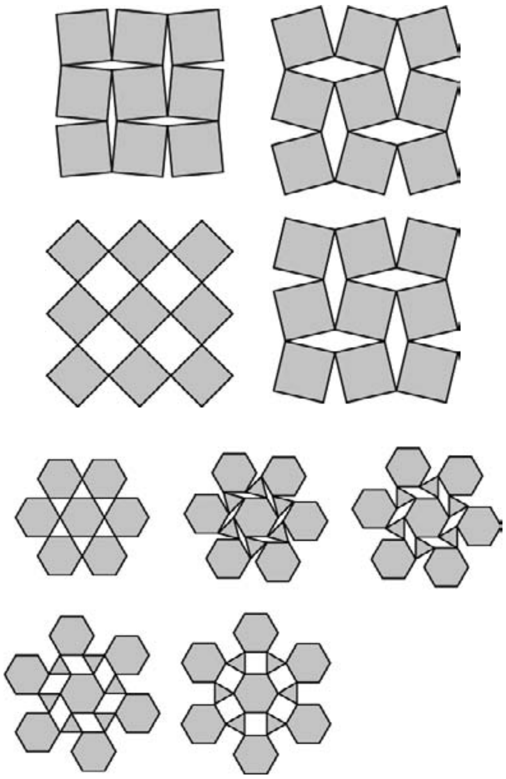
Hinge

The upper and lower hinges are descriptive statistics of a set of N data values, where N is of the form $N = 4n + 5$ with $n = 0, 1, 2, \ldots$. The hinges are obtained by ordering the data in increasing order $a_1, \ldots, a_N$, and writing them out in the shape of a "w" as illustrated above. The values at the bottom legs are called the hinges H_1 and H_2 (and the central peak is the median). In this ordering,

$$H_1 = a_{n+2} = a_{(N+3)/4}$$

$$M = a_{2n+3} = a_{(N+1)/2}$$

$$H_2 = a_{3n+4} = a_{(3N+1)/4}.$$



For N of the form $4n + 5$, the hinges are identical to the quartiles. The difference $H_2 - H_1$ is called the H-spread.

Hi-Q

A triangular version of PEG SOLITAIRE with 15 holes and 14 pegs. Numbering hole 1 at the apex of the triangle and thereafter from left to right on the next lower row, etc., the following table gives possible ending holes for a single peg removed (Beeler 1972). Because of symmetry, only the first five pegs need be considered. Also because of symmetry, removing peg 2 is equivalent to removing peg 3 and flipping the board horizontally.

remove	possible ending pegs
1	1, 7 = 10, 13
2	2, 6, 11, 14
4	3 = 12, 4, 9, 15
5	13

Histogram

The grouping of data into BINS (spaced apart by the so-called CLASS INTERVAL) plotting the number of members in each bin versus the bin number. The above histogram shows the number of variates in bins with CLASS INTERVAL 1 for a sample of 100 real variates with a UNIFORM DISTRIBUTION from 0 and 10. Therefore, bin 1 gives the number of variates in the range 0–, bin 2 gives the number of variates in the range 1–, etc.

Hitting Set

VERTEX COVER

Hjelmslev's Theorem

When all the points P on one line are related by an ISOMETRY to all points P' on another, the MIDPOINTS of the segments PP' are either distinct and COLLINEAR or COINCIDENT.

HJLS Algorithm

An algorithm for finding INTEGER RELATIONS whose running time is bounded by a polynomial in the number of real variables (Ferguson and Bailey 1992). Unfortunately, it is numerically unstable and therefore requires extremely high numeric precision. The cause of this instability is not known, but is believed to derive from its reliance on GRAM-SCHMIDT ORTHONORMALIZATION (Ferguson and Bailey 1992), which is known to be numerically unstable (Golub and van Loan 1989).

Rössner, C. and Schnorr (1994) have developed a stable variation of HJLS (Ferguson *et al.* 1999).

Hoehn's Theorem

A geometric theorem related to the PENTAGRAM and also called the PRATT-KASAPI THEOREM.

$$\frac{|V_1W_1|}{|W_2V_3|}\frac{|V_2W_2|}{|W_3V_4|}\frac{|V_3W_3|}{|W_4V_5|}\frac{|V_4W_4|}{|W_5V_1|}\frac{|V_5W_5|}{|W_1V_2|} = 1$$

$$\frac{|V_1W_2|}{|W_1V_3|}\frac{|V_2W_3|}{|W_2V_4|}\frac{|V_3W_4|}{|W_3V_5|}\frac{|V_4W_5|}{|W_4V_1|}\frac{|V_5W_1|}{|W_5V_2|} = 1.$$

In general, it is also true that

$$\frac{|V_iW_i|}{|W_{i+1}V_{i+2}|} = \frac{|V_iV_{i+1}V_{i+4}|}{|V_iV_{i+1}V_{i+2}V_{i+4}|}\frac{|V_iV_{i+1}V_{i+2}V_{i+3}|}{|V_{i+2}V_{i+3}V_{i+1}|}.$$

This type of identity was generalized to other figures in the plane and their duals by Pinkernell (1996).

Hoffman's Minimal Surface

A MINIMAL EMBEDDED SURFACE discovered in 1992 consisting of a HELICOID with a HOLE and HANDLE (*Science News* 1992). It has the same topology as a PUNCTURED sphere with a handle, and is only the second complete embedded minimal surface of finite topology and infinite total curvature discovered (the HELICOID being the first).

A three-ended MINIMAL SURFACE of GENUS 1 is sometimes also called Hoffman's minimal surface (Peterson 1988).

See also HELICOID, MINIMAL SURFACE

Hoffman-Singleton Graph

The only REGULAR GRAPH of VERTEX DEGREE 7, DIAMETER 2, and GIRTH 5. It is the unique (7, 5)-MOORE GRAPH (and is therefore also a (7,5)-CAGE GRAPH), and contains many copies of the PETERSEN GRAPH. It can be constructed from the 10 5-cycles illustrated above, with vertex i of P_j joined to vertex $i+jk$ (mod 5) of Q_k (Robertson 1969; Bondy and Murty 1976, p. 239; Wong 1982). (Note the correction of Wong's $j+jk$ to $i+jk$.)

Other constructions are given by (Benson and Losey 1971; Biggs 1993, p. 163), and a RADIAL EMBEDDING is illustrated above.

Hoffman-Singleton Theorem

Let G be a k-regular graph with GIRTH 5 and GRAPH DIAMETER 2. (Such a graph is a MOORE GRAPH). Then, $k = 2, 3, 7$, or 57. A proof of this theorem is difficult (Hoffman and Singleton 1960, Feit and Higman 1964, Damerell 1973, Bannai and Ito 1973), but can be found in Biggs (1993).

Hofstadter Figure-Figure Sequence

Define $F(1)=1$ and $S(1)=2$ and write

$$F(n)=F(n-1)+S(n-1),$$

where the sequence $\{S(n)\}$ consists of those integers not already contained in $\{F(n)\}$. For example, $F(2)=F(1)+S(1)=3$, so the next term of $S(n)$ is $S(2)=4$, giving $F(3)=F(2)+S(2)=7$. The next integer is 5, so $S(3)=5$ and $F(4)=F(3)+S(3)=12$. Continuing in this manner gives the "figure" sequence $F(n)$ as 1, 3, 7, 12, 18, 26, 35, 45, 56, ... (Sloane's A005228) and the "space" sequence as 2, 4, 5, 6, 8, 9, 10, 11, 13, 14, ... (Sloane's A030124).

Hofstadter G-Sequence

The sequence defined by $G(0)=0$ and

$$G(n)=n-G(G(n-1)).$$

The first few terms are 1, 1, 2, 3, 3, 4, 4, 5, 6, 6, 7, 8, 8, 9, 9, ... (Sloane's A005206).

Hofstadter Male-Female Sequences

The pair of sequences defined by $F(0)=1$, $M(0)=0$, and

$$F(n)=n-M(F(n-1))$$

$$M(n)=n-F(M(n-1)).$$

The first few terms of the "male" sequence $M(n)$ are 0, 1, 2, 2, 3, 4, 4, 5, 6, 6, 7, 7, 8, 9, 9, ... (Sloane's A005379), and the first few terms of the "female" sequence $F(n)$ are 1, 2, 2, 3, 3, 4, 5, 5, 6, 6, 7, 8, 8, 9, 9, ... (Sloane's A005378).

Hofstadter Point

The r-HOFSTADTER TRIANGLE of a given TRIANGLE ΔABC is perspective to ΔABC, and the PERSPECTIVE CENTER is called the Hofstadter point. The TRIANGLE CENTER FUNCTION is

$$\alpha=\frac{\sin(rA)}{\sin(r-rA)}.$$

As $r\to 0$, the TRIANGLE CENTER FUNCTION approaches

$$\alpha=\frac{A}{a},$$

and as $r\to 1$, the TRIANGLE CENTER FUNCTION approaches

$$\alpha=\frac{a}{A}.$$

Hofstadter Sequences

Let $b_1=1$ and $b_2=2$ and for $n\geq 3$, let b_n be the least INTEGER $> b_{n-1}$ which can be expressed as the SUM of two or more consecutive terms. The resulting sequence is 1, 2, 3, 5, 6, 8, 10, 11, 14, 16, ... (Sloane's A005243). Let $c_1=2$ and $c_2=3$, form all possible expressions OF THE FORM c_ic_j-1 for $1\leq i<j\leq n$, and append them. The resulting sequence is 2, 3, 5, 9, 14, 17, 26, 27, ... (Sloane's A005244).

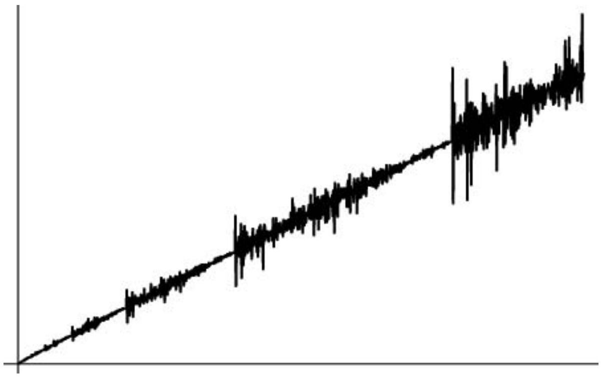
Hofstadter Triangle



For a NONZERO REAL NUMBER r and a TRIANGLE ΔABC, swing LINE SEGMENT BC about the vertex B towards vertex A through an ANGLE rB. Call the line along the rotated segment L. Construct a second line L' by rotating LINE SEGMENT BC about vertex C through an ANGLE rC. Now denote the point of intersection of L and L' by $A(r)$. Similarly, construct $B(r)$ and $C(r)$. The TRIANGLE having these points as vertices is called the Hofstadter r-triangle. Kimberling (1994) showed that the Hofstadter triangle is perspective to ΔABC, and calls PERSPECTIVE CENTER the HOFSTADTER POINT.

See also HOFSTADTER POINT

Hofstadter's Q-Sequence

The INTEGER SEQUENCE given by

$$Q(n) = Q(n - Q(n-1)) + Q(n - Q(n-2)),$$

with $Q(1) = Q(2) = 1$. The first few values are 1, 1, 2, 3, 3, 4, 5, 5, 6, 6, ... (Sloane's A005185; illustrated above). These numbers are sometimes called Q-NUMBER.

There are currently no rigorous analyses or detailed predictions of the rather erratic behavior of $Q(n)$ (Guy 1994). It has, however, been demonstrated that the chaotic behavior of the Q-numbers shows some signs of order, namely that they exhibit approximate PERIOD DOUBLING, SELF-SIMILARITY and SCALING (Pinn 1998). These properties are shared with the related sequence

$$D(n) = D(D(n-1)) + D(n - 1 - D(n-2))$$

with $D(1) = D(2) = 1$, which exhibits exact PERIOD DOUBLING (Pinn 1998). The chaotic regions of $D(n)$ are separated by predictable smooth behavior.

Hofstadter-Conway $10,000 Sequence

The INTEGER SEQUENCE defined by the RECURRENCE RELATION

$$a(n) = a(a(n-1)) + a(n - a(n-1))$$

with $a(1) = a(2) = 1$. The first few values are 1, 1, 2, 2, 3, 4, 4, 4, 5, 6, ... (Sloane's A004001). Plotting $a(n)/n$ against n gives the BATRACHION plotted below. Conway (1988) showed that $\lim_{n\to\infty} a(n)/n = 1/2$ and offered a prize of $10,000 to the discoverer of a value of n for which $|a(i)/i - 1/2| < 1/20$ for $i > n$. The prize was subsequently claimed by Mallows, after adjustment to Conway's "intended" prize of $1,000 (Schroeder 1991), who found $n = 1489$.

$a(n)/n$ takes a value of 1/2 for n OF THE FORM 2^k with $k = 1, 2, ...$ Pickover (1996) gives a table of analogous values of n corresponding to different values of $|a(n)/n - 1/2| < e$.

Hölder Condition

A function $\phi(t)$ satisfies the Hölder condition on two points t_1 and t_2 on an arc L when

$$|\phi(t_2)-\phi(t_1)| \leq A|t_2-t_1|^{\mu},$$

with A and μ POSITIVE REAL constants.

See also LIPSCHITZ CONDITION

Hölder Integral Inequality

If

$$C(r)$$

with $p, q > 1$, then

$$t_1$$

with equality when

$$t_2$$

If $|\phi(t_2)-\phi(t_1)| \leq A|t_2-t_1|^{\mu}$, this inequality becomes SCHWARZ'S INEQUALITY.

Hölder Sum Inequality

If

$$C(r)$$

with $p, q > 1$, then

$$\frac{1}{p}+\frac{1}{q}=1$$

with equality when $q>1$. If $|\phi(t_2)-\phi(t_1)| \leq A|t_2-t_1|^{\mu}$, this becomes CAUCHY'S INEQUALITY.

References

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, p. 11, 1972.

Hölder's Inequalities

Let

$$\frac{1}{p}+\frac{1}{q}=1 \tag{1}$$

with $p, q > 1$. Then Hölder's inequality for integrals states that

$$\int_a^b |f(x)g(x)|\,dx \leq \left[\int_a^b |f(x)|^p\,dx\right]^{1/p} \left[\int_a^b |g(x)|^q\,dx\right]^{1/q}, \tag{2}$$

with equality when

$$|g(x)|=c|f(x)|^{p-1}.$$

If $p=q=2$, this inequality becomes SCHWARZ'S INEQUALITY.

Similarly, Hölder's inequality for sums states that

$$\sum_{k=1}^{n} |a_k b_k| \leq \left(\sum_{k=1}^{n} |a_k|^p\right)^{1/p} \left(\sum_{k=1}^{n} |b_k|^q\right)^{1/q}, \tag{3}$$

with equality when $|b_k|=c|a_k|^{p-1}$. If $p=q=2$, this becomes CAUCHY'S INEQUALITY.

Holditch's Theorem

Let a CHORD of constant length be slid around a smooth, closed, convex curve C, and choose a point on the CHORD which divides it into segments of lengths p and q. This point will trace out a new closed curve C', as illustrated above. Provided certain conditions are met, the area between C and C' is given by πpq, as first shown by Holditch in 1858.

The Holditch curve for a CIRCLE of RADIUS R is another CIRCLE which, from the theorem, has RADIUS

$$r = \sqrt{R^2 - pq}.$$

Hole

A hole in a mathematical object is a TOPOLOGICAL structure which prevents the object from being continuously shrunk to a point. When dealing with TOPOLOGICAL SPACES, a DISCONNECTIVITY is interpreted as a hole in the space. Examples of holes are things like the "donut hole" in the center of the TORUS, a domain removed from a plane, and the portion missing from EUCLIDEAN SPACE after cutting a KNOT out from it.

Singular HOMOLOGY GROUPS form a MEASURE of the hole structure of a SPACE, but they are one particular measure and they don't always detect all holes. HOMOTOPY GROUPS of a SPACE are another measure of holes in a SPACE, as well as BORDISM GROUPS, K-THEORY, COHOMOTOPY GROUPS, and so on.

There are many ways to measure holes in a space. Some holes are picked up by HOMOTOPY GROUPS that are not detected by HOMOLOGY GROUPS, and some holes are detected by HOMOLOGY GROUPS that are not picked up by HOMOTOPY GROUPS. (For example, in the TORUS, HOMOTOPY GROUPS "miss" the two-dimensional hole that is given by the TORUS itself, but the second HOMOLOGY GROUP picks that hole up.) In addition, HOMOLOGY GROUPS don't detect the varying hole structures of the complement of KNOTS in 3-space, but the first HOMOTOPY GROUP (the fundamental group) does.

Holographic Projection

EQUAL-AREA PROJECTION

Holography

The mathematical study of a nonlinear equation $f(\varphi) = y$, where f maps from a HILBERT SPACE X to a HILBERT SPACE Y and $y \in Y$ which abstracts the construction of optical holograms.

References

Lannes, A. "Abstract Holography." *J. Math. Anal. Appl.* **74**, 530–59, 1980.

Holomorphic Function

A synonym for ANALYTIC FUNCTION, regular function, differentiable function, complex differentiable function, and holomorphic map (Krantz 1999, p. 16). The word derives from the Greek $o\lambda o\varsigma$ (*holos*), meaning "whole," and $\mu o\rho\varphi\eta$ (*morphe*), meaning "form" or "appearance."

Many mathematicians prefer the term "holomorphic function" (or "holomorphic map") to "analytic function" (Krantz 1999, p. 16), while "analytic" appears to be in widespread use among physicists, engineers, and in some older texts (Morse and Feshbach 1953, pp. 356–74; Knopp 1996, pp. 83–11; Whittaker and Watson 1990, p. 83).

Holomorphic Line Bundle

A COMPLEX LINE BUNDLE is a VECTOR BUNDLE $\pi : E \to M$ whose FIBERS $\pi^{-1}(m)$ are a copy of $\mathbb{C}$. π is a holomorphic line bundle if it is a HOLOMORPHIC MAP between COMPLEX MANIFOLDS and its TRANSITION FUNCTIONS are HOLOMORPHIC.

On a compact RIEMANN SURFACE, a DIVISOR $\Sigma n_i p_i$ determines a LINE BUNDLE. For example, consider $2p - q$ on X. Around p there is a COORDINATE CHART U given by the HOLOMORPHIC FUNCTION z_p with $z_p(p) = 0$. Similarly, z_q is a HOLOMORPHIC FUNCTION defining a disjoint chart V around q with $z_q(q) = 0$. Then letting $W = X - \{p, q\}$, the RIEMANN SURFACE is covered by $X = U \cup V \cup W$. The LINE BUNDLE corresponding to $2p - q$ is then defined by the following TRANSITION FUNCTIONS,

$$g_{UW}(x) = z_p(x)^2 \text{ defined for } x \in U \cap W$$

$$g_{VW}(x) = z_q(x)^{-1} \text{ defined for } x \in V \cap W.$$

Holomorphic Map

HOLOMORPHIC FUNCTION

Holomorphic Tangent Bundle

The holomorphic tangent bundle to a COMPLEX MANIFOLD is given by its complexified tangent vectors which are of type (1, 0). In a CHART $z = (z_1, \ldots, z_n)$, the bundle is spanned by the local SECTIONS $\partial/\partial z_k$. The antiholomorphic sections are spanned by $\partial/\partial \bar{z}_k$, of type (0, 1), where $\bar{z}$ denotes the COMPLEX CONJUGATE.

See also COMPLEX STRUCTURE, CR-STRUCTURE, HERMITIAN METRIC, HOLOMORPHIC LINE BUNDLE, HOLOMORPHIC VECTOR BUNDLE, TANGENT BUNDLE

Holomorphic Vector Bundle

A COMPLEX VECTOR BUNDLE is a VECTOR BUNDLE $\pi : E \to M$ whose FIBERS $\pi^{-1}(m)$ are a copy of $\mathbb{C}^k$. π is a holomorphic vector bundle if it is a HOLOMORPHIC MAP between COMPLEX MANIFOLDS and its TRANSITION FUNCTIONS are HOLOMORPHIC. The simplest example is a HOLOMORPHIC LINE BUNDLE, where the fiber is simply a copy of $\mathbb{C}$.

Holonomic Constant

A limiting value of a HOLONOMIC FUNCTION near a SINGULAR POINT. Holonomic constants include APÉRY'S CONSTANT, CATALAN'S CONSTANT, PÓLYA'S RANDOM WALK CONSTANTS for $d > 2$, and PI.

Holonomic Function

A solution of a linear homogeneous ORDINARY DIFFERENTIAL EQUATION with POLYNOMIAL COEFFICIENTS.

See also HOLOMORPHIC FUNCTION, HOLONOMIC CONSTANT

Holonomy

A general concept in CATEGORY THEORY involving the globalization of topological or differential structures. The term derives from the Greek $o\lambda o\varsigma$ (*holos*) "whole" and $\nu o\mu o\varsigma$ (*nomos*) "law, rule."

See also HOLONOMY GROUP, MONODROMY

Holonomy Group

On a RIEMANNIAN MANIFOLD M, tangent vectors can be moved along a path by PARALLEL TRANSPORT, which preserves VECTOR ADDITION and SCALAR MULTIPLICATION. So a closed loop at a base point p, gives rise to a INVERTIBLE LINEAR MAP of TM_p, the tangent vectors at p. It is possible to compose closed loops by following one after the other, and to invert them by going backwards. Hence, the set of linear transformations arising from PARALLEL TRANSPORT along closed loops is a GROUP, called the holonomy group.

Since PARALLEL TRANSPORT preserves the RIEMANNIAN METRIC, the holonomy group is contained in the ORTHOGONAL GROUP $O(n)$. Moreover, if the manifold is ORIENTABLE, then it is contained in the SPECIAL ORTHOGONAL GROUP. A generic RIEMANNIAN METRIC on an ORIENTABLE MANIFOLD has holonomy group $SO(n)$, but for some special metrics it can be a subgroup, in which case the manifold is said to have special holonomy.

A KÄHLER MANIFOLD is a $2n$-dimensional MANIFOLD whose holonomy lies in the UNITARY GROUP $U(n) \subset O(2n)$. A CALABI-YAU MANIFOLD is a SIMPLY CONNECTED $2n$-dimensional manifold with holonomy in the SPECIAL UNITARY GROUP. A 4_n-dimensional manifold with holonomy group $Sp(n)$, the QUATERNIONIC UNITARY GROUP, is called a HYPER-KÄHLER MANIFOLD, and one with holonomy $Sp(n)Sp(1)$ is called a QUATERNION KÄHLER MANIFOLD. The possible groups that can arise as a holonomy group of the metric compatible LEVI-CIVITA CONNECTION were classified by Berger. The other possibilities for a nonproduct, nonsymmetric MANIFOLD are the LIE GROUPS G_2, Spin(7), and Spin(9).

On a FLAT MANIFOLD, two homotopic loops give the same linear transformation. Consequently, the holonomy group is a REPRESENTATION of the FUNDAMENTAL GROUP of M. In general though, the CURVATURE of M changes the PARALLEL TRANSPORT between homotopic loops. In fact, there is a formula for the difference as an integral of the curvature.

Holyhedron

A polyhedron whose faces and holes are all finite-sided polygons and which contains at least one hole whose boundary shares no point with a face boundary. D. Wilson coined the term in 1997, although no actual holyhedron was known until 1999, when a holyhedron of GENUS approximately 54,000,000 was (apparently) constructed (Vinson 2000). J. H. Conway believes the construction to be correct, although he believes that the minimal GENUS should be closer to 100.

Homalographic Projection

EQUAL-AREA PROJECTION

Home Plate

Home plate in the game of BASEBALL is an irregular PENTAGON. However, the Little League rulebook's specification of the shape of home plate (Kreutzer and Kerley 1990), illustrated above, is not physically realizable, since it requires the existence of a (12, 12, 17) RIGHT TRIANGLE, whereas

$$12^2 + 12^2 = 288 \neq 289 = 17^2$$

(Bradley 1996).

Home Prime

The prime HP(n) reached starting from a number n, concatenating its prime factors, and repeating until a prime is reached. For example, for $n = 9$,

$$9 = 3 \cdot 3 \to 33 = 3 \cdot 11 \to 311,$$

so 311 is the home prime of 9. For $n = 2, 3, \ldots$, the first few are 2, 3, 211, 5, 23, 7, 3331113965338635107, 311, 773, ... (Sloane's A037274). Probabilistic arguments give exactly zero for the chance that the sequence of integers starting at a given number n contains no prime (J. H. Conway, Sloane), so a home prime should exist for every positive integer.

Since prime numbers have trivial home primes (themselves), we can restrict attention to composite numbers. The number of steps to arrive at a home prime for composite numbers 4, 6, 8, 9, ... are 1, 13, 2, 4, 1, 5, 4, 4, 1, 15, 1, ... (Sloane's A037271), and the primes they reach are 211, 23, 3331113965338635107, 311, 773, 223, ... (Sloane's A037272). The largest home prime for $n < 100$ is HP(49) = HP(77), although its value is not known. After 55 steps, the sequence reaches $3 \cdot 73 \cdot C105$, where $C105$ is the 105-digit composite number. This number was factored by P. Leyland in November 1999, and subsequently reached a number $C137$ in December 1999. In June 2000, Leyland factored this number as well, and proceeded a few steps to obtain a $C131$, which has not yet been factored. The next largest HP(n) for $n < 100$ is

$$\text{HP}(80) = 313,\ 169,\ 138,\ 727,\ 147,\ 145,\ 210,\ 044,$$
$$974,\ 146,\ 858,\ 220,\ 729,\ 781,\ 791,\ 489.$$

There are about 50 unknown HP(n) with $100 < n < 1000$ (Hoey).

Homeoid

A shell bounded by two similar ELLIPSOIDS having a constant ratio of axes. Given a CHORD passing through a homeoid, the distance between inner and outer intersections is equal on both sides. Since a spherical shell is a symmetric case of a homeoid, this theorem is also true for spherical shells (CONCENTRIC CIRCLES in the PLANE), for which it is easily proved by symmetry arguments.

See also CHORD, ELLIPSOID

Homeomorphic

There are two possible definitions:

1. Possessing similarity of form,
2. Continuous, ONE-TO-ONE, ONTO, and having a continuous inverse.

The most common meaning is possessing intrinsic topological equivalence. Two objects are homeomorphic if they can be deformed into each other by a continuous, invertible mapping. Such a HOMEOMORPHISM ignores the space in which surfaces are embedded, so the deformation can be completed in a higher dimensional space than the surface was originally embedded. MIRROR IMAGES are homeomorphic, as are MÖBIUS STRIP with an EVEN number of half-twists, and MÖBIUS STRIP with an ODD number of half-twists.

In CATEGORY THEORY terms, homeomorphisms are ISOMORPHISMS in the CATEGORY of TOPOLOGICAL SPACES and CONTINUOUS MAPS.

Homeomorphically Irreducible Tree

SERIES-REDUCED TREE

Homeomorphism

An EQUIVALENCE RELATION and one-to-one correspondence between points in two geometric figures or topological spaces which is continuous in both directions, also called a continuous transformation. A homeomorphism which also preserves distances is called an ISOMETRY. AFFINE TRANSFORMATIONS are another type of common geometric homeomorphism.

The similarity in meaning and form of the words "HOMOMORPHISM" and "homeomorphism" is unfortunate and a common source of confusion.

HOMFLY Polynomial

A 2-variable oriented KNOT POLYNOMIAL $P_L(a, z)$ motivated by the JONES POLYNOMIAL (Freyd *et al.* 1985). Its name is an acronym for the last names of its co-discoverers: Hoste, Ocneanu, Millett, Freyd, Lickorish, and Yetter (Freyd *et al.* 1985). Independent work related to the HOMFLY polynomial was also carried out by Prztycki and Traczyk (1987). HOMFLY polynomial is defined by the SKEIN RELATIONSHIP

$$a^{-1}P_{L+}(a, z) - aP_{L-}(a, z) = zP_{L_0}(a, z) \tag{1}$$

(Doll and Hoste 1991), where v is sometimes written instead of a (Kanenobu and Sumi 1993) or, with a slightly different relationship, as

$$\alpha P_{L+}(\alpha, z) - \alpha^{-1}P_{L_-}(\alpha, z) = zP_{L_0}(\alpha, z) \tag{2}$$

(Kauffman 1991). It is also defined as $P_L(\ell, m)$ in terms of SKEIN RELATIONSHIP

$$\ell P_{L+} + \ell^{-1}P_{L-} + mP_{L_0} = 0 \tag{3}$$

(Lickorish and Millett 1988). It can be regarded as a nonhomogeneous POLYNOMIAL in two variables or a homogeneous POLYNOMIAL in three variables. In three variables the SKEIN RELATIONSHIP is written

$$xP_{L+}(x, y, z) + yP_{L-}(x, y, z) + zP_{L_0}(x, y, z) = 0. \tag{4}$$

It is normalized so that $P_{\text{unknot}} = 1$. Also, for n unlinked unknotted components,

$$P_L(x, y, z) = \left(-\frac{x+y}{z}\right)^{n-1}. \tag{5}$$

This POLYNOMIAL usually detects CHIRALITY but does not detect the distinct ENANTIOMERS of the KNOTS 09-42, 10-48, 10-71, 10-91, 10-04, and 10-25 (Jones 1987). The HOMFLY polynomial of an oriented KNOT is the same if the orientation is reversed. It is a generalization of the JONES POLYNOMIAL $V(t)$, satisfying

$$V(t) = P(a = t,\ z = t^{1/2} - t^{-1/2}) \tag{6}$$

$$V(t) = P(\ell = it^{-1},\ m = i(t^{-1/2} - t^{1/2})). \tag{7}$$

It is also a generalization of the ALEXANDER POLYNOMIAL $\nabla(z)$, satisfying

$$\nabla(z) = P(a = 1,\ z = t^{1/2} - t^{-1/2}). \tag{8}$$

The HOMFLY POLYNOMIAL of the MIRROR IMAGE K^* of a KNOT K is given by

$$P_{K^*}(\ell, m) = P_K(\ell^{-1}, m), \tag{9}$$

so P usually but not always detects CHIRALITY.

A split union of two links (i.e., bringing two links together without intertwining them) has HOMFLY polynomial

$$P(L_1 \cup L_2) = -(\ell + \ell^{-1})m^{-1}P(L_1)P(L_2). \tag{10}$$

Also, the composition of two links

$$P(L_1 \# L_2) = P(L_1)P(L_2), \tag{11}$$

so the POLYNOMIAL of a COMPOSITE KNOT factors into POLYNOMIALS of its constituent knots (Adams 1994).

MUTANTS have the same HOMFLY polynomials. In fact, there are infinitely many distinct KNOTS with the same HOMFLY POLYNOMIAL (Kanenobu 1986). Examples include (05-01, 10-32), (08-08, 10-29) (08-16, 10-56), and (10-25, 10-56) (Jones 1987). Incidentally, these also have the same JONES POLYNOMIAL.

M. B. Thistlethwaite has tabulated the HOMFLY polynomial for KNOTS up to 13 crossings.

See also ALEXANDER POLYNOMIAL, JONES POLYNOMIAL, KNOT POLYNOMIAL

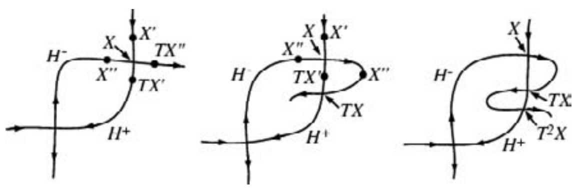
Homoclinic Point



A point where a stable and an unstable SEPARATRIX (invariant MANIFOLD) from the same fixed point or same family intersect. Therefore, the limits

$$\lim_{k \to \infty} f^k(X)$$

and

$$\lim_{k \to -\infty} f^k(X)$$

exist and are equal.

Refer to the above figure. Let X be the point of intersection, with X' ahead of X on one MANIFOLD and X'' ahead of X of the other. The mapping of each of these points TX' and TX'' must be ahead of the mapping of X, TX. The only way this can happen is if the MANIFOLD loops back and crosses itself at a new homoclinic point. Another loop must be formed, with T^2X another homoclinic point. Since T^2X is closer to the hyperbolic point than TX, the distance between T^2X and TX is less than that between X and TX. Area preservation requires the AREA to remain the same, so each new curve (which is closer than the previous one) must extend further. In effect, the loops become longer and thinner. The network of curves leading to a dense AREA of homoclinic points is known as a homoclinic tangle or tendril. Homoclinic points appear where CHAOTIC regions touch in a hyperbolic FIXED POINT.

A small DISK centered near a homoclinic point includes infinitely many periodic points of different periods. Poincaré showed that if there is a single homoclinic point, there are an infinite number. More specifically, there are infinitely many homoclinic points in each small disk (Nusse and Yorke 1996).

Homogeneous Barycentric Coordinates

AREAL COORDINATES

Homogeneous Cartesian Coordinates

HOMOGENEOUS COORDINATES

Homogeneous Coordinates

Homogeneous coordinates (x_1, x_2, x_3) of a finite point (x, y) in the plane are any three numbers for which

$$\frac{x_1}{x_3} = x \tag{1}$$

$$\frac{x_2}{x_3} = y. \tag{2}$$

Coordinates $(x_1, x_2, 0)$ for which

$$\frac{x_2}{x_3} = \lambda \tag{3}$$

describe the POINT AT INFINITY in the direction of slope λ.

In homogeneous coordinates, the equation of a LINE

$$a_1 x + a_2 y + a_3 = 0 \tag{4}$$

is given by

$$a_1 x_1 + a_2 x_2 + a_3 x_3 = 0. \tag{5}$$

Two points expressed using homogeneous coordinates (a_1, a_2, a_3) and (b_1, b_2, b_3) are identical IFF

$$\begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix} = \begin{vmatrix} a_3 & a_1 \\ b_3 & b_1 \end{vmatrix} = \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix} = 0. \tag{6}$$

Two lines expressed using homogeneous coordinates

$$a_1 x_1 + a_2 x_2 + a_3 x_3 = 0 \tag{7}$$

$$b_1 x_1 + b_2 x_2 + b_3 x_3 = 0 \tag{8}$$

are identical IFF

$$\begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix} = \begin{vmatrix} a_3 & a_1 \\ b_3 & b_1 \end{vmatrix} = \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix} = 0. \tag{9}$$

The intersection of the two lines above is given by

$$x_1 = \begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix} \tag{10}$$

$$x_2 = \begin{vmatrix} a_3 & a_1 \\ b_3 & b_1 \end{vmatrix} \tag{11}$$

$$x_3 = \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix}. \quad (12)$$

References

Graustein, W. C. "Homogeneous Cartesian Coordinates. Linear Dependence of Points and Lines." Ch. 3 in *Introduction to Higher Geometry*. New York: Macmillan, pp. 29–9, 1930.

Homogeneous Function

A function which satisfies

$$f(tx,\ ty) = t^n f(x,\ y)$$

for a fixed n. MEANS, the WEIERSTRASS ELLIPTIC FUNCTION, and TRIANGLE CENTER FUNCTIONS are homogeneous functions. A transformation of the variables of a TENSOR changes the TENSOR into another whose components are linear homogeneous functions of the components of the original TENSOR.

See also EULER'S HOMOGENEOUS FUNCTION THEOREM

Homogeneous Ideal

A homogeneous ideal I in a GRADED RING $R = \oplus A_i$ is an IDEAL generated by a set of homogeneous elements, i.e., each one is contained in only one of the A_i. For example, the POLYNOMIAL RING $\mathbb{C}[x] = \oplus A_i$ is a GRADED RING, where $A_i = \{ax^i\}$. The IDEAL $I = \langle x^2 \rangle$, i.e., all polynomials with no constant or linear terms, is a homogeneous ideal in $\mathbb{C}[x]$. Another homogeneous ideal is $I = \langle x^2 + y^2 + z^2,\ xy + yz + zx,\ z^5 \rangle$ in $\mathbb{C}[x,\ y,\ z]$.

Given any finite set of polynomials in n variables, the process of homogenization converts them to homogeneous polynomials in $n+1$ variables. If $f = f(x_1,\ \ldots,\ x_n)$ is a polynomial of degree d then

$$f^h(x_0,\ x_1,\ \ldots,\ x_n) = x_0^d f(x_1/x_0,\ \ldots,\ x_n/x_0)$$

is the homogenization of f. Similarly, if I is an IDEAL in $\mathbb{C}[x_1,\ \ldots,\ x_n]$, then $I^h = \{f^h | f \in I\}$ is its homogenization and is a homogeneous ideal. For example, if $f = x_1^3 + 2x_1x_2 - 3$ then $f^h = x_1^3 + 2x_0x_1x_2 - 3x_0^3$. Note that in general, if $I = \langle f_1,\ \ldots,\ f_k \rangle$ then I^h may have more elements than $\langle f_1^h,\ \ldots,\ f_k^h \rangle$. However, if $f_1, \ldots, f_k$ form a GRÖBNER BASIS using a graded monomial order, then $I^h = \langle f_1^h,\ \ldots,\ f_k^h \rangle$. A polynomial is easily dehomogenized by setting the extra variable $x_0 = 1$.

Here is a *Mathematica* function which takes a polynomial, in variables *vars*, and homogenizes it with the variable *x0*.

```
(*dg finds the degree of the polynomial f*)
    dg[f_?PolynomialQ,   {vars_?AtomQ}]   :=
Exponent[f, vars];
  dg[f_?PolynomialQ, vars_?ListQ] :=
  Max[MapIndexed[(dg[#1, Rest[vars]] + #2 - 1
&), CoefficientList[f, First[vars]]]];  (*uses
dg  =  degree of polynomial above*)
    Homogenize[f_?PolynomialQ,   vars_?ListQ,
x0_?AtomQ]  :=
  Expand[x0 ^ dg[f, vars] f /. Map[(#1 -> #1/
x0 &), vars]]
```

Here is a *Mathematica* function which dehomogenizes a polynomial in the variable *x0*.

```
Dehomogenize[f_?PolynomialQ, x0_?AtomQ]  :=  f
/. x0 -> 1
```

The AFFINE VARIETY V corresponding to a homogeneous ideal has the property that $x \in V$ IFF $cx \in V$ for all COMPLEX c. Therefore, a homogeneous ideal defines an ALGEBRAIC VARIETY in COMPLEX PROJECTIVE SPACE.

References

Hartshorne, R. *Algebraic Geometry*. New York: Springer-Verlag, 1977.

Homogeneous Numbers

Two numbers are homogeneous if they have identical PRIME FACTORS. An example of a homogeneous pair is (6, 72), both of which share PRIME FACTORS 2 and 3:

$$6 = 2 \cdot 3$$

$$72 = 2^3 \cdot 3^2.$$

See also HETEROGENEOUS NUMBERS, PRIME FACTORS, PRIME NUMBER

References

Le Lionnais, F. *Les nombres remarquables*. Paris: Hermann, p. 146, 1983.

Homogeneous Polynomial

A multivariate polynomial (i.e., a POLYNOMIAL in more than one variable) with all terms having the same degree. For example, $x^3 + xyz + y^2z + z^3$ is a homogeneous polynomial of degree three. SYMMETRIC POLYNOMIALS are always homogeneous.

See also FORM (POLYNOMIAL), POLYNOMIAL, SYMMETRIC POLYNOMIAL

Homogeneous Space

A homogeneous space M is a SPACE with a TRANSITIVE GROUP ACTION by a LIE GROUP. Because a TRANSITIVE GROUP ACTION implies that there is only one ORBIT, M is ISOMORPHIC to the QUOTIENT SPACE G/H where H

is the ISOTROPY GROUP G_x. The choice of $x \in M$ does not affect the isomorphism type of G/G_x because all of the ISOTROPY GROUPS are CONJUGATE.

Many common spaces are homogeneous spaces, such as the HYPERSPHERE,

$$S^n \sim O(n+1)/O(n), \tag{1}$$

and the COMPLEX PROJECTIVE SPACE

$$\mathbb{C}\P^n \sim U(n+1)/U(n) \times U(1). \tag{2}$$

The real GRASSMANNIAN of k-dimensional SUBSPACES in $\mathbb{R}^{n+k}$ is

$$O(n+k)/O(n) \times O(k). \tag{3}$$

The projection $\pi : G \to G/H$ makes G a PRINCIPAL BUNDLE on G/H with FIBER H. For example, $\pi : SO(3) \to SO(3)/SO(2) \sim \mathbb{S}^2$ is a $SO(2)$ BUNDLE, i.e., a CIRCLE BUNDLE, on the sphere. The SUBGROUP

$$SO(2) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos t & -\sin t \\ 0 & \sin t & \cos t \end{bmatrix} \tag{4}$$

acts on the right, and does not affect the first column so $\pi(v_1 v_2 v_3) = v_1 \in \mathbb{S}^2$ is WELL DEFINED.

MOLLWEIDE PROJECTION

Homology

Homology is a concept which is used in many branches of algebra and topology. The basic example is degree one integral homology for a domain in $\mathbb{R}^2$. In this case, a HOMOLOGY CLASS is represented by a finite sum or difference of closed loops. For example, consider the loops in the twice PUNCTURED plane $\mathbb{R}^2 - \{(0, 0), (1, 0)\}$, illustrated above.

The equality $\alpha + \beta = \gamma$ holds in homology because the difference is the BOUNDARY of a COMPACTLY SUPPORTED region. The homology of a space is an algebraic object which reflects the topology. The algebraic tools used are called HOMOLOGICAL ALGEBRA, and in that language, the homology is a DERIVED FUNCTOR, the homology of a LONG EXACT SEQUENCE.

See also BOUNDARY (HOMOLOGY), COHOMOLOGY, DERIVED FUNCTOR, HOMOLOGY CLASS, HOMOLOGY (GEOMETRY), HOMOLOGY GROUP, INTERSECTION (HOMOLOGY), POINCARE DUALITY

Homology (Chain)

For every p, the kernel of $\partial_P : C_P \to C_{P-1}$ is called the group of cycles,

$$Z_P = \{c \in C_P : \partial(c) = 0\}. \quad (1)$$

The letter Z is short for the German word for cycle, "Zyklus." The image $\partial(C_{P+1})$ is contained in the group of cycles because $\partial \circ \partial = 0$, and is called the group of boundaries,

$$B_P = \{c \in C_P : \text{there exists } b \in C_{P+1} \text{ such that } \partial(b) = c\}. \quad (2)$$

The quotients $H_P = Z_P / B_P$ are the HOMOLOGY GROUPS of the chain.

Given a SHORT EXACT SEQUENCE of CHAIN COMPLEXES

$$0 \to A_* \to B_* \to C_* \to 0, \quad (3)$$

there is a LONG EXACT SEQUENCE in homology.

$$\ldots \to H_P(A) \to H_P(B) \to H_P(C) \xrightarrow{\delta} H_{P-1}(A) \to \ldots . \quad (4)$$

In particular, a cycle a in A_P with $\partial a = 0$, is mapped to a cycle b in B_P. Similarly, a boundary $\partial a'$ in A_P gets mapped to a boundary $\partial b'$ in B_P. Consequently, the map between homologies $H_P(A) \to H_P(B)$ is well-defined. The only map which is not that obvious is δ, called the CONNECTING HOMOMORPHISM, which is well-defined by the SNAKE LEMMA.

Proofs of this nature are (with a modicum of humor) referred to as DIAGRAM CHASING.

Homology (Topology)

Historically, the term "homology" was first used in a topological sense by Poincaré. To him, it meant pretty much what is now called a COBORDISM, meaning that a homology was thought of as a relation between MANIFOLDS mapped into a MANIFOLD. Such MANIFOLDS form a homology when they form the boundary of a higher-dimensional MANIFOLD inside the MANIFOLD in question.

To simplify the definition of homology, Poincaré simplified the spaces he dealt with. He assumed that all the spaces he dealt with had a triangulation (i.e., they were "SIMPLICIAL COMPLEXES"). Then instead of talking about general "objects" in these spaces, he restricted himself to subcomplexes, i.e., objects in the space made up only on the simplices in the TRIANGULATION of the space. Eventually, Poincaré's version of homology was dispensed with and replaced by the more general SINGULAR HOMOLOGY. SINGULAR HOMOLOGY is the concept mathematicians mean when they say "homology."

In modern usage, however, the word homology is used to mean HOMOLOGY GROUP. For example, if someone says "X did Y by computing the homology of Z," they mean "X did Y by computing the HOMOLOGY GROUPS of Z." But sometimes homology is used more loosely in the context of a "homology in a SPACE," which corresponds to *singular* homology groups.

Singular homology groups of a SPACE measure the extent to which there are finite (compact) boundaryless GADGETS in that SPACE, such that these GADGETS are not the boundary of other finite (compact) GADGETS in that SPACE.

A generalized homology or cohomology theory must satisfy all of the EILENBERG-STEENROD AXIOMS with the exception of the DIMENSION AXIOM.

Homology Axis

PERSPECTIVE AXIS

Homology Center

PERSPECTIVE CENTER

Homology Class

A homology class in a singular homology theory is represented by a finite LINEAR COMBINATION of geo-

metric subobjects with zero boundary. Such a linear combination is considered to be HOMOLOGOUS to zero if it is the boundary of something having dimension one greater. For instance, two points that can be connected by a path comprise the boundary for that path, so any two points in a component are homologous and represent the same homology class.

See also COHOMOLOGY, COHOMOLOGY CLASS, HOMOLOGY, HOMOLOGY GROUP, INTERSECTION (HOMOLOGY)

Homology Group

The term "homology group" usually means a singular homology group, which is an ABELIAN GROUP which partially counts the number of HOLES in a TOPOLOGICAL SPACE. In particular, singular homology groups form a MEASURE of the HOLE structure of a SPACE, but they are one particular measure and they don't always pick up everything.

In addition, there are "generalized homology groups" which are *not* singular homology groups.

See also HOMOLOGY (TOPOLOGY)

References

Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, 1993.

Homomorphic

Related to one another by a HOMOMORPHISM.

Homomorphism

A term used in CATEGORY THEORY to mean a general MORPHISM. The term derives from the Greek $o\mu o$ (*omo*) "alike" and $\mu o\rho\varphi\omega\sigma\iota\varsigma$ (*morphosis*), "to form" or "to shape." The similarity in meaning and form of the words "homomorphism" and "HOMEOMORPHISM" is unfortunate and a common source of confusion.

If G and H are GROUPS, then a group homomorphism of G into H is a function $\phi : G \to H$ which preserves the group operation, i.e., for all $g_1, g_2 \in G$,

$$(g_1 g_2)\phi = (g_1)\phi(g_2)\phi$$

(Yale 1988, p. 18).

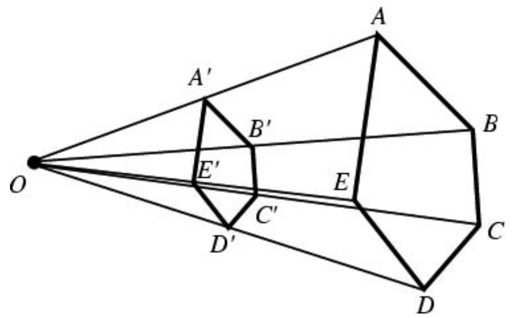
Homothetic



Two figures are homothetic if they are related by an EXPANSION or CONTRACTION. This means that they lie in the same plane and corresponding sides are PARALLEL; such figures have connectors of corresponding points which are CONCURRENT at a point known as the HOMOTHETIC CENTER. The HOMOTHETIC CENTER divides each connector in the same ratio k, known as the SIMILITUDE RATIO. For figures which are similar but do not have PARALLEL sides, a SIMILITUDE CENTER exists.

See also CONTRACTION (GEOMETRY), DIRECTLY SIMILAR, EXPANSION, HOMOTHECY, HOMOTHETIC CENTER, INVERSELY SIMILAR, PANTOGRAPH, PERSPECTIVE, SIMILAR, SIMILITUDE RATIO

Homothetic Center

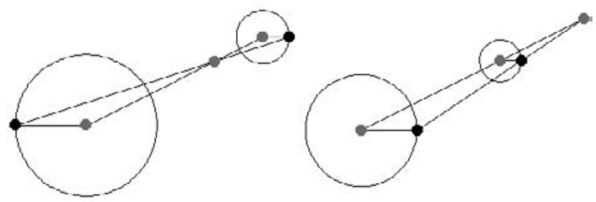
The meeting point of lines that connect corresponding points from HOMOTHETIC figures. In the above figure, O is the homothetic center of the HOMOTHETIC figures $ABCDE$ and $A'B'C'D'E'$. For figures which are similar but do not have PARALLEL sides, a SIMILITUDE CENTER exists (Johnson 1929, pp. 16–0).

Given two nonconcentric CIRCLES, draw RADII PARALLEL and in the same direction. Then the line joining the extremities of the RADII passes through a fixed point on the line of centers which divides that line externally in the ratio of RADII. This point is called the external homothetic center, or external center of similitude (Johnson 1929, pp. 19–0 and 41).

If RADII are drawn PARALLEL but instead in opposite directions, the extremities of the RADII pass through a fixed point on the line of centers which divides that line internally in the ratio of RADII (Johnson 1929, pp. 19–0 and 41). This point is called the internal homothetic center, or internal center of similitude (Johnson 1929, pp. 19–0 and 41).

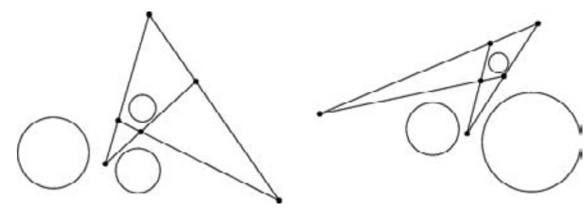
The position of the homothetic centers for two circles of radii r_i, centers (x_i, y_i), and segment angle θ are given by solving the simultaneous equations

$$y - y_2 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_2)$$



$$y - y_2^{\pm} = \frac{y_2^{\pm} - y_1^{\pm}}{x_2^{\pm} - x_1^{\pm}}(x - x_2^{\pm})$$

for (x, y), where



$$x_i^{\pm} \equiv x_i + (-1)^i r_i \cos\theta$$

$$y_i^{\pm} \equiv y_i + (-1)^i r_i \sin\theta,$$

and the plus signs give the external homothetic center, while the minus signs give the internal homothetic center.

As the above diagrams show, as the angles of the parallel segments are varied, the positions of the homothetic centers remain the same. This fact provides a (slotted) LINKAGE for converting circular motion with one radius to circular motion with another.

The six homothetic centers of three circles lie three by three on four lines (Johnson 1929, p. 120), which "enclose" the smallest circle.

The homothetic center of triangles is the PERSPECTIVE CENTER of HOMOTHETIC TRIANGLES. It is also called the SIMILITUDE CENTER (Johnson 1929, pp. 16–7).

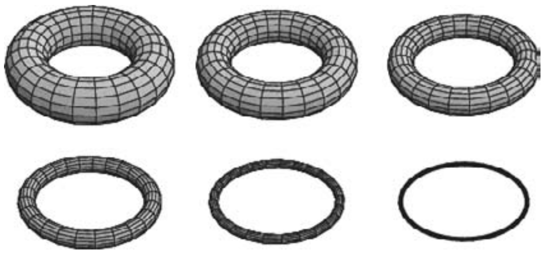
Homothetic Position

Two similar figures with PARALLEL homologous LINES and connectors of HOMOLOGOUS POINTS CONCURRENT at the HOMOTHETIC CENTER are said to be in homothetic position. If two SIMILAR figures are in the same plane but the corresponding sides are not PARALLEL, there exists a self-HOMOLOGOUS POINT which occupies the same homologous position with respect to the two figures.

Homothetic Triangles

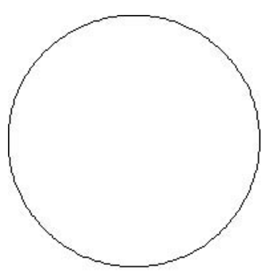


Nonconcurrent TRIANGLES with PARALLEL sides are always HOMOTHETIC. Homothetic triangles are al-

ways perspective triangles. Their perspective center is called their homothetic center.

Homothety

Homothecy



Homotopic

Two mathematical objects are said to be homotopic when they are the "same" in a certain abstract sense. For instance, the real line is homotopic to a single point, as is any tree. However, the circle is not contractible, but is homotopic to a solid torus. The basic version of homotopy is between maps. Two maps $f_0 : X \to Y$ and $f_1 : X \to Y$ are homotopic if there is a continuous map

$$F : X \times [0, 1] \to Y$$

such that $F(x, 0) = f_0(x)$ and $F(x, 1) = f_1(x)$.

Whether or not two subsets are homotopic depends on the ambient space. For example, in the plane, the unit circle is homotopic to a point, but not in the punctured plane $\mathbb{R}^2 - 0$. The puncture can be thought of as an obstacle.

However, there is a way to compare two spaces via homotopy without ambient spaces. Two spaces X and Y are homotopy equivalent if there are maps $f : X \to Y$ and $g : X \to Y$ such that the composition $f \circ g$ is homotopic to the identity map of Y and $g \circ f$ is homotopic to the identity map of X. For example, the circle is not homotopic to a point, for then the constant map would be homotopic to the identity map of a circle, which is impossible because they have different degrees.

See also Homeomorphism, Homotopy, Homotopy Class, Homotopy Group, Homotopy Type, Topological Space

Homotopy

A continuous transformation from one function to another. A homotopy between two functions f and g from a space X to a space Y is a continuous map G from $X \times [0, 1] \mapsto Y$ such that $G(x, 0) = f(x)$ and $G(x, 1) = g(x)$, where $\times$ denotes set pairing. Another way of saying this is that a homotopy is a path in the mapping space $\mathrm{Map}(X, Y)$ from the first function to the second.

See also h-Cobordism

References

Krantz, S. G. "The Concept of Homotopy" §10.3.2 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, pp. 132–33, 1999.

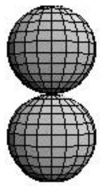
Homotopy Axiom

One of the Eilenberg-Steenrod axioms which states that, if $f : (X, A) \to (Y, B)$ is homotopic to $g : (X, A) \to (Y, B)$, then their induced maps $f_* : H_n(X, A) \to H_n(Y, B)$ and $g_* : H_n(X, A) \to H_n(Y, B)$ are the same.

Homotopy Class

Given two topological spaces M and N, place an equivalence relationship on the continuous maps $f : M \to N$ using homotopies, and write $f_1 \sim f_2$ if f_1 is homotopic to f_2. Roughly speaking, two maps are homotopic if one can be deformed into the other. This equivalence relation is transitive because these homotopy deformations can be composed (i.e., one can follow the other).

A simple example is the case of continuous maps from one circle to another circle. Consider the number of ways an infinitely stretchable string can be tied around a tree trunk. The string forms the first circle, and the tree trunk's surface forms the second circle. For any integer n, the string can be wrapped around the tree n times, for positive n clockwise, and negative n counterclockwise. Each integer n corresponds to a homotopy class of maps from $\mathbb{S}^1$ to $\mathbb{S}^1$.

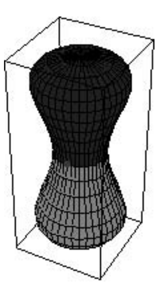


After the string is wrapped around the tree n times, it could be deformed a little bit to get another continuous map, but it would still be in the same homotopy class, since it is homotopic to the original map. Conversely, any map wrapped around n times can be deformed to any other.

See also Homotopy, Homotopy Group, Topological Space

Homotopy Group

The homotopy groups generalize the fundamental group to maps from higher dimensional spheres, instead of from the circle. The nth homotopy group of a topological space X is the set of homotopy classes of maps from the Hypersphere to X, with



a GROUP structure, and is denoted $\pi_n(X)$. The FUNDAMENTAL GROUP is $\pi_1(X)$, and, as in the case of π_1, the maps $\mathbb{S}^n \to X$ must pass through a BASEPOINT $p \in X$. For $n > 1$, the homotopy group $\pi_n(X)$ is an ABELIAN GROUP.

The group operations are not as simple as those for the FUNDAMENTAL GROUP. Consider two maps $a : \mathbb{S}^n \to X$ and $b : \mathbb{S}^n \to X$, which pass through $p \in X$. The product $a*b : \mathbb{S}^n \to X$ is given by mapping the equator to the BASEPOINT p. Then the northern hemisphere is mapped to the sphere by collapsing the equator to a point, and then it is mapped to X by a. The southern hemisphere is similarly mapped to X by b. The diagram above shows the product of two spheres.

The identity element is represented by the constant map $e(x) = p$. The choice of direction of a loop in the fundamental group corresponds to a ORIENTATION of $\mathbb{S}^n$ in a homotopy group. Hence the inverse of a map a is given by switching orientation for the sphere. By describing the sphere in $n+1$ coordinates, switching the first and second coordinate changes the orientation of the sphere. Or as a HYPERSURFACE, $\mathbb{S}^n \subset \mathbb{R}^{n+1}$, switching orientation reverses the roles of inside and outside. The above diagram shows that $a* -a$ is homotopic to the constant map, i.e., the identity. It begins by expanding the equator in $a* -a$, and then the resulting map is contracted to the BASEPOINT.

As with the FUNDAMENTAL GROUP, the homotopy groups do not depend on the choice of BASEPOINT. But the higher homotopy groups are always ABELIAN. The above diagram shows an example of $a*b = b*a$. The BASEPOINT is fixed, and because $n > 1$ the map can be rotated. When $n = 1$, i.e., the FUNDAMENTAL GROUP, it is impossible to rotate the map while keeping the BASEPOINT fixed.

A space with $\pi_i = 0$ for all $i \leq n$ is called n-connected. If X is $n-1$-connected, $n > 1$, then the HUREWICZ HOMOMORPHISM $\pi_n(X) \to H_n(X)$ from the nth-homotopy group to the nth-homology group is an ISOMORPHISM.

When $f : X \to Y$ is a CONTINUOUS MAP, then $f_* : \pi_n(X) \to \pi_n(Y)$ is defined by taking the images under f of the spheres in X. The pushforward is natural, i.e., $(f \circ g)_* = f_* \circ g_*$ whenever the composition of two maps is defined. In fact, given a FIBRATION,

$$F \to E \to B$$

where B is PATH-CONNECTED, there is a LONG EXACT SEQUENCE of homotopy groups

$$\ldots \to \pi_n(F) \to \pi_n(E) \to \pi_n(B) \to \pi_{n-1}(F) \to \ldots \to \pi_0(B) = 0.$$

Honaker's Constant

PALINDROMIC PRIME

Honeycomb

A TESSELLATION in n-D, for $n \geq 3$. The only regular honeycomb in 3-D is $\{4, 3, 4\}$, which consists of eight cubes meeting at each VERTEX. The only quasiregular honeycomb (with regular cells and semiregular VERTEX FIGURES) has each VERTEX surrounded by eight

TETRAHEDRA and six OCTAHEDRA and is denoted $\left\{\begin{matrix}3\\3,\ 4\end{matrix}\right\}$.

Ball and Coxeter (1987) use the term "sponge" for a solid which can be parameterized by INTEGERS p, q, and n which satisfy the equation

$$2\sin\left(\frac{\pi}{p}\right)\sin\left(\frac{\pi}{q}\right)=\cos\left(\frac{\pi}{n}\right).$$

The possible sponges are $\{p,\ q|n\}=\{6,\ 6|3\}$, $\{6,\ 4|4\}$, $\{4,\ 6|4\}$, $\{3,\ 6|6\}$, and $\{4,\ 4|\infty\}$.

There are many semiregular honeycombs, such as $\left\{\begin{matrix}3,\ 3\\4\end{matrix}\right\}$, in which each VERTEX consists of two OCTAHEDRA $\{3,\ 4\}$ and four CUBOCTAHEDRA $\left\{\begin{matrix}3\\4\end{matrix}\right\}$.

$$V(t) = -t - t^{-1}$$

and HOMFLY POLYNOMIAL

$$P(z,\ \alpha) = z^{-1}(\alpha^{-1} - \alpha^{-3}) + z\alpha^{-1}.$$

It has BRAID WORD σ_1^2.

Hopf Map

The first example discovered of a MAP from a higher-dimensional SPHERE to a lower-dimensional SPHERE which is not null-HOMOTOPIC. Its discovery was a shock to the mathematical community, since it was believed at the time that all such maps were null-HOMOTOPIC, by analogy with HOMOLOGY GROUPS.

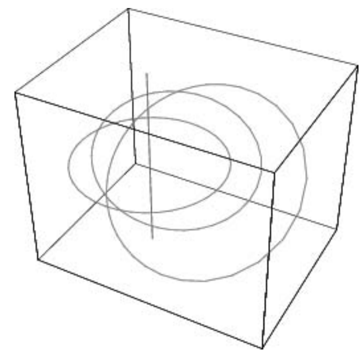
The Hopf map $f : \mathbb{S}^3 \to \mathbb{S}^2$ arises in many contexts, and can be generalized to a map $\mathbb{S}^7 \to \mathbb{S}^4$. For any point p in the sphere, its PREIMAGE $f^{-1}(p)$ is a circle $\mathbb{S}^1$ in $\mathbb{S}^3$. There are several descriptions of the Hopf map, also called the Hopf fibration.

As a SUBMANIFOLD of $\mathbb{R}^4$, the 3-SPHERE is

$$\mathbb{S}^3 = \{(X_1,\ X_2,\ X_3,\ X_4) : X_1^2 + X_2^2 + X_3^2 + X_4^2 = 1\} \quad (1)$$

and the 2-SPHERE is a SUBMANIFOLD of $\mathbb{R}^3$,

$$\mathbb{S}^2 = \{(x_1,\ x_2,\ x_3) : x_1^2 + x_2^2 + x_3^2 = 1\}. \quad (2)$$



The Hopf map takes points $(X_1,\ X_2,\ X_3,\ X_4)$ on a 3-sphere to points on a 2-sphere $(x_1,\ x_2,\ x_3)$

$$x_1 = 2(X_1X_2 + X_3X_4) \quad (3)$$

$$x_2 = 2(X_1X_4 - X_2X_3) \quad (4)$$

$$x_3 = (X_1^2 + X_3^2) - (X_2^2 + X_4^2). \quad (5)$$

Every point on the 2-SPHERE corresponds to a CIRCLE called the HOPF CIRCLE on the 3-SPHERE.

By STEREOGRAPHIC PROJECTION, the 3-sphere can be mapped to $\mathbb{R}^3$, where the point at infinity corresponds to the north pole. As a map, from $\mathbb{R}^3$, the Hopf map can be pretty complicated. The diagram above shows some of the preimages $f^{-1}(p)$, called HOPF CIRCLES. The straight red line is the circle through infinity.

By associating $\mathbb{R}^4$ with $\mathbb{C}^2$, the map is given by $f(z,\ w) = z/w$, which gives the map to the RIEMANN SPHERE.

The Hopf fibration is a FIBRATION

$$\mathbb{S}^1 \to \mathbb{S}^3 \to \mathbb{S}^2, \quad (6)$$

and is in fact a PRINCIPAL BUNDLE. The ASSOCIATED VECTOR BUNDLE

$$L = \mathbb{S}^3 \times \mathbb{C}/U(1), \quad (7)$$

where

$$((z,\ w),\ v) \sim ((e^{it}z,\ e^{it}w),\ e^{it}v) \quad (8)$$

is a complex LINE BUNDLE on $\mathbb{S}^2$. In fact, the set of line bundles on the sphere forms a group under TENSOR PRODUCT, and the bundle L generates all of them. That is, every line bundle on the sphere is $L^{\otimes k}$ for some k.

The sphere $\mathbb{S}^3$ is the LIE GROUP of unit QUATERNIONS, and can be identified with the SPECIAL UNITARY GROUP $SU(2)$, which is the SIMPLY CONNECTED double cover of $SO(3)$. The Hopf bundle is the quotient map $\mathbb{S}^2 \cong SU(2)/U(1)$.

Hopf Trace Theorem

Let K be a finite complex, and let $\phi : C_P(K) \to C_P(K)$ be a chain map, then

$$\sum_P (-1)^P \operatorname{Tr}(\phi,\ C_P(K)) = \sum_P (-1)^P \operatorname{Tr}(\phi_*,\ H_P(K)/T_P(K)).$$

Hopf's Theorem

A NECESSARY and SUFFICIENT condition for a MEASURE which is quasi-invariant under a transformation to be equivalent to an invariant PROBABILITY MEASURE is that the transformation cannot (in a measure theoretic sense) compress the SPACE.

Horn Function

The 34 distinct convergent hypergeometric series of order two enumerated by Horn (1931) and corrected by Borngässer (1933). There are 14 complete series for which $p = p' = q = q' = 2$,

$$F_1(\alpha,\ \beta,\ \beta',\ \gamma,\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_{m+n}(\beta)_m(\beta')_n}{(\gamma)_{m+n}m!n!}\ x^m y^n \tag{1}$$

$$F_2(\alpha,\ \beta,\ \beta',\ \gamma,\ \gamma',\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_{m+n}(\beta)_m(\beta')_n}{(\gamma)_m(\gamma')_n m!n!}\ x^m y^n \tag{2}$$

$$F_3(\alpha,\ \alpha',\ \beta,\ \beta',\ \gamma,\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_m(\alpha')_n(\beta)_m(\beta')_n}{(\gamma)_{m+n}m!n!}\ x^m y^n \tag{3}$$

$$F_4(\alpha,\ \beta,\ \gamma,\ \gamma',\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_{m+n}(\beta)_{m+n}}{(\gamma)_m(\gamma')_n m!n!}\ x^m y^n \tag{4}$$

$$G_1(\alpha,\ \beta,\ \beta',\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_{m+n}(\beta)_{n-m}(\beta')_{m-n}}{m!n!}\ x^m y^n \tag{5}$$

$$G_2(\alpha,\ \alpha',\ \beta,\ \beta',\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_m(\alpha')_n(\beta)_{n-m}(\beta')_{m-n}}{m!n!}\ x^m y^n \tag{6}$$

$$G_3(\alpha,\ \alpha',\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_{2n-m}(\alpha')_{2m-n}}{m!n!}\ x^m y^n \tag{7}$$

$$H_1(\alpha,\ \beta,\ \gamma,\ \delta,\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_{m-n}(\beta)_{m+n}(\gamma)_n}{(\delta)_m m!n!}\ x^m y^n \tag{8}$$

$$H_2(\alpha,\ \beta,\ \gamma,\ \delta,\ \epsilon,\ x,\ y) = \sum_{m,\ n} \frac{(\alpha)_{m-n}(\beta)_m(\gamma)_n(\delta)_n}{(\epsilon)_m m!n!}\ x^m y^n \tag{9}$$

$$H_3(\alpha,\ \beta,\ \gamma,\ x,\ y)=\sum_{m,\ n}\frac{(\alpha)_{2m+n}(\beta)_n}{(\gamma)_{m+n}m!n!}x^m y^n \tag{10}$$

$$H_4(\alpha,\ \beta,\ \gamma,\ \delta,\ x,\ y)=\sum_{m,\ n}\frac{(\alpha)_{2m+n}(\beta)_n}{(\gamma)_m(\delta)_n m!n!}x^m y^n \tag{11}$$

$$H_5(\alpha,\ \beta,\ \gamma,\ x,\ y)=\sum_{m,\ n}\frac{(\alpha)_{2m+n}(\beta)_{n-m}}{(\gamma)_n m!n!}x^m y^n \tag{12}$$

$$H_6(\alpha,\ \beta,\ \gamma,\ x,\ y)=\sum_{m,\ n}\frac{(\alpha)_{2m-n}(\beta)_{n-m}(\gamma)_n}{m!n!}x^m y^n \tag{13}$$

$$H_7(\alpha,\ \beta,\ \gamma,\ \delta,\ x,\ y)=\sum_{m,\ n}\frac{(\alpha)_{2m-n}(\beta)_n(\gamma)_n}{(\gamma)_m m!n!}x^m y^n \tag{14}$$

(of which F_1, F_2, F_3, and F_4 are precisely Appell hypergeometric functions), and 20 confluent series with $p \le p'=2$, $q \le q'=2$, and $p,\ q$ not both 2,

$$\Phi_1(\alpha,\ \beta,\ \gamma,\ x,\ y)=\sum_{m,\ n}\frac{(\alpha)_{m+n}(\beta)_n}{(\gamma)_{m+n}m!n!}x^m y^n \tag{15}$$

$$\Phi_2(\beta,\ \beta',\ \gamma,\ x,\ y)=\sum_{m,\ n}\frac{(\beta)_m(\beta')_m}{(\gamma)_{m+n}m!n!}x^m y^n \tag{16}$$

Horn's Theorem

This entry contributed by FRED MANBY

Let

$$X = \{x_1 \geq x_2 \geq \cdots \geq x_n | x_i \in \mathbb{R}\} \tag{1}$$

and

$$Y = \{y_1 \geq y_2 \geq \cdots \geq y_n | y_i \in \mathbb{R}\}. \tag{2}$$

Then there exists an $n \times n$ HERMITIAN MATRIX with eigenvalues X and diagonal elements Y IFF

$$\sum_{i=1}^{t} (x_i - y_i) \geq 0 \quad \forall 1 \leq t \leq n \tag{3}$$

and with equality for $t = n$. The theorem is sometimes also known as Schur's theorem.

Horned Sphere

ALEXANDER'S HORNED SPHERE, ANTOINE'S HORNED SPHERE

Horner's Method

A method for finding roots of a polynomial equation $f(x) = 0$. Now find an equation whose roots are the roots of this equation diminished by r, so

$$\begin{aligned} 0 &= f(x + r) \\ &= f(r) + xf'(r) + \tfrac{1}{2}x^2 f''(r) + \tfrac{1}{3}x^3 f'''(r) + \ldots . \end{aligned} \tag{1}$$

The expressions for $f(r)$, $f'(r)$, ... are then found as in the following example, where

$$f(x) \equiv Ax^5 + Bx^4 + Cx^3 + Dx^2 + Ex + F. \tag{2}$$

Write the coefficients A, B, ..., F in a horizontal row, and let a new letter shown as a denominator stand for the sum immediately above it so, in the following example, $P = Ar + B$. The result is the following table.

A	B	C	D	E	F
	$\frac{Ar}{P}$	$\frac{Pr}{Q}$	$\frac{Qr}{R}$	$\frac{Rr}{S}$	$\frac{Sr}{\omega}$
	$\frac{Ar}{T}$	$\frac{Tr}{U}$	$\frac{Ur}{R}$	$\frac{Vr}{\chi}$	
	$\frac{Ar}{W}$	$\frac{Wr}{X}$	$\frac{Xr}{\psi}$		
	$\frac{Ar}{Y}$	$\frac{Yr}{\phi}$			
	$\frac{Ar}{\theta}$				

Solving for the quantities θ, ϕ, ψ, χ, and ω gives

$$\theta = 5Ar + B = \frac{1}{4!} f^{(iv)}(r) \tag{3}$$

$$\phi = 10Ar^2 + 4Br + C = \frac{1}{3!} f'''(r) \tag{4}$$

$$\psi = 10Ar^3 + 6Br^2 + 3Cr + D = \frac{1}{2!} f''(r) \tag{5}$$

$$\chi = 5Ar^4 + 4Br^3 + 3Cr^2 + 2Dr + E = f'(r) \tag{6}$$

$$\omega = Ar^5 + Br^4 + Cr^3 + Dr^2 + Er + F = f(r), \tag{7}$$

so the equation whose roots are the roots of $f(x) = 0$, each diminished by r, is

$$0 = Ax^5 + \theta x^4 + \phi x^3 + \psi x^2 + \chi x + \omega \tag{8}$$

(Whittaker and Robinson 1967).

To apply the procedure, first determine the integer part of the root through whatever means are needed, then reduce the equation by this amount. This gives the second digit, by which the equation is once again reduced (after suitable multiplication by 10) to find the third digit, and so on.

1	−4	0	5(1	−10	−500	2000(3
	1	−3	−3	3	−21	−1563
	−3	−3	2	−7	−521	437
	1	−2		3	−12	
	−2	−5		−4	−523	
	1			3		
	−1			−1		

To see the method applied, consider the problem of finding the smallest positive root of

$$x^3 - 4x^2 + 5 = 0. \tag{9}$$

This root lies between 1 and 2, so diminish the equation by 1, resulting in the left table shown above. The resulting diminished equation is

$$x^3 - x^2 - 5x + 2 = 0, \tag{10}$$

and roots which are ten times the roots of this equation satisfy the equation

$$x^3 - 10x^2 - 500x + 2000 = 0. \tag{11}$$

The root of this equation between 1 and 10 lies between 3 and 4, so reducing the equation by 3 produces the right table shown above, giving the transformed equation

$$x^3 - x^2 - 533 + 437 = 0. \tag{12}$$

This procedure can be continued to yield the root as approximately 1.3819659.

Horner's process really boils down to the construction of a DIVIDED DIFFERENCE table (Whittaker and Robinson 1967).

See also DIVIDED DIFFERENCE, NEWTON'S METHOD

Horner's Rule

A rule for POLYNOMIAL computation which both reduces the number of necessary multiplications and results in less numerical instability due to potential subtraction of one large number from another. The rule simply factors out POWERS of x, giving

$$a_n x^n + a_{n-1}x^{n-1} + \ldots + a_0 = ((a_n x + a_{n-1})x + \ldots)x + a_0.$$

Horner's rule can be implemented to form a POLYNOMIAL from a list of coefficients in *Mathematica* as follows.

```
PolynomialFromCoefs[l_List, x_] := Fold[x#1 +
#2 &, 0, l]
```

Hotelling T2 Distribution

A univariate distribution proportional to the F-DISTRIBUTION. If the vector **d** is Gaussian multivariate-distributed with zero mean and unit covariance matrix

$$\sum_{m,n} \frac{(\alpha)_{2m-n}(\beta)_n}{(\delta)_m m! n!} x^m y^n$$

and $H_{11}(\alpha, \beta, \gamma, \delta, x, y)$ is an

$$\sum_{m,n} \frac{(\alpha)_{m-n}(\beta)_n(\gamma)_n}{(\delta)_m m! n!} x^m y^n$$

matrix with a WISHART DISTRIBUTION with unit scale matrix and m degrees of freedom $X=\{x_1>x_2\geq\cdots\geq x_n|x_i\in\mathbb{R}\}$, then $Y=\{y_1\geq y_2\geq\cdots\geq y_n|y_i\in\mathbb{R}\}$ has the Hotelling $\Sigma_{i-1}^t(x_i-y_i)\geq 0 \quad \forall 1\leq t\leq n$ distribution with parameters p and m, denoted $t=n$. This distribution is commonly used to describe the sample Mahalanobis distance between two populations, and is implemented as `HotellingTSquareDistribution`[p, m] in the *Mathematica* add-on package `Statistics`MultinomialDistribution`` (which can be loaded with the command `<<Statistics``), where p is the dimensionality parameter and m is the number of degrees of freedom.

Howe's Theorem

Let P be a PRIMITIVE POLYTOPE with eight vertices. Then there is a unimodular map that maps P to the polyhedron whose vertices are (0, 0, 0), (1, 0, 0), (0, 1, 0), (0, 0, 1), (0, 1, 1), (1, a, b), (1, c, d), and (1, $a+c$, $b+d$) with $a,\ b,\ c,\ d \in \mathbb{Z}, a,\ b,\ c,\ d \geq 0$, and $ad-bc=1$. Furthermore, any primitive polyhedron with fewer than eight vertices can be embedded in one with eight vertices.

Howell Design

Let S be a set of $n+1$ symbols, then a Howell design $H(s,\ 2n)$ on symbol set S is an $s \times s$ array H such that

1. Every cell of H is either empty or contains an unordered pair of symbols from S,
2. Every symbol of S occurs once in each row and column of H, and
3. Every unordered pair of symbols occurs in at most one cell of H.

h-Statistic

An unbiased estimator for a MOMENT of a distribution.

See also κ-STATISTIC

H-Transform

A 2-D generalization of the HAAR TRANSFORM which is used for the compression of astronomical images. The algorithm consists of dividing the $2^N \times 2^N$ image into blocks of 2×2 pixels, calling the pixels in the block a_{00}, a_{10}, a_{01}, and a_{11}. For each block, compute the four coefficients

$$h_0 \equiv \tfrac{1}{2}(a_{11}+a_{10}+a_{01}+a_{00})$$

$$h_x \equiv \tfrac{1}{2}(a_{11}+a_{10}-a_{01}-a_{00})$$

$$h_y \equiv \tfrac{1}{2}(a_{11}-a_{10}+a_{01}-a_{00})$$

$$h_c \equiv \tfrac{1}{2}(a_{11}-a_{10}-a_{01}+a_{00}).$$

Construct a $2^{N-1} \times 2^{N-1}$ image from the h_0 values, and repeat until only one h_0 value remains. The H-transform can be performed in place and requires about $16N^2/3$ additions for an $N \times N$ image.

Huffman Coding

A lossless data compression algorithm which uses a small number of bits to encode common characters. Huffman coding approximates the probability for each character as a POWER of 1/2 to avoid complications associated with using a nonintegral number of bits to encode characters using their actual probabilities.

Huffman coding works on a list of weights $\{w_i\}$ by building an EXTENDED BINARY TREE with minimum weighted PATH LENGTH and proceeds by finding the two smallest w s, w_1 and w_2, viewed as external nodes, and replacing them with an internal node of weight w_1+w_2. The procedure is them repeated stepwise until the root node is reached. An individual external node can then encoded by a binary string of 0s (for left branches) and 1s (for right branches).

The procedure is summarized below for the weights 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, and 41 given by the first 13 primes, and the resulting tree is shown above (Knuth 1997, pp. 402–03). As is clear from the diagram, the paths to the larger weights are shorter than those to the smaller weights. In this example, the number 13 would be encoded as 1010.

Hull

AFFINE HULL, CONVEX HULL

Hull Number

Let a set of vertices A in a CONNECTED GRAPH G be called convex if for every two vertices $x,\ y \in A$, the vertex set of every $(x,\ y)$ GRAPH GEODESIC lies completely in A. Also define the convex hull $A \subseteq V(G)$ of a GRAPH G with vertex set $V(G)$ as the smallest CONVEX SET in G containing A. Then the smallest cardinality of a set A whose convex hull is $V(G)$ is called the hull number of G, denoted $h(G)$.

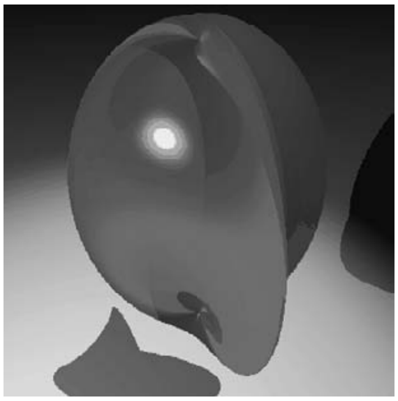
Hundkurve

TRACTRIX

Hundred

$100 = 10^2$. Madachy (1979) gives a number of algebraic equations using the digits 1 to 9 which evaluate to 100, such as

$$(7-5)^2 + 96 + 8 - 4 - 3 - 1 = 100$$
$$3^2 + 91 + 7 + 8 - 6 - 5 - 4 = 100$$
$$\sqrt{9} - 6 + 72 - (1)(3!) - 8 + 45 = 100$$
$$123 - 45 - 67 + 89 = 100,$$



and so on.

Huntington Axiom

An axiom proposed by Huntington (1933) as part of his definition of a BOOLEAN ALGEBRA,

$$H(x, y) \equiv !(!x \vee y) \vee !(!x \vee !y) = x, \tag{1}$$

where $!x$ denotes NOT and $x \vee y$ denotes OR. Taken together, the three axioms consisting of (1), commutativity

$$x \vee y = y \vee x \tag{2}$$

and associativity

$$(x \vee y) \vee z = x \vee (y \vee z), \tag{3}$$

are equivalent to the axioms of BOOLEAN ALGEBRA.

The Huntington operator can be defined in *Mathematica* by

```
Huntington := Function[{x, y}, ! (! x \[Or] y)
\[Or] ! (! x \[Or] ! y)]
```

That the Huntington axiom is a true statement in BOOLEAN ALGEBRA can be verified by examining its TRUTH TABLE.

x	y	$H(x, y)$
T	T	T
T	F	T
F	T	F
F	F	F

References

Guy, R. K. "Markoff Numbers." §D12 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 166–68, 1994.

Hurwitz Number

A number with a CONTINUED FRACTION whose terms are the values of one or more POLYNOMIALS evaluated on consecutive INTEGERS and then interleaved. This property is preserved by MÖBIUS TRANSFORMATIONS (Gosper 1972, p. 44).

References

Gosper, R. W. Item 101b in Beeler, M.; Gosper, R. W.; and Schroeppel, R. *HAKMEM.* Cambridge, MA: MIT Artificial Intelligence Laboratory, Memo AIM-239, pp. 39–4, Feb. 1972.

Hurwitz Polynomial

A POLYNOMIAL with REAL POSITIVE COEFFICIENTS and ROOTS which are either NEGATIVE or pairwise conjugate with NEGATIVE REAL PARTS.

Hurwitz Zeta Function

A generalization of the RIEMANN ZETA FUNCTION with a FORMULA

$$\zeta(s, a) \equiv \sum_{k=0}^{\infty} \frac{1}{(k+a)^s}, \tag{1}$$

where any term with $k + a = 0$ is excluded. The Hurwitz zeta function can also be given by the functional equation

$$\zeta\left(s, \frac{p}{q}\right) = 2\Gamma(1-s) \times (2\pi q)^{s-1} \sum_{n=1}^{q} \sin\left(\frac{\pi s}{2} + \frac{2\pi n p}{q}\right) \zeta\left(1-s, \frac{n}{q}\right) \tag{2}$$

(Apostol 1976, Miller and Adamchik), or the integral

$$\zeta(s, a) = \tfrac{1}{2} a^{-s} + \frac{a^{1-s}}{s-1} + 2\int_0^{\infty} (a^2 + y^2)^{-s/2} \left\{ \sin\left[s \tan^{-1}\left(\frac{y}{a}\right)\right]\right\} \frac{dy}{e^{2xy} - 1}. \tag{3}$$

If $\Re|z| < 0$ and $0 < a \le 1$, then

$$\zeta(z, a) = \frac{2\Gamma(1-z)}{(2\pi)^{1-z}} \times \left[\sin\left(\frac{\pi z}{2}\right) \sum_{n=1}^{\infty} \frac{\cos(2\pi a n)}{n^{1-z}} + \cos\left(\frac{\pi z}{2}\right) \sum_{n=1}^{\infty} \frac{\sin(2\pi a n)}{n^{1-z}} \right] \tag{4}$$

(Hurwitz 1882; Whittaker and Watson 1990, pp. 268–69). The Hurwitz zeta function satisfies

$$\zeta(0, a) = \tfrac{1}{2} - a \tag{5}$$

$$\frac{d}{ds} \zeta(0, a) = \ln[\Gamma(a)] - \tfrac{1}{2}\ln(2\pi) \tag{6}$$

$$\frac{d}{ds} \zeta(0, 0) = \tfrac{1}{2}\ln(2\pi), \tag{7}$$

where $\Gamma(z)$ is the GAMMA FUNCTION.

In the limit,

$$\lim_{s \to 1} \zeta(s, a) - \frac{1}{s-1} = \frac{\Gamma'(a)}{\Gamma(a)} \tag{8}$$

(Whittaker and Watson 1990, p. 271; Allouche 1992). The POLYGAMMA FUNCTION $\psi_m(z)$ can be expressed in terms of the Hurwitz zeta function by

$$\psi_m(z) = (-1)^{m+1} m! \zeta(1+m, z). \tag{9}$$

For POSITIVE INTEGERS k, p, and $q > p$,

$$\begin{aligned} \zeta'\left(-2k+1, \tfrac{p}{q}\right) &= \frac{[\psi(2k) - \ln(2\pi q)] B_{2k}(p/q)}{2k} - \frac{[\psi(2k) - \ln(2\pi)] B_{2k}}{q^{2k} 2k} \\ &+ \frac{(-1)^{k+1}\pi}{(2\pi q)^{2k}} \sum_{n=1}^{q-1} \sin\left(\frac{2\pi p n}{q}\right) \psi_{(2k-1)}\left(\frac{n}{q}\right) \\ &+ \frac{(-1)^{k+1} 2(2k-1)!}{(2\pi q)^{2k}} \sum_{n=1}^{q-1} \cos\left(\frac{2\pi p n}{q}\right) \zeta'\left(2k, \frac{n}{q}\right) \\ &+ \frac{\zeta'(-2k+1)}{q^2 k}, \end{aligned} \tag{10}$$

where B_n is a BERNOULLI NUMBER, $B_n(x)$ a BERNOULLI POLYNOMIAL, $\psi_n(z)$ is a POLYGAMMA FUNCTION, and $\zeta(z)$ is a RIEMANN ZETA FUNCTION (Miller and Adamchik). Miller and Adamchik also give the closed-form

expressions

$$\zeta'(-2k+1, \tfrac{1}{2}) = -\frac{B_{2k}\ln 2}{4^k k} - \frac{(2^{2k-1})\zeta'(-2k+1)}{2^{2k-1}} \quad (11)$$

$$\zeta'\left(-2k+1, \begin{matrix}1/3\\2/3\end{matrix}\right) = \mp\frac{(9^k-1)B_{2k}\pi}{\sqrt{3}(3^{2k-1}-1)8k} - \frac{B_{2k}\ln 3}{(3^{2k-1})4k} \quad (12)$$

$$\zeta'\left(-2k+1, \begin{matrix}1/4\\3/4\end{matrix}\right) = \mp\frac{(4^k+1)B_{2k}\pi}{4^{k+1}k} + \frac{(4^{k-1}-1)B_{2k}\ln 2}{2^{3k-1}k} \quad (13)$$

$$\zeta'\left(-2k+1, \begin{matrix}1/6\\5/6\end{matrix}\right) = \mp\frac{(9^k-1)(2^{2k-1}+1)B_{2k}\pi}{\sqrt{3}(6^{2k-1})8k} + \frac{B_{2k}(3^{2k-1}-1)\ln 2}{(6^{2k-1})4k} + \frac{B_{2k}(2^{2k-1}-1)\ln 3}{(6^{2k-1})4k} \mp \frac{(-1)^k(2^{2k-1}+1)\psi_{2k-1}(\frac{1}{3})}{2\sqrt{3}(12\pi)^{2k-1}} \quad (14)$$

In these equations, $\zeta'(z_0, a)$ means $d\zeta(z, a)/dz|_{z=z_0}$, $\zeta'(z_0)$ means $d\zeta(z)/dz|_{z=z_0}$, and the upper and lower fractions on the left side of the equations correspond to the plus and minus signs, respectively, on the right side.

Gauss gave

$$\frac{\Gamma'(p/q)}{\Gamma(p/q)} = -\gamma - \ln(2q) - \tfrac{1}{2}\pi\cot\left(\frac{\pi p}{q}\right) + 2\sum_{0<n<q/2}\cos\left(\frac{2\pi pn}{q}\right)\ln\left[\sin\left(\frac{\pi n}{q}\right)\right] \quad (15)$$

(Allouche 1992, Knuth 1997, p. 94).

Hurwitz's Irrational Number Theorem

As Lagrange showed, any IRRATIONAL NUMBER α has an infinity of rational approximations p/q which satisfy

$$\left|\alpha - \frac{p}{q}\right| < \frac{1}{\sqrt{5}q^2}. \quad (1)$$

Furthermore, if there are no integers a, b, c, d with $|ad-bc|=1$ and $\alpha = \frac{a\alpha+b}{d\alpha+c}$ (corresponding to values of α

associated with the GOLDEN RATIO ϕ through their CONTINUED FRACTIONS), then

$$\left|\alpha - \frac{p}{q}\right| < \frac{1}{\sqrt{8}q^2}, \qquad (2)$$

and if values of α associated with the SILVER RATIO $1+\sqrt{2}$ are also excluded, then

$$\left|\alpha - \frac{p}{q}\right| < \frac{5}{\sqrt{221}} \frac{1}{q^2}. \qquad (3)$$

In general, even tighter bounds OF THE FORM

$$\left|\alpha - \frac{p}{q}\right| < \frac{1}{L_n q^2} \qquad (4)$$

can be obtained for the best rational approximation possible for an arbitrary irrational number α, where the L_n are called LAGRANGE NUMBERS and get steadily larger for each "bad" set of irrational numbers which is excluded.

See also CONTINUED FRACTION, IRRATIONALITY MEASURE,

Hurwitz's Root Theorem

Let $\{f(x)\}$ be a SEQUENCE of ANALYTIC FUNCTIONS REGULAR in a region G, and let this sequence be UNIFORMLY CONVERGENT in every CLOSED SUBSET of G. If the ANALYTIC FUNCTION

$$\lim_{n\to\infty} f_n(x) = f(x)$$

does not vanish identically, then if $x = a$ is a zero of $f(x)$ of order k, a NEIGHBORHOOD $|x-a| < \delta$ of $x = a$ and a number N exist such that if $n > N$, $f_n(x)$ has exactly k zeros in $|x-a| < \delta$.

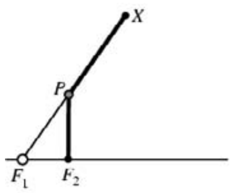
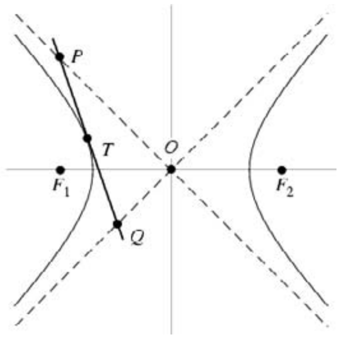
Hyperbola

A hyperbola is a CONIC SECTION defined as the LOCUS of all points P in the PLANE the difference of whose distances $r_1 = F_1P$ and $r_2 = F_2P$ from two fixed points (the FOCI F_1 and F_2) separated by a distance $2c$ is a given POSITIVE constant k,

$$r_2 - r_1 = k \qquad (1)$$

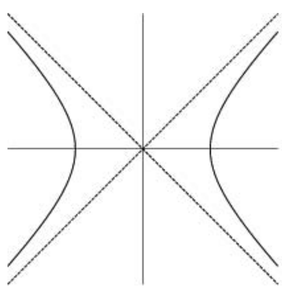


(Hilbert and Cohn-Vossen 1999, p. 3). Letting P fall on the left x-intercept requires that

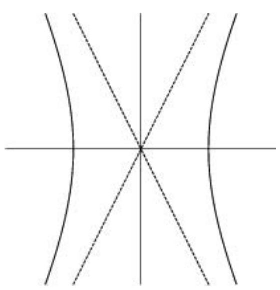


$$k = (c+a) - (c-a) = 2a, \qquad (2)$$

so the constant is given by $k = 2a$, i.e., twice the distance between the x-intercepts (left figure above). The hyperbola has the important property that a ray originating at a FOCUS F_1 reflects in such a way that the outgoing path lies along the line from the other FOCUS through the point of intersection (right figure above).



The special case of the RECTANGULAR HYPERBOLA, corresponding to a hyperbola with eccentricity $e = \sqrt{2}$, was first studied by Menaechmus. Euclid and Aristaeus wrote about the general hyperbola, but only studied one branch of it. The hyperbola was given its present name by Apollonius, who was the first to study both branches. The FOCUS and DIRECTRIX were considered by Pappus (MacTutor Archive). The hyperbola is the shape of an orbit of a body on an escape trajectory (i.e., a body with positive energy), such as



some comets, about a fixed mass, such as the sun.

The hyperbola can be constructed by connecting the free end X of a rigid bar F_1X, where F_1 is a FOCUS, and the other FOCUS F_2 with a string F_2PX. As the bar AX is rotated about F_1 and P is kept taut against the bar (i.e., lies on the bar), the LOCUS of P is one branch of a hyperbola (left figure above; Wells 1991). A theorem of Apollonius states that for a line segment tangent to the hyperbola at a point T and intersecting the asymptotes at points P and Q, then $\overline{OP} \times \overline{OQ}$ is constant, and $PT = QT$ (right figure above; Wells 1991).

Let the point P on the hyperbola have Cartesian coordinates (x, y), then the definition of the hyperbola $r_2 - r_1 = 2a$ gives

$$\sqrt{(x-c)^2 + y^2} - \sqrt{(x+c)^2 + y^2} = 2a. \quad (3)$$

Rearranging and completing the square gives

$$x^2(c^2 - a^2) - a^2y^2 = a^2(c^2 - a^2), \quad (4)$$

and dividing both sides by $a^2(c^2 - a^2)$ results in

$$\frac{x^2}{a^2} - \frac{y^2}{c^2 - a^2} = 1. \quad (5)$$

By analogy with the definition of the ELLIPSE, define

$$b^2 \equiv c^2 - a^2, \quad (6)$$

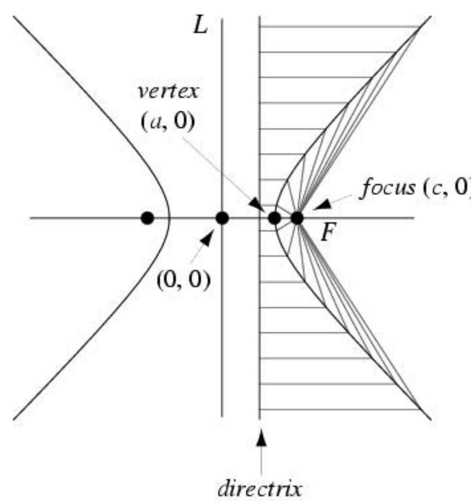
so the equation for a hyperbola with SEMIMAJOR AXIS a parallel to the X-AXIS and SEMIMINOR AXIS b parallel to the Y-AXIS is given by

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1. \quad (7)$$

or, for a center at the point (x_0, y_0) instead of $(0, 0)$,

$$\frac{(x - x_0)^2}{a^2} - \frac{(y - y_0)^2}{b^2} = 1. \quad (8)$$

Unlike the ELLIPSE, no points of the hyperbola actually lie on the SEMIMINOR AXIS, but rather the ratio b/a determines the vertical scaling of the hyperbola. The ECCENTRICITY e of the hyperbola (which always satisfies $e > 1$) is then defined as



$$e \equiv \frac{c}{a} = \sqrt{1 + \frac{b^2}{a^2}}. \quad (9)$$

In the standard equation of the hyperbola, the center is located at (x_0, y_0), the FOCI are at $(x_0 \pm c, y_0)$, and the vertices are at $(x_0 \pm a, y_0)$. The so-called ASYMPTOTES (shown as the dashed lines in the above figures) can be found by substituting 0 for the 1 on the right side of the general equation (8),

$$y = \pm \frac{b}{a}(x - x_0) + y_0, \quad (10)$$

and therefore have SLOPES $\pm b/a$.

The special case $a = b$ (the left diagram above) is known as a RIGHT HYPERBOLA because the ASYMPTOTES are PERPENDICULAR.

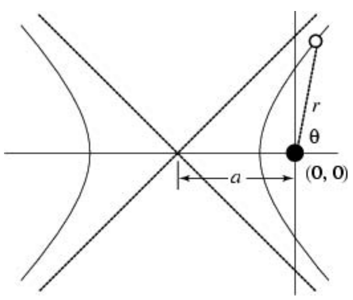
The hyperbola can also be defined as the LOCUS of points whose distance from the FOCUS F is proportional to the horizontal distance from a vertical line L known as the DIRECTRIX, where the ratio is > 1. Letting r be the ratio and d the distance from the center at which the directrix lies, then

$$d = \frac{a^2}{c} \quad (11)$$

$$r = \frac{a}{c}. \quad (12)$$

Like noncircular ELLIPSES, hyperbolas have *two* distinct FOCI and two associated DIRECTRICES, each DIRECTRIX being PERPENDICULAR to the line joining the two foci (Eves 1965, p. 275).

The FOCAL PARAMETER of the hyperbola is



$$p = \frac{b^2}{\sqrt{a^2 + b^2}} \quad (13)$$

$$= \frac{c^2 - a^2}{c} \quad (14)$$

$$= \frac{a(e^2 - 1)}{e}. \quad (15)$$

In POLAR COORDINATES, the equation of a hyperbola centered at the ORIGIN (i.e., with $x_0 = y_0 = 0$) is

$$r^2 = \frac{a^2 b^2}{b^2 \cos^2 \theta - a^2 \sin^2 \theta}. \quad (16)$$

In POLAR COORDINATES centered at a FOCUS,

$$r = \frac{a(e^2 - 1)}{1 - e \cos \theta}. \quad (17)$$

The two-center BIPOLAR COORDINATES equation with origin at a FOCUS is

$$r_1 - r_2 = \pm 2a. \quad (18)$$

The PARAMETRIC EQUATIONS for the hyperbola are

$$x = \pm a \cosh t \quad (19)$$

$$y = b \sinh t. \quad (20)$$

The CURVATURE and TANGENTIAL ANGLE are

$$\kappa(t) = -[\cosh(2t)]^{-3/2} \quad (21)$$

$$\phi(t) = -\tan^{-1}(\tanh t). \quad (22)$$

The LOCUS of the apex of a variable CONE containing an ELLIPSE fixed in 3-space is a hyperbola through the FOCI of the ELLIPSE. In addition, the LOCUS of the apex of a CONE containing that hyperbola is the original ELLIPSE. Furthermore, the ECCENTRICITIES of the ELLIPSE and hyperbola are reciprocals.

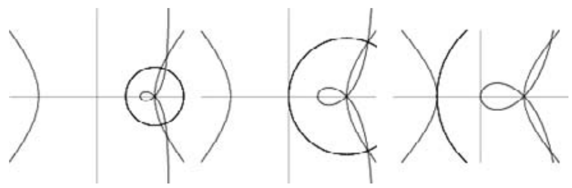
Hyperbola Evolute

The EVOLUTE of a RECTANGULAR HYPERBOLA is the LAMÉ CURVE

$$(ax)^{2/3} - (by)^{2/3} = (a + b)^{2/3}.$$

From a point between the two branches of the EVOLUTE, two NORMALS can be drawn to the HYPERBOLA. However, from a point beyond the EVOLUTE, four NORMALS can be drawn.

Hyperbola Inverse Curve



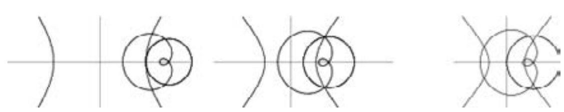
For a HYPERBOLA with $a = b$ with INVERSION CENTER

at the center, the INVERSE CURVE

$$x = \frac{2k \cos t}{a[3 - \cos(2t)]} \quad (1)$$

$$y = \frac{k \sin(2t)}{a[3 - \cos(2t)]} \quad (2)$$

is a LEMNISCATE.

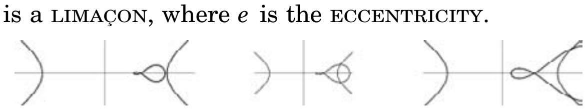


For an INVERSION CENTER at the VERTEX, the INVERSE CURVE

$$x = a + \frac{4k \cos t \sin^2\left(\frac{1}{2}t\right)}{a[5 - 4\cos t + \cos(2t) - 2\sin(2t)]} \quad (3)$$

$$y = a + \frac{k(\tan t - 1)}{a[(\sec t - 1)^2 + (\tan t - 1)^2]} \quad (4)$$

is a RIGHT STROPHOID.



For an INVERSION CENTER at the FOCUS, the INVERSE CURVE

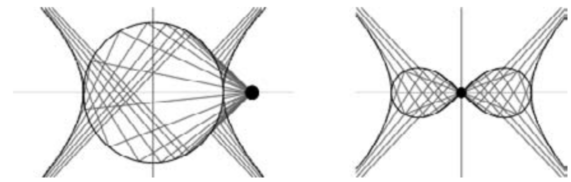
$$x = ae = \frac{k \cos t(1 - e\cos t)}{a(\cos t - e)^2} \quad (5)$$

$$y = \frac{\sqrt{e^2 - 1}\, k \sin(2t)}{2a(\cos t - e)^2} \quad (6)$$

is a LIMAÇON, where e is the ECCENTRICITY.

For a HYPERBOLA with $a = \sqrt{3}b$ and INVERSION CENTER at the VERTEX, the INVERSE CURVE

$$x = b + \frac{2k \cos t(\sqrt{3} - \cos t)}{b[9 - 4\sqrt{3}\cos t + \cos(2t) - 2\sin(2t)]} \quad (7)$$



$$y = b + \frac{k(\tan t - 1)}{b\left[\left(\sqrt{3}\sec t - 1\right)^2 + (\tan t - 1)^2\right]} \quad (8)$$

is a MACLAURIN TRISECTRIX.

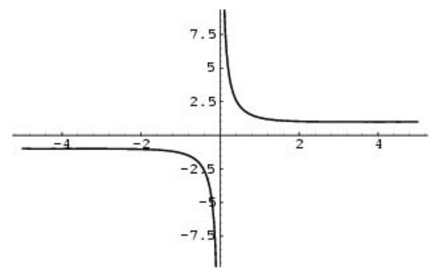
Hyperbolic Cosine

The hyperbolic cosine is defined as

$$\cosh x \equiv \tfrac{1}{2}(e^x + e^{-x}).$$



The notation ch x is sometimes also used (Gradshteyn and Ryzhik 2000, p. xxix). This function describes the shape of a hanging cable, known as the CATENARY.

Hyperbolic Functions

The hyperbolic functions sinh, cosh, tanh, csch, sech, coth (HYPERBOLIC SINE, HYPERBOLIC COSINE, etc.) share many properties with the corresponding CIRCULAR FUNCTIONS. The hyperbolic functions arise in many problems of mathematics and mathematical physics in which integrals involving $\sqrt{1+x^2}$ arise (whereas the CIRCULAR FUNCTIONS involve $\sqrt{1-x^2}$).

For instance, the HYPERBOLIC SINE arises in the gravitational potential of a cylinder and the calculation of the Roche limit. The HYPERBOLIC COSINE function is the shape of a hanging cable (the so-called CATENARY). The HYPERBOLIC TANGENT arises in the calculation of magnetic moment and rapidity of special relativity. All three appear in the Schwarzschild metric using external isotropic Kruskal coordinates in general relativity. The HYPERBOLIC SECANT arises in the profile of a laminar jet. The HYPERBOLIC COTANGENT arises in the Langevin function for magnetic polarization.

The hyperbolic functions are defined by

$$\sinh z \equiv \frac{e^z-e^{-z}}{2} = -\sinh(-z) \tag{1}$$

$$\cosh z \equiv \frac{e^z+e^{-z}}{2} = \cosh(-z) \tag{2}$$

$$\tanh z \equiv \frac{e^z-e^{-z}}{e^z+e^{-z}} = \frac{e^{2z}-1}{e^{2z}+1} \tag{3}$$

$$\operatorname{csch} z \equiv \frac{2}{e^z-e^{-z}} \tag{4}$$

$$\operatorname{sech} z \equiv \frac{2}{e^z+e^{-z}} \tag{5}$$

$$\coth z \equiv \frac{e^z+e^{-z}}{e^z-e^{-z}} = \frac{e^{2z}+1}{e^{2z}-1}. \tag{6}$$

For purely IMAGINARY arguments,

$$\sinh(iz) = i\sin z \tag{7}$$

$$\cosh(iz) = \cos z. \tag{8}$$

The hyperbolic functions satisfy many identities analogous to the trigonometric identities (which can be inferred using OSBORNE'S RULE) such as

$$\cosh^2 x - \sinh^2 x = 1 \tag{9}$$

$$\cosh x + \sinh x = e^x \tag{10}$$

$$\cosh x - \sinh x = e^{-x}. \tag{11}$$

See also Beyer (1987, p. 168). Some HALF-ANGLE FORMULAS are

$$\tanh\left(\frac{z}{2}\right) = \frac{\sinh x + i\sin y}{\cosh x + \cos y} \tag{12}$$

$$\coth\left(\frac{z}{2}\right) = \frac{\sinh x - i\sin y}{\cosh x - \cos y}. \tag{13}$$

Some DOUBLE-ANGLE FORMULAS are

$$\sinh(2x) = 2\sinh x\cosh x \tag{14}$$

$$\cosh(2x) = 2\cosh^2 x - 1 = 1 + 2\sinh^2 x \tag{15}$$

Identities for COMPLEX arguments include

$$\sinh(x+iy) = \sinh x\cosh y + i\cosh x\sin y \tag{16}$$

$$\cosh(x+iy) = \cosh x\cos y + i\sinh x\sin y. \tag{17}$$

The ABSOLUTE SQUARES for COMPLEX arguments are

$$|\sinh(z)|^2 = \sinh^2 x + \sin^2 y \tag{18}$$

$$|\cosh(z)|^2 = \sinh^2 x + \cos^2 y. \tag{19}$$

Integrals involving hyperbolic functions include

$$\int \frac{dx}{x\sqrt{a+bx}} = \ln\left|\frac{\sqrt{a+bx}-\sqrt{a}}{\sqrt{a+bx}+\sqrt{a}}\right| \tag{20}$$

$$= \ln\left|\frac{(\sqrt{a+bx}-\sqrt{a})^2}{(a+bx)-a}\right|$$

$$= \ln\left|\frac{(a+bx)-2\sqrt{a(a+bx)}+a}{bx}\right|. \tag{21}$$

If $b>0$, then

$$\int \frac{dx}{x\sqrt{a+bx}} = \ln\left|\frac{2a+bx-2\sqrt{a(a+bx)}}{bx}\right| \tag{22}$$

$$= \ln\left|\left(\frac{2a}{bx}+1\right) - 2\sqrt{\frac{a}{bx}\left(\frac{a}{bx}+1\right)}\right|. \tag{23}$$

Let $z \equiv 2a/bx+1$, and $a/bx = (z-1)/2$ and

$$\int \frac{dx}{x\sqrt{a+bx}} = \ln\left[z - 2\sqrt{\tfrac{1}{2}(z-1)\tfrac{1}{2}(z+1)}\right]$$

$$= \ln\left[z - \sqrt{(z-1)(z+1)}\right] \tag{24}$$

$$= \ln\left(z - \sqrt{z^2-1}\right) = \cosh^{-1}(z) \tag{25}$$

$$= \cosh^{-1}\left(1 + \frac{2a}{bx}\right) \tag{26}$$

$$= 2 \tanh\left(-\sqrt{\frac{a}{a+bx}}\right). \qquad (27)$$

Hyperbolic Geometry

A NON-EUCLIDEAN GEOMETRY, also called LOBACHEVSKY-BOLYAI-GAUSS GEOMETRY, having constant SECTIONAL CURVATURE -1. This GEOMETRY satisfies all of EUCLID'S POSTULATES *except* the PARALLEL POSTULATE, which is modified to read: For any infinite straight LINE L and any POINT P not on it, there are *many other* infinitely extending straight LINES that pass through P and which do not intersect L.

In hyperbolic geometry, the sum of ANGLES of a TRIANGLE is less than 180°, and TRIANGLES with the same angles have the same areas. Furthermore, not all TRIANGLES have the same ANGLE sum (cf. the AAA THEOREM for TRIANGLES in Euclidean 2-space). There are no similar triangles in hyperbolic geometry. The best-known example of a hyperbolic space are SPHERES in Lorentzian 4-space. The POINCARÉ HYPERBOLIC DISK is a hyperbolic 2-space. Hyperbolic geometry is well understood in 2-D, but not in 3-D.

Geometric models of hyperbolic geometry include the KLEIN-BELTRAMI MODEL, which consists of an OPEN DISK in the Euclidean plane whose open chords correspond to hyperbolic lines. A 2-D model is the POINCARÉ HYPERBOLIC DISK. Felix Klein constructed an analytic hyperbolic geometry in 1870 in which a POINT is represented by a pair of REAL NUMBERS (x_1, x_2) with

$$x_1^2 + x_2^2 < 1$$

(i.e., points of an OPEN DISK in the COMPLEX PLANE) and the distance between two points is given by

$$d(x, X) = a \cosh^{-1}\left[\frac{1 - x_1X_1 - x_2X_2}{\sqrt{1 - x_1^2 - x_2^2}\sqrt{1 - X_1^2 - X_2^2}}\right].$$

The geometry generated by this formula satisfies all of EUCLID'S POSTULATES except the fifth. The METRIC of this geometry is given by the CAYLEY-KLEIN-HILBERT METRIC,

$$g_{11} = \frac{a^2(1 - x_2^2)}{(1 - x_1^2 - x_2^2)^2}$$

$$g_{12} = \frac{a^2 x_1 x_2}{(1 - x_1^2 - x_2^2)^2}$$

$$g_{22} = \frac{a^2(1 - x_1^2)}{(1 - x_1^2 - x_2^2)^2}.$$

Hilbert extended the definition to general bounded sets in a EUCLIDEAN SPACE.

Hyperbolic Inverse Functions

INVERSE HYPERBOLIC FUNCTIONS

Hyperbolic Knot

A hyperbolic knot is a KNOT that has a complement that can be given a metric of constant curvature -1. All hyperbolic knots are PRIME KNOTS (Hoste *et al.* 1998).

KNOTS which are not hyperbolic are either TORUS KNOTS or SATELLITE KNOTS, as proved by Thurston in 1978. Of the prime knots with 16 or fewer crossings, all but 32 are hyperbolic. Of these 32, 12 are torus knots and the remaining 20 are satellites of the TREFOIL KNOT (Hoste *et al.* 1998). The nonhyperbolic knots with nine or fewer crossings are all torus knots, including 03-01 (the (3, 2)-TORUS KNOT), 05-01, 07-01, 08-19 (the (4, 3)-TORUS KNOT), and 09-01.

The following table gives the number of nonhyperbolic and hyperbolic knots of n crossing starting with $n = 3$.

type	Sloane	counts
torus	A051764	1, 0, 1, 0, 1, 1, 1, 1, 1, 0, 1, 1, 2, 1
satellite	A051765	0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 2, 2, 6, 10
nonhyperbolic	A052407	1, 0, 1, 0, 1, 1, 1, 1, 1, 0, 3, 3, 8, 11
hyperbolic	A052408	0, 1, 1, 3, 6, 20, 48, 164, 551, 2176, 9985, 46969, 253285, 1388694

Almost all hyperbolic knots can be distinguished by their hyperbolic volumes (exceptions being 05-02 and a certain 12-crossing knot; see Adams 1994, p. 124). It has been conjectured that the smallest hyperbolic volume is 2.0298..., that of the FIGURE-OF-EIGHT KNOT. MUTANT KNOTS have the same hyperbolic knot volume.

The KNOT SYMMETRY group of a hyperbolic knot must be either a finite CYCLIC GROUP or a finite DIHEDRAL GROUP (Riley 1979, Kodama and Sakuma 1992, Hoste *et al.* 1998).

Hyperbolic Lemniscate Function

By analogy with the LEMNISCATE FUNCTIONS, hyperbolic lemniscate functions can also be defined

$$\operatorname{arcsinhlemn} x \equiv \int_0^x (1+t^4)^{1/2}\, dt \tag{1}$$

$$\operatorname{arccoshlemn} x \equiv \int_0^1 (1+t^4)^{1/2}\, dt. \tag{2}$$

Let $0 \le \theta \le \pi/2$ and $0 \le v \le 1$, and write

$$\frac{\theta\mu}{2} = \int_0^v \frac{dt}{\sqrt{1+t^2}}, \tag{3}$$

where μ is the constant obtained by setting $\theta = \pi/2$ and $v = 1$. Then

$$\mu = \frac{2}{\pi} K\left(\frac{1}{\sqrt{2}}\right), \tag{4}$$

where $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND, and Ramanujan showed

$$2 \tan^{-1} v = \theta + \sum_{n=1}^{\infty} \frac{\sin(2n\theta)}{n \cosh(n\pi)}, \tag{5}$$

$$\tfrac{1}{8}\pi - \tfrac{1}{2}\tan^{-1}(v^2) = \sum_{n=0}^{\infty} \frac{(-1)^n \cos[(2n+1)\theta]}{(2n+1)\cosh\left[\tfrac{1}{2}(2n+1)\pi\right]} \tag{6}$$

and

$$\ln\left(\frac{1+v}{1-v}\right) = \ln\left[\tan\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\theta\right)\right] + 4\sum_{n=0}^{\infty} \frac{(-1)^n \sin[(2n+1)\theta]}{(2n+1)[e^{(2n+1)\pi} - 1]} \tag{7}$$

(Berndt 1994).

Hyperbolic Map

A linear MAP $\mathbb{R}^n$ is hyperbolic if none of its EIGENVALUES has modulus 1. This means that $\mathbb{R}^n$ can be written as a DIRECT SUM of two A-invariant SUBSPACES E^s and E^u (where s stands for stable and u for unstable). This means that there exist constants $C > 0$ and $0 < \lambda < 1$ such that

$$\|A^n v\| \le C\lambda^n \|v\| \quad \text{if } v \in E^s$$

$$\|A^{-n} v\| \le C\lambda^n \|v\| \quad \text{if } v \in E^u$$

for $n = 0, 1, ...$

Bear, H. S. "Part Metric and Hyperbolic Metric." *Amer. Math. Monthly* **98**, 109–23, 1991.

Hyperbolic Octahedron

A hyperbolic version of the Euclidean OCTAHEDRON, which is a special case of the ASTROIDAL ELLIPSOID with $a = b = c = 1$. It is given by the PARAMETRIC EQUATIONS

$$x = (\cos u \cos v)^3$$

$$y = (\sin u \cos v)^3$$

$$z = \sin^3 v$$

for $u \in [-\pi/2, \pi/2]$ and $v \in [-\pi, \pi]$.
The FIRST FUNDAMENTAL FORM coefficients are

$$E = 9a^6 \cos^2 u \sin^2 u \cos^6 v \tag{1}$$

$$F = \tfrac{9}{4} a^6 \cos^5 v \sin v \sin(4u) \tag{2}$$

$$G = 9a^6 \cos^2 v \sin^2 v[\cos^2 v(\cos^6 u + \sin^6 u) + \sin^2 v], \tag{3}$$

the SECOND FUNDAMENTAL FORM coefficients are

$$e = \frac{24a^3 \cos^2 u \sin^2 u \csc(2u)\cos^3 v \sin v}{\sqrt{9 - \cos(4u) - [7 + \cos(4u)]\cos(2v)}} \tag{4}$$

$$f = 0 \tag{5}$$

$$g = \frac{24a^3 \cos^2 u \sin^2 u \csc(2u)\cos^3 v \sin v}{\sqrt{9 - \cos(4u) - [7 + \cos(4u)]\cos(2v)}}, \tag{6}$$

the AREA ELEMENT is

$$dA = \tfrac{9}{8} a^6 \cos^4 v \sin v \sin(2u)$$

$$\times\sqrt{9-\cos(4u)-[7+\cos(4u)\cos(2v)}, \quad (7)$$

and the GAUSSIAN CURVATURE is

$$K = \frac{256 \sec^4 v}{9a^6\{[7+\cos(4u)]\cos(2v)+\cos(4u)-9\}^2}. \quad (8)$$

The MEAN CURVATURE is given by a complicated expression.

Hyperbolic Paraboloid

The QUADRATIC and DOUBLY RULED SURFACE given by the Cartesian equation

$$z = \frac{y^2}{b^2} - \frac{x^2}{a^2} \quad (1)$$

(left figure). An alternative form is

$$z = xy \quad (2)$$

(right figure; Fischer 1986), which has PARAMETRIC EQUATIONS

$$x(u, v) = u \quad (3)$$

$$y(u, v) = v \quad (4)$$

$$z(u, v) = uv \quad (5)$$

(Gray 1997, pp. 297–98).

The coefficients of the FIRST FUNDAMENTAL FORM are

$$E = 1 + v^2 \quad (6)$$

$$F = uv \quad (7)$$

$$G = 1 + u^2, \quad (8)$$

and the SECOND FUNDAMENTAL FORM coefficients are

$$e = 0 \quad (9)$$

$$f = (1 + u^2 + v^2)^{-1/2} \quad (10)$$

$$g = 0, \quad (11)$$

giving SURFACE AREA element

$$dS = \sqrt{1 + u^2 + v^2}. \quad (12)$$

The GAUSSIAN CURVATURE is

$$K = -(1 + u^2 + v^2)^{-2} \quad (13)$$

and the MEAN CURVATURE is

$$H = \frac{uv}{(1 + u^2 + v^2)^{3/2}}. \quad (14)$$

Three skew lines always define a one-sheeted HYPERBOLOID, except in the case where they are all parallel to a single PLANE but not to each other. In this case, they determine a hyperbolic paraboloid (Hilbert and Cohn-Vossen 1999, p. 15).

Hyperbolic Partial Differential Equation

A PARTIAL DIFFERENTIAL EQUATION of second-order, i.e., one OF THE FORM

$$Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + F = 0, \quad (1)$$

is called hyperbolic if the MATRIX

$$\mathsf{Z} \equiv \begin{bmatrix} A & B \\ B & C \end{bmatrix} \quad (2)$$

satisfies $\det(\mathsf{Z}) < 0$. The WAVE EQUATION is an example of a hyperbolic partial differential equation. Initial-boundary conditions are used to give

$$u(x, y, t) = g(x, y, t) \quad \text{for } x \in \partial\Omega,\ t > 0 \quad (3)$$

$$u(x, y, 0) = v_0(x, y) \quad \text{in } \Omega \quad (4)$$

$$u_t(x, y, 0) = v_1(x, y) \quad \text{in } \Omega, \quad (5)$$

where

$$u_{xy} = f(u_x, u_t, x, y) \quad (6)$$

holds in Ω.

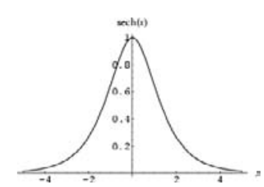
Hyperbolic Rotation

Also known as the a Lorentz transformation or Procrustian stretch, a hyperbolic transformation leaves each branch of the HYPERBOLA $x'y' = xy$ invariant and transforms CIRCLES into ELLIPSES with the same AREA.

$$x' = \mu^{-1} x$$



$$y' = \mu y.$$

Hyperbolic Secant

The hyperbolic secant is defined as

$$\operatorname{sech} x \equiv \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}}, \tag{1}$$

where $\cosh x$ is the HYPERBOLIC COSINE. It has a MAXIMUM at $x = 0$ and inflection points at $x = \pm\operatorname{sech}^{-1}(1\sqrt{2}) \approx 0.881374$.

Equating coefficients of θ^0, θ^4, and θ^8 in the RAMANUJAN COS/COSH IDENTITY

$$\left[1 + 2\sum_{n=1}^{\infty} \frac{\cos(n\theta)}{\cosh(n\pi)}\right]^{-2} + \left[1 + 2\sum_{n=1}^{\infty} \frac{\cosh(n\theta)}{\cosh(n\pi)}\right]^{-2} = \frac{2\Gamma^4\left(\frac{3}{4}\right)}{\pi} \tag{2}$$

gives the amazing identities

$$\sum_{n=1}^{\infty} \operatorname{sech}(\pi n) = \frac{1}{2}\left\{\frac{\sqrt{\pi}}{\left[\Gamma\left(\frac{3}{4}\right)\right]^2} - 1\right\} \tag{3}$$

$$\sum_{n=1}^{\infty} n^4 \operatorname{sech}(\pi n) = \frac{18\left[\Gamma\left(\frac{3}{4}\right)\right]^2}{\sqrt{\pi}}\left[\sum_{n=1}^{\infty} n^2 \operatorname{sech}(\pi n)\right]^2 \tag{4}$$

$$\sum_{n=1}^{\infty} n^8 \operatorname{sech}(\pi n) = \frac{168[\Gamma(\frac{3}{4})]^2}{\sqrt{\pi}}\left[\sum_{n=1}^{\infty} n^2 \operatorname{sech}(\pi n)\right]\sum_{n=1}^{\infty} n^6 \operatorname{sech}(\pi n) - \frac{63000[\Gamma(\frac{3}{4})]^6}{\pi^{3/2}}\left[\sum_{n=1}^{\infty} n^2 \operatorname{sech}(\pi n)\right]^4. \tag{5}$$

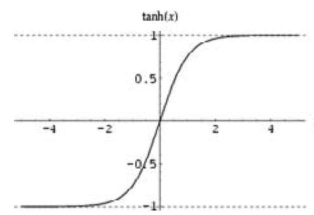
Hyperbolic Spiral Inverse Curve

Taking the pole as the INVERSION CENTER, the HYPERBOLIC SPIRAL inverts to ARCHIMEDES' SPIRAL

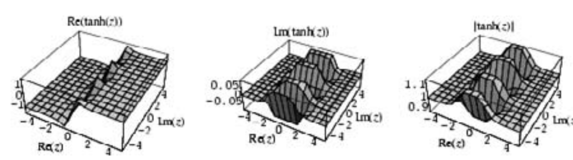
$$r = a\theta.$$

Hyperbolic Spiral Roulette

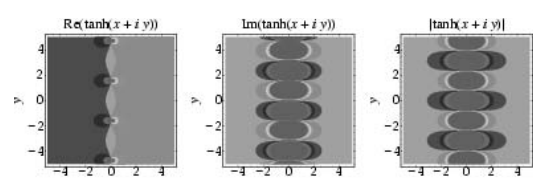
The ROULETTE of the pole of a HYPERBOLIC SPIRAL rolling on a straight line is a TRACTRIX.



Hyperbolic Substitution



A substitution which can be used to transform integrals involving square roots into a more tractable form.



Form	Substitution
$\sqrt{x^2+a^2}$	$x = a \sinh u$
$\sqrt{x^2-a^2}$	$x = a \cosh u$

See also INTEGRAL, TRIGONOMETRIC SUBSTITUTION

Hyperbolic Tangent

By way of analogy with the usual TANGENT

$$\tan x \equiv \frac{\sin x}{\cos x},$$

the hyperbolic tangent is defined as

$$\tanh x \equiv \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}} = \frac{e^{2x} - 1}{e^{2x} + 1},$$

where $\sinh x$ is the HYPERBOLIC SINE and $\cosh x$ is the HYPERBOLIC COSINE. The notation th x is sometimes also used (Gradshteyn and Ryzhik 2000, p. xxix).

The hyperbolic tangent can be written using a CONTINUED FRACTION as

$$\tanh x = \cfrac{x}{1 + \cfrac{x^2}{3 + \cfrac{x^3}{5 + \cdots}}}.$$

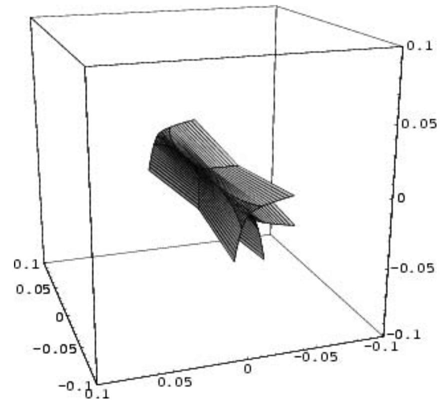
Hyperbolic Tetrahedron

A hyperbolic version of the Euclidean TETRAHEDRON.



See also HYPERBOLIC CUBE, HYPERBOLIC DODECAHEDRON, HYPERBOLIC ICOSAHEDRON, HYPERBOLIC OCTAHEDRON, REULEAUX TETRAHEDRON

References

Rivin, I. "Hyperbolic Polyhedron Graphics." http://www.mathsource.com/cgi-bin/msitem22?0201–88.

Trott, M. "The Cover Image: Hyperbolic Platonic Bodies." §8.3.10 in *The Mathematica Guidebook, Vol. 2: Graphics in Mathematica.* New York: Springer-Verlag, 2000.

Hyperbolic Umbilic Catastrophe

A CATASTROPHE which can occur for three control factors and two behavior axes. The hyperbolic umbilic is the universal unfolding of the function germ $f(x, y) = x^3 + y^3$. The CODIMENSION of f is 3, and therefore the universal unfolding F of f has three unfolding parameters.

See also CATASTROPHE THEORY, ELLIPTIC UMBILIC CATASTROPHE

References

Sanns, W. *Catastrophe Theory with Mathematica: A Geometric Approach.* Germany: DAV, 2000.

Hyperboloid

A QUADRATIC SURFACE which may be one- or two-sheeted. The one-sheeted hyperboloid is a SURFACE OF REVOLUTION obtained by rotating a HYPERBOLA about the perpendicular bisector to the line between the FOCI, while the two-sheeted hyperboloid is a SURFACE OF REVOLUTION obtained by rotating a HYPERBOLA about the line joining the FOCI (Hilbert and Cohn-Vossen 1991, p. 11).

The one-sheeted circular hyperboloid is a DOUBLY RULED SURFACE. When oriented along the Z-AXIS, the one-sheeted circular hyperboloid has CARTESIAN COORDINATES equation

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} - \frac{z^2}{c^2} = 1, \tag{1}$$

and parametric equation

$$x = a\sqrt{1+u^2}\cos v \tag{2}$$

$$y = a\sqrt{1+u^2}\sin v \tag{3}$$

$$z = cu \tag{4}$$

for $v \in [0, 2\pi)$ (left figure). Other parameterizations include

$$x(u, v) = a(\cos u \mp v \sin u) \tag{5}$$

$$y(u, v) = a(\sin u \pm v \sin u) \tag{6}$$

$$z(u, v) = \pm cv, \tag{7}$$

(middle figure), or

$$x(u, v) = a \cosh v \cos u \tag{8}$$

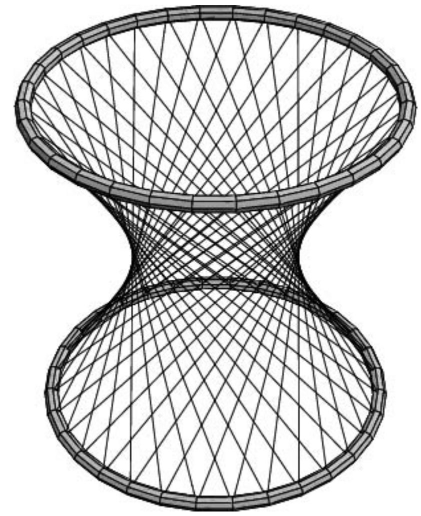
$$y(u, v) = a \cosh v \sin u \tag{9}$$

$$z(u, v) = c \sinh v \tag{10}$$

(right figure).

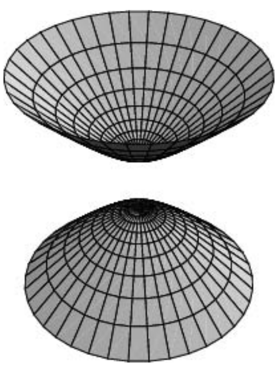
A hyperboloid of one sheet is also obtained as the envelope of a CUBE rotated about a space diagonal (Steinhaus 1983, pp. 171–72). Three skew lines always define a one-sheeted hyperboloid, except in the case where they are all parallel to a single PLANE but not to each other (Hilbert and Cohn-Vossen 1999, p. 15).

The VOLUME of a one-sheeted hyperboloid of height h, waist radius a, and top and bottom radii R is



$$V = \pi h a^2\left(1+\frac{h^2}{12b^2}\right) \tag{11}$$

$$= \tfrac{1}{3}\pi h(2a^2+R^2), \tag{12}$$



where

$$R^2 = a^2\left(1+\frac{h^2}{4b^2}\right) \tag{13}$$

(Harris and Stocker 1998). An obvious generalization gives the one-sheeted ELLIPTIC HYPERBOLOID.

The hyperboloid of one sheet can be constructed by connecting two concentric vertically offset rings wire tilted wires, as illustrated above (Steinhaus 1983, pp. 242–43; Hilbert and Cohn-Vossen 1999, p. 11). Surprisingly, when the wires are fastened together so that rotation but not sliding is permitted, the framework can be expanded and collapsed as one ring is rotated relative to the other (Hilbert and Cohn-Vossen 1999, pp. 16–7 and 29–1).

A two-sheeted circular hyperboloid oriented along the z-AXIS has CARTESIAN COORDINATES equation

$$\frac{x^2}{a^2}+\frac{y^2}{a^2}-\frac{z^2}{c^2} = -1. \tag{14}$$

The PARAMETRIC EQUATIONS are

$$x = a \sinh u \cos v \tag{15}$$

$$y = a \sinh u \sin v \tag{16}$$

$$z = \pm c \cosh u \tag{17}$$

for $v \in [0, 2\pi)$. Note that the plus and minus signs in z correspond to the upper and lower sheets. The two-sheeted circular hyperboloid oriented along the x-AXIS has Cartesian equation

$$\frac{x^2}{a^2} - \frac{y^2}{a^2} - \frac{z^2}{c^2} = 1 \tag{18}$$

and PARAMETRIC EQUATIONS

$$x = \pm a \cosh u \cosh v \tag{19}$$

$$y = a \sinh u \cosh v \tag{20}$$

$$z = c \sinh v \tag{21}$$

(Gray 1997, p. 406). The VOLUME of a two-sheeted hyperboloid of half-separation a, height h, and radius R is

$$V = \frac{2\pi h^2 b^2}{a^2}(a + \tfrac{1}{3}h) \tag{22}$$

$$= \pi h \left(R^2 - \frac{h^2 b^2}{3a^2}\right), \tag{23}$$

where

$$R^2 = \frac{hb^2}{a^2}(2a + h) \tag{24}$$

(Harris and Stocket 1998). Again, an obvious generalization gives the two-sheeted ELLIPTIC HYPERBOLOID.

The SUPPORT FUNCTION of the hyperboloid of one sheet

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1 \tag{25}$$

is

$$h = \left(\frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{c^4}\right)^{-1/2}, \tag{26}$$

and the GAUSSIAN CURVATURE is

$$K = -\frac{h^4}{a^2 b^2 c^2}. \tag{27}$$

The SUPPORT FUNCTION of the hyperboloid of two sheets

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1 \tag{28}$$

is

$$h = \left(\frac{x^2}{a^4} - \frac{y^2}{b^4} + \frac{z^2}{c^4}\right)^{-1/2}, \tag{29}$$

and the GAUSSIAN CURVATURE is

$$K = \frac{h^4}{a^2 b^2 c^2} \tag{30}$$

(Gray 1997, p. 414).

Hyperboloid Embedding

A 4-HYPERBOLOID has NEGATIVE CURVATURE, with

$$R^2 = x^2 + y^2 + z^2 - w^2 \tag{1}$$

$$2x\frac{dx}{dw} + 2y\frac{dy}{dw} + 2z\frac{dz}{dw} - 2w = 0. \tag{2}$$

Since

$$\mathbf{r} \equiv x\hat{\mathbf{x}} + y\hat{\mathbf{y}} + z\hat{\mathbf{z}}, \tag{3}$$

$$dw = \frac{x\,dx + y\,dy + z\,dz}{w} = \frac{\mathbf{r} \cdot d\mathbf{r}}{\sqrt{r^2 - R^2}}. \tag{4}$$

To stay on the surface of the HYPERBOLOID, the LINE ELEMENT is given by

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 - dw^2 \\ &= dx^2 + dy^2 + dz^2 - \frac{r^2\,dr^2}{r^2 - R^2} \\ &= dr^2 + r^2\,d\Omega^2 + \frac{dr^2}{1 - \frac{R^2}{r^2}}. \end{aligned} \tag{5}$$

Hypercomplex Number

There are at least two definitions of hypercomplex numbers. CLIFFORD ALGEBRAISTS call their higher dimensional numbers hypercomplex, even though they do not share all the properties of complex numbers and no classical function theory can be constructed over them.

According to van der Waerden (1985), a hypercomplex number is a number having properties departing from those of the REAL and COMPLEX NUMBERS. The most common examples are BIQUATERNIONS, EXTERIOR ALGEBRAS, GROUP algebras, MATRICES, OCTONIONS, and QUATERNIONS. One type of hypercomplex number due to Davenport (1996) and sometimes called "the" hypercomplex numbers are defined according to the multiplication table

$$ij = ji = k \tag{1}$$

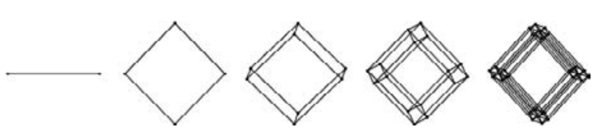
$$jk = kj = -i \tag{2}$$

$$ki = ik = -j, \tag{3}$$

and therefore satisfy

$$i^2 = j^2 = -1 \tag{4}$$

$$k^2 = 1. \tag{5}$$



Unlike QUATERNIONS, multiplication of these hypercomplex numbers *is* commutative, and unlike real and complex numbers, not all nonzero hypercomplex numbers have a multiplicative inverse. An application of this sort of hypercomplex number can be found in the `julia_fractal` command in *POVRay*.

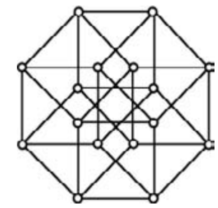
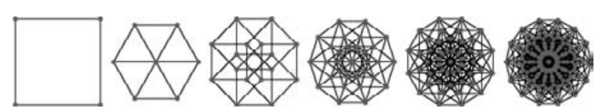
Hypercube



The generalization of a 3-CUBE to n-D, also called a MEASURE POLYTOPE. It is a regular POLYTOPE with mutually PERPENDICULAR sides, and is therefore an ORTHOTOPE. It is denoted γ_n and has SCHLÄFLI SYMBOL



$$\{4, \underbrace{3, 3}_{n-2}\}.$$

The number of k-cubes contained in an n-cube can be found from the COEFFICIENTS of $(2k+1)^n$.

The 1-hypercube is a LINE SEGMENT, the 2-hypercube is the SQUARE, and the 3-hypercube is the CUBE. The hypercube in $\mathbb{R}^4$, called a TESSERACT, has the SCHLÄFLI SYMBOL $\{4, 3, 3\}$ and VERTICES $(\pm 1, \pm 1, \pm 1, \pm 1)$. The above figures show two visualizations of the TESSERACT. The figure on the left is a projection of the TESSERACT in 3-space (Gardner 1977; Williams 1979, p. 26), which also appears on the cover of Born (1926), and the figure on the right is the GRAPH of the TESSERACT symmetrically projected into the PLANE (Coxeter 1973). A TESSERACT has 16 VERTICES, 32 EDGES, 24 SQUARES, and eight CUBES. The dual of the 4-hypercube is the 16-CELL.

The above figures show the graphs for the n-hypercubes with $n = 2$ to 7. All hypercubes are HAMILTONIAN, and any HAMILTONIAN CIRCUIT of a labeled hypercube defines a GRAY CODE (Skiena 1990, p. 149).

Hypercube Line Picking

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let two points **x** and **y** be picked randomly from a unit n-dimensional HYPERCUBE. The expected distance between the points $\Delta(N)$ is then

$$\Delta(N) = \underbrace{\int_0^1 \cdots \int_0^1}_{2n} [(x_1-y_1)^2 + (x_2-y_2)^2 + \ldots + (x_n+y_n)]^{1/2}\, dx_1 \cdots dx_n dy_1 \ldots dy_n. \quad (1)$$

This MULTIPLE INTEGRAL has been evaluated analytically only for small values of n. The case $\Delta(1)$ corresponds to the POINT-POINT DISTANCE between two random points in the interval $[0, 1]$.

The function $\Delta(n)$ satisfies

$$\tfrac{1}{3} n^{1/2} \leq \Delta(n) \leq \left(\tfrac{1}{6} n\right)^{1/2} \sqrt{\frac{1}{3}\left[1+2\left(1-\frac{3}{5n}\right)^{1/2}\right]} \quad (2)$$

(Anderssen *et al.* 1976). The first few numerical and analytic results for $\Delta(n)$ are

$$\Delta(1) = \tfrac{1}{3}$$

$$\Delta(2) = \tfrac{1}{15}[\sqrt{2}+2+5\ln(1+\sqrt{2})] = 0.521405433\ldots$$

$$\Delta(3) = \tfrac{1}{105}[4+17\sqrt{2}-6\sqrt{3}+21\ln(1+\sqrt{2}) + 42\ln(2+\sqrt{3})-7\pi] = 0.661707182\ldots$$

$$\Delta(4) = 0.77766\ldots$$

$$\Delta(5) = 0.87852\ldots$$

$$\Delta(6) = 0.96895\ldots$$

$$\Delta(7) = 1.05159\ldots$$

$$\Delta(8) = 1.12817\ldots$$

Hypercube Triangulation

References

Finch, S. "Unsolved Mathematics Problems: Triangulating an n-Dimensional Cube." http://www.mathsoft.com/asolve/simplex/simplex.html.

Hyperdeterminant

A technically defined extension of the ordinary DETERMINANT to "higher dimensional" HYPERMATRICES. Cayley (1845) originally coined the term, but subsequently used it to refer to an ALGEBRAIC INVARIANT of a multilinear form. The hyperdeterminant of the $2 \times 2 \times 2$ HYPERMATRIX $A = a_{ijk}$ (for $i, j, k = 0, 1$) is given by

$$\begin{aligned}\det(A) = {} & (a_{000}^2 a_{111}^2 + a_{001}^2 a_{110}^2 + a_{010}^2 a_{101}^2 + a_{011}^2 a_{100}^2) \\ & -2(a_{000}a_{001}a_{110}a_{111} + a_{000}a_{010}a_{101}a_{111} + a_{000}a_{011}a_{100}a_{111} \\ & + a_{001}a_{010}a_{101}a_{110} + a_{001}a_{011}a_{110}a_{100} + a_{010}a_{011}a_{101}a_{100}) \\ & +4(a_{000}a_{011}a_{101}a_{110} + a_{001}a_{010}a_{100}a_{111}).\end{aligned}$$

The above hyperdeterminant vanishes IFF the following system of equations in six unknowns has a nontrivial solution,

$$a_{000}x_0y_0 + a_{010}x_0y_1 + a_{100}x_1y_0 + a_{110}x_1y_1 = 0$$
$$a_{001}x_0y_0 + a_{011}x_0y_1 + a_{101}x_1y_0 + a_{111}x_1y_1 = 0$$
$$a_{000}x_0z_0 + a_{001}x_0z_1 + a_{100}x_1z_0 + a_{101}x_1z_1 = 0$$
$$a_{010}x_0z_0 + a_{011}x_0z_1 + a_{110}x_1z_0 + a_{111}x_1z_1 = 0$$
$$a_{000}y_0z_0 + a_{001}y_0z_1 + a_{010}y_1z_0 + a_{011}y_1z_1 = 0$$
$$a_{100}y_0z_0 + a_{101}y_0z_1 + a_{110}y_1z_0 + a_{111}y_1z_1 = 0.$$

Glynn (1998) has found the only known multiplicative hyperdeterminant in dimension larger than two.

Hyperfinite Set

One of the most useful tools in NONSTANDARD ANALYSIS is the concept of a hyperfinite set. To understand a hyperfinite set, begin with an arbitrary infinite set X whose members are not sets, and form the SUPERSTRUCTURE $S(X)$ over X. Assume that X includes the natural numbers as elements, let $\mathbb{N}$ denote the set of natural numbers as elements of X, and let $^*S(X)$ be an ENLARGEMENT of $S(X)$. By the TRANSFER PRINCIPLE, the ordering $<$ on $\mathbb{N}$ extends to a strict linear ordering on $^*\mathbb{N}$, which can be denoted with the symbol "$<$." Since $^*S(X)$ is an enlargement of $S(X)$, it satisfies the CONCURRENCY PRINCIPLE, so that there is an element ν of $^*\mathbb{N}$ such that if $n \in \mathbb{N}$, then $n < \nu$. This follows because the relation $<$ is a CONCURRENT RELATION on the set of natural numbers.

Any member ν of $^*\mathbb{N}$ is called an infinite nonstandard natural number, and for any set $A \in {}^*S(X)$, if A is in one-to-one correspondence with any element of $^*\mathbb{N}$, then A is called a hyperfinite set in $^*S(X)$. Because there are infinite nonstandard natural numbers in any enlargement $^*S(X)$ of $S(X)$, there are hyperfinite sets that are not finite, in any such enlargement. Such hyperfinite sets can be used to study infinite structures satisfying various finiteness conditions.

Hypergeometric Distribution

Let there be n ways for a successful and m ways for an unsuccessful trial out of a total of $n+m$ possibilities. Take N samples and let x_i equal 1 if selection i is successful and 0 if it is not. Let x be the total number of successful selections,

$$x \equiv \sum_{i=1}^{N} x_i. \tag{1}$$

The probability of i successful selections is then

$$P(x=i) = \frac{[\#\text{ ways for } i \text{ successes}][\#\text{ ways for } N-i \text{ unsuccesses}]}{[\text{total number of ways to select}]}$$

$$= \frac{\binom{n}{i}\binom{m}{N-i}}{\binom{n+m}{N}} = \frac{\frac{n!}{i!(n-i!)}\frac{m!}{(m+i-N)!(N-i)!}}{\frac{(n+m)!}{N!(N-n-m)!}}$$

$$= \frac{n!m!N!(N-m-n)!}{i!(n-i)!(m+i-N)!(N-i)!(n+m)!}. \tag{2}$$

The ith selection has an equal likelihood of being in any trial, so the fraction of acceptable selections p is

$$p \equiv \frac{n}{n+m} \tag{3}$$

$$P(x_i = 1) = \frac{n}{n+m} \equiv p. \tag{4}$$

The expectation value of x is

$$\mu \equiv \langle x \rangle = \left\langle \sum_{i=1}^{N} x_i \right\rangle = \sum_{i=1}^{N} \langle x_i \rangle$$

$$= \sum_{i=1}^{N} \frac{n}{n+m} = \frac{nN}{n+m} = Np. \tag{5}$$

The VARIANCE is

$$\operatorname{var}(x) \equiv \sum_{i=1}^{N} \operatorname{var}(x_i) + \sum_{i=1}^{N} \sum_{\substack{j=1 \\ j\neq 1}}^{N} \operatorname{cov}(x_i, x_j). \tag{6}$$

Since x_i is a BERNOULLI variable,

$$\operatorname{var}(x_i) = p(1-p) = \frac{n}{n+m}\left(1 - \frac{n}{n+m}\right)$$

$$= \frac{n}{n+m}\left(1 - \frac{n}{n+m}\right)$$

$$= \frac{n}{n+m}\left(\frac{n+m-n}{n+m}\right) = \frac{nm}{(n+m)^2}, \tag{7}$$

so

$$\sum_{i=1}^{N} \operatorname{var}(x_i) = \frac{Nnm}{(n+m)^2}. \tag{8}$$

For $i<j$, the COVARIANCE is

$$\operatorname{cov}(x_i, x_j) = \langle x_i x_j \rangle - \langle x_i \rangle \langle x_j \rangle. \tag{9}$$

The probability that both i and j are successful for $i \neq j$ is

$$P(x_i = 1, x_j = 1) = P(x_i = 1) P(x_j = 1 | x_i = 1)$$

$$= \frac{n}{n+m} \frac{n-1}{n+m-1}$$

$$= \frac{n(n-1)}{(n+m)(n+m-1)}. \tag{10}$$

But since x_i and x_j are random BERNOULLI variables (each 0 or 1), their product is also a BERNOULLI variable. In order for $x_i x_j$ to be 1, both x_i and x_j must be 1,

$$\langle x_i x_j \rangle = P(x_i x_j = 1) = P(x_i = 1, x_j = 1)$$

$$= \frac{n}{n+m} \frac{n-1}{n+m-1}$$

$$= \frac{n(n-1)}{(n+m)(n+m-1)}. \tag{11}$$

Combining (11) with

$$\langle x_i \rangle \langle x_j \rangle = \frac{n}{n+m} \frac{n}{n+m} = \frac{n^2}{(n+m)^2}, \tag{12}$$

gives

$$\operatorname{cov}(x_i, x_j) = \frac{(n+m)(n^2-n) - n^2(n+m-1)}{(n+m)^2(n+m-1)}$$

$$= \frac{n^3 + mn^2 - n^2 - mn - n^3 - n^2 m + n^2}{(n+m)^2(n+m-1)}$$

$$= -\frac{mn}{(n+m)^2(n+m-1)}. \tag{13}$$

There are a total of N^2 terms in a double summation

over N. However, $i = j$ for N of these, so there are a total of $N^2 - N = N(N-1)$ terms in the COVARIANCE summation

$$\sum_{i=1}^{N} \sum_{\substack{j=1 \\ j\neq i}}^{n} \operatorname{cov}(x_i, x_j) = -\frac{N(N-1)mn}{(n+m)^2(n+m-1)}. \quad (14)$$

Combining equations (6), (8), (11), and (14) gives the VARIANCE

$$\begin{aligned}\operatorname{var}(x) &= \frac{Nmn}{(n+m)^2} - \frac{N(N-1)mn}{(n+m)^2(n+m-1)} \\ &= \frac{Nmn}{(n+m)^2}\left(1 - \frac{N-1}{n+m-1}\right) \\ &= \frac{Nmn}{(n+m)^2}\left(\frac{N+m-1-N+1}{n+m-1}\right) \\ &= \frac{Nmn(n+m-N)}{(n+m)^2(n+m-1)}, \end{aligned} \quad (15)$$

so the final result is

$$\langle x \rangle = Np \quad (16)$$

and, since

$$1 - p = \frac{m}{n+m} \quad (17)$$

and

$$np(1-p) = \frac{mn}{(n+m)^2}, \quad (18)$$

we have

$$\begin{aligned}\sigma^2 = \operatorname{var}(x) &= Np(1-p)\left(1 - \frac{N-1}{n+m-1}\right) \\ &= \frac{mnN(m+n-N)}{(m+n)^2(m+n-1)}. \end{aligned} \quad (19)$$

The SKEWNESS is

$$\begin{aligned}\gamma_1 &= \frac{q-p}{\sqrt{npq}} \sqrt{\frac{N-1}{N-m}} \left(\frac{N-2n}{N-2}\right) \\ &= \frac{(m-n)(m+n-2N)}{m+n-2} \sqrt{\frac{m+n-1}{mnN(m+n-N)}}, \end{aligned} \quad (20)$$

and the KURTOSIS is given by the complicated expression

$$\gamma_2 = \frac{F(m, n, N)}{mnN(-3+m+n)(-2+m+n)(-m-n+N)}, \quad (21)$$

where

$$\begin{aligned}F(m, n, N) = {} & m^3 - m^5 + 3m^2n - 6m^3n + m^4n + 3mn^2 \\ & -12m^2n^2 + 8m^3n^2 + n^3 - 6mn^3 + 8m^2n^3 \\ & +mn^4 - n^5 - 6m^3N + 6m^4N + 18m^2nN \\ & -6m^3nN + 18mn^2N - 24m^2n^2N - 6n^3N \\ & -6mn^3N + 6n^4N + 6m^2N^2 - 6m^3N^2 \\ & -24mnN^2 + 12m^2nN^2 + 6n^2N^2 \\ & +12mn^2N^2 - 6n^3N^2. \end{aligned} \quad (22)$$

The GENERATING FUNCTION is

$$\phi(t) = \frac{\binom{m}{N}}{\binom{n+m}{N}} \, {}_2F_1(-N, -n; m-N+1; e^{it}), \quad (23)$$

where ${}_2F_1(a, b; c; z)$ is the HYPERGEOMETRIC FUNCTION.

If the hypergeometric distribution is written

$$h_n(x, s) = \frac{\binom{np}{x}\binom{nq}{s-x}}{\binom{n}{s}}, \quad (24)$$

then

$$\sum_{x=0}^{s} h_n(x, s)u^x = A \, {}_2F_1(-s, -np; nq-s+1; u). \quad (25)$$

Hypergeometric Function

A GENERALIZED HYPERGEOMETRIC FUNCTION ${}_pF_q(a_1, \ldots, a_p; b_1, \ldots, b_q; x)$ is a function which can be defined in the form of a HYPERGEOMETRIC SERIES, i.e., a series for which the ratio of successive terms can be written

$$\begin{aligned}\frac{c_{k+1}}{c_k} &= \frac{P(k)}{Q(k)} \\ &= \frac{(k+a_1)(k+a_2)\cdots(k+a_p)}{(k+b_1)(k+b_2)\cdots(k+b_q)(k+1)} x. \end{aligned} \quad (1)$$

(The factor of $k+1$ in the DENOMINATOR is present for historical reasons of notation.)

The function ${}_2F_1(a, b; c; x)$ corresponding to $p = 2$, $q = 1$ is the first hypergeometric function to be studied (and, in general, arises the most frequently in physical problems), and so is frequently known as "the" hypergeometric equation or, more explicitly, Gauss's hypergeometric function (Gauss 1812; Barnes 1908). To confuse matters even more, the term "hypergeometric function" is less commonly used to mean CLOSED FORM, and "hypergeometric series" is sometimes used to mean hypergeometric function.

The hypergeometric functions are solutions to the HYPERGEOMETRIC DIFFERENTIAL EQUATION, which has a REGULAR SINGULAR POINT at the ORIGIN. To derive the hypergeometric function based on the HYPERGEOMETRIC DIFFERENTIAL EQUATION, plug

$$y = \sum_{n=0}^{\infty} A_n z^n \tag{2}$$

$$y' = \sum_{n=0}^{\infty} nA_n z^{n-1} \tag{3}$$

$$y'' = \sum_{n=0}^{\infty} n(n-1)A_n z^{n-2} \tag{4}$$

into

$$z(1-z)y'' + [c-(a+b+1)z]y' - aby = 0 \tag{5}$$

to obtain

$$\sum_{n=0}^{\infty} n(n-1)A_n z^{n-1} - \sum_{n=0}^{\infty} n(n-1)A_n z^n + c\sum_{n=0}^{\infty} nA_n z^{n-1} + (a+b+1)\sum_{n=0}^{\infty} nA_n z^n - ab\sum_{n=0}^{\infty} A_n z^n = 0 \tag{6}$$

$$\sum_{n=2}^{\infty} n(n-1)A_n z^{n-1} - \sum_{n=0}^{\infty} n(n-1)A_n z^n + c\sum_{n=1}^{\infty} nA_n z^{n-1} - (a+b+1)\sum_{n=1}^{\infty} nA_n z^n - ab\sum_{n=0}^{\infty} A_n z^n = 0 \tag{7}$$

$$\sum_{n=0}^{\infty}(n+1)nA_{n+1}z^n - \sum_{n=0}^{\infty} n(n-1)A_n z^n + c\sum_{n=0}^{\infty}(n+1)A_{n+1}z^n - (a+b+1)\sum_{n=0}^{\infty} nA_n z^n - ab\sum_{n=0}^{\infty} A_n z^n = 0 \tag{8}$$

$$\sum_{n=0}^{\infty}[n(n+1)A_{n+1} - n(n-1)A_n + c(n+1)A_{n-1} \times \sum_{n=0}^{\infty}\{(n+1)(n+c)A_{n+1} - [n(n-1+a+b+1)+ab]A_n\}z^n = 0 \tag{9}$$

$$\sum_{n=0}^{\infty}\{(n+1)(n+c)A_{n+1} - [n^2+(a+b)n+ab]A_n\}z^n = 0, \tag{10}$$

so

$$A_{n+1} = \frac{(n+a)(n+b)}{(n+1)(n+c)} A_n \tag{11}$$

and

$$y = A_0\left[1 + \frac{ab}{1!c}z + \frac{a(a+1)b(b+1)}{2!c(c+1)}z^2 + \ldots\right]. \tag{12}$$

This is the regular solution and is denoted

$${}_2F_1(a, b; c; z) = 1 + \frac{ab}{1!c}z + \frac{a(a+1)b(b+1)}{2!c(c+1)}z^2 + \ldots = \sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{(c)_n}\frac{z^n}{n!}, \tag{13}$$

where $(a)_n$ are POCHHAMMER SYMBOLS. The hypergeometric series is convergent for REAL $-1 < z < 1$, and for $z = \pm 1$ if $c > a + b$. The complete solution to the HYPERGEOMETRIC DIFFERENTIAL EQUATION is

$$y = A\,{}_2F_1(a, b; c; z) + Bz^{1-c}\,{}_2F_1(a+1-c, b+1-c; 2-c; z). \tag{14}$$

Derivatives are given by

$$\frac{d\,{}_2F_1(a, b; c; z)}{dz} = \frac{ab}{c}\,{}_2F_1(a+1, b+1; c+1; z) \tag{15}$$

$$\frac{d^2\,{}_2F_1(a, b; c; z)}{dz^2} = \frac{a(a+1)b(b+1)}{c(c+1)}\,{}_2F_1(a+2, b+2; c+2; z) \tag{16}$$

(Magnus and Oberhettinger 1949, p. 8).

An integral giving the hypergeometric function is

$${}_2F_1(a, b; c; z) = \frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)}\int_0^1 \frac{t^{b-1}(1-t)^{c-b-1}}{(1-tz)^a}\,dt \tag{17}$$

as shown by Euler in 1748 (Bailey 1935, pp. 4–).

Barnes (1908) gave the CONTOUR INTEGRAL

$$ {}_2F_1(a,\ b;\ c;\ z) = \frac{1}{2\pi i}\int_{-i\infty}^{i\infty}\frac{\Gamma(a+s)\Gamma(b+s)\Gamma(-s)}{\Gamma(c-s)}(-z)^s\,ds, \quad (18) $$

where $|\arg(-z)| < \pi$ and the path is curved (if necessary) to separate the poles $s = -a - n$, $s = -b - n$, ... ($n = 0$, 1, ...) from the poles $s = 0$, 1 ... (Bailey 1935, pp. 4–; Whittaker and Watson 1990).

A hypergeometric function can be written using EULER'S HYPERGEOMETRIC TRANSFORMATIONS

$$ t \to t \quad (19) $$

$$ t \to 1-t \quad (20) $$

$$ t \to (1-z-tz)^{-1} \quad (21) $$

$$ t \to \frac{1-t}{1-tz} \quad (22) $$

in any one of four equivalent forms

$$ {}_2F_1(a,\ b;\ c;\ z) = (1-z)^{-a}\,{}_2F_1(a,\ c-b;\ c;\ z/(z-1)) $$

nbsp; (23r$_{\rm p}$ar

$$ = (1-z)^{-b}\,{}_2F_1(c-a, b;\ c;\ z/(z-1)) $$

nbsp; (24r$_{\rm p}$ar

$$ = (1-z)^{c-a-b}\,{}_2F_1(c-a,\ c-b;\ c;\ z) $$

nbsp; (25r$_{\rm p}$ar

It can also be written as a linear combination

$$ {}_2F_1(a,\ b;\ c;\ z) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}\,{}_2F_1(a,\ b;\ a+b+1-c;\ 1-z) + \frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)} \times (1-z)^{c-a-b}\,{}_2F_1(c-a,\ c-b;\ 1+c-a-b;\ 1-z) \quad (26) $$

(Barnes 1908; Bailey 1935, pp. 3–; Whittaker and Watson 1990, p. 291).

Kummer found all six solutions (not necessarily regular at the origin) to the HYPERGEOMETRIC DIFFERENTIAL EQUATION,

$$ u_1(x) = {}_2F_1(a,\ b;\ c;\ z) \quad (27) $$

$$ u_2(x) = {}_2F_1(a,\ b;\ a+b+1-c;\ 1-z) \quad (28) $$

$$ u_3(x) = z^{-a}\,{}_2F_1(a,\ a+1-c;\ a+1-b;\ z^{-1}) \quad (29) $$

$$ u_4(x) = z^{-b}\,{}_2F_1(b+1-c,\ b;\ b+1-a;\ z^{-1}) \quad (30) $$

$$ u_5(x) = z^{1-c}\,{}_2F_1(b+1-c,\ a+1-c;\ 2-c;\ z) \quad (31) $$

$$ u_6(x) = (1-z)^{c-a-b}\,{}_2F_1(c-a,\ c-b;\ c+1-a-b;\ 1-z) \quad (32) $$

(Abramowitz and Stegun 1972, p. 563).

Applying EULER'S HYPERGEOMETRIC TRANSFORMATIONS to the Kummer solutions then gives all 24 possible forms which are solutions to the HYPERGEOMETRIC DIFFERENTIAL EQUATION

$$ u_1^{(1)}(x) = {}_2F_1(a,\ b;\ c;\ z) \quad (33) $$

$$ u_1^{(2)}(x) = (1-z)^{c-a-b}\,{}_2F_1(c-a,\ c-b;\ c;\ z) \quad (34) $$

$$ u_1^{(3)}(x) = (1-z)^{-a}\,{}_2F_1(a,\ c-b;\ c;\ z/(z-1)) \quad (35) $$

$$ u_1^{(4)}(x) = (1-z)^{-b}\,{}_2F_1(c-a,\ b;\ c;\ z/(z-1)) \quad (36) $$

$$ u_2^{(1)}(x) = {}_2F_1(a,\ b;\ a+b+1-c;\ 1-z) \quad (37) $$

$$ u_2^{(2)}(x) = z^{1-c}\,{}_2F_1(a+1-c,\ b+1-c;\ a+b+1-c;\ 1-z) \quad (38) $$

$$ u_2^{(3)}(x) = z^{-a}\,{}_2F_1(a,\ a+1-c;\ a+b+1-c;\ 1-z^{-1}) \quad (39) $$

$$ u_2^{(4)}(x) = z^{-b}\,{}_2F_1(b+1-c,\ b;\ a+b+1-c;\ 1-z^{-1}) \quad (40) $$

$$ u_3^{(1)}(x) = (-z)^{-a}\,{}_2F_1(a,\ a+1-c;\ a+1-b;\ z^{-1}) \quad (41) $$

$$ u_3^{(2)}(x) = (-z)^{b-c} \times (1-z)^{c-a-b}\,{}_2F_1(1-b,\ c-b;\ a+1-b;\ z^{-1}) \quad (42) $$

$$ u_3^{(3)}(x) = (1-z)^{-a}\,{}_2F_1(a,\ c-b;\ a+1-b; (1-z)^{-1}) \quad (43) $$

$$ u_3^{(4)}(x) = (-z)^{1-c} \times (1-z)^{c-a-1}\,{}_2F_1(a+1-c,\ 1-b;\ a+1-b; (1-z)^{-1}) \quad (44) $$

$$ u_4^{(1)}(x) = (-z)^{-b}\,{}_2F_1(b+1-c,\ b;\ b+1-a;\ z^{-1}) \quad (45) $$

$$ u_4^{(2)} = (-z)^{a-c} \times (1-z)^{c-a-b}\,{}_2F_1(1-a,\ c-a;\ b+1-a;\ z^{-1}) \quad (46) $$

$$ u_4^{(3)}(x) = (1-z)^{-b}\,{}_2F_1(b,\ c-a;\ b+1-a; (1-z)^{-1}) \quad (47) $$

$$ u_4^{(4)}(x) = (-z)^{1-c} \times (1-z)^{c-b-1}\,{}_2F_1(b+1-c,\ 1-a;\ b+1-a; (1-z)^{-1}) \quad (48) $$

$$u_5^{(1)}(x) = z^{1-c}\, {}_2F_1(a+1-c,\ b+1-c;\ 2-c;\ z) \quad (49)$$

$$u_5^{(2)} = z^{1-c}(1-z)^{c-a-b}\, {}_2F_1(1-a,\ 1-b;\ 2-c;\ z) \quad (50)$$

$$u_5^{(3)}(x) = z^{1-c}(1-z)^{c-a-1}\, {}_2F_1(a+1-c,\ 1-b;\ 2-c;\ z/(z-1)) \quad (51)$$

$$u_5^{(4)}(x) = z^{1-c}(1-z)^{c-b-1}\, {}_2F_1(b+1-c,\ 1-a;\ 2-c;\ z/(z-1)) \quad (52)$$

$$u_6^{(1)}(x) = (1-z)^{c-a-b}\, {}_2F_1(c-a,\ c-b;\ c+1-a-b;\ 1-z) \quad (53)$$

$$u_6^{(2)}(x) = z^{1-c}(1-z)^{c-a-b}\, {}_2F_1(1-a,\ 1-b;\ c+1-a-b;\ 1-z) \quad (54)$$

$$u_6^{(3)}(x) = z^{a-c}(1-z)^{c-a-b}\, {}_2F_1(c-a,\ 1-a;\ c+1-a-b;\ 1-z^{-1}) \quad (55)$$

$$u_6^{(4)}(x) = z^{b-c}(1-z)^{c-a-b}\, {}_2F_1(c-b,\ 1-b;\ c+1-a-b;\ 1-z^{-1}) \quad (56)$$

(Kummer 1836; Erdélyi *et al.* 1981, pp. 105–06).

Goursat (1881) and Erdélyi *et al.* (1981) give many hypergeometric transformation formulas, including several cubic transformations.

Many functions of mathematical physics can be expressed as special cases of the hypergeometric functions. For example,

$${}_2F_1(-l,\ l+1,\ 1;\ (1-z)/2) = P_l(z), \quad (57)$$

where $P_l(z)$ is a LEGENDRE POLYNOMIAL.

$$(1+z)^n = {}_2F_1(-n,\ b;\ b;\ -z) \quad (58)$$

$$\ln(1+z) = z\, {}_2F_1(1,\ 1;\ 2;\ -z) \quad (59)$$

Complete ELLIPTIC INTEGRALS and the RIEMANN P-SERIES can also be expressed in terms of ${}_2F_1(a,\ b;\ c;\ z)$. Special values include

$${}_2F_1(a,\ b;\ a-b+1;\ -1) = 2^{-a}\sqrt{\pi}\frac{\Gamma(1+a+b)}{\Gamma\left(1+\tfrac{1}{2}a-b\right)\Gamma\left(\tfrac{1}{2}+\tfrac{1}{2}a\right)} \quad (60)$$

$${}_2F_1(1,\ -a;\ a;\ -1) = \frac{\sqrt{\pi}}{2}\frac{\Gamma(a)}{\Gamma\left(a+\tfrac{1}{2}\right)} + 1 \quad (61)$$

$${}_2F_1\left(a,\ b;\ c;\ \tfrac{1}{2}\right) = 2^a\, {}_2F_1(a,\ c-b;\ c;\ -1) \quad (62)$$

$${}_2F_1\left(a,\ b;\ \tfrac{1}{2}(a+b+1);\ \tfrac{1}{2}\right) = \frac{\Gamma\left(\tfrac{1}{2}\right)\Gamma\left[\tfrac{1}{2}(1+a+b)\right]}{\Gamma\left[\tfrac{1}{2}(1+a)\right]\Gamma\left[\tfrac{1}{2}(1+b)\right]} \quad (63)$$

$${}_2F_1\left(a,\ 1-a;\ c;\ \tfrac{1}{2}\right) = \frac{\Gamma\left(\tfrac{1}{2}c\right)\Gamma\left[\tfrac{1}{2}(c+1)\right]}{\Gamma\left[\tfrac{1}{2}(a+c)\right]\Gamma\left[\tfrac{1}{2}(1+c-a)\right]} \quad (64)$$

$${}_2F_1(a,\ b;\ c;\ 1) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}. \quad (65)$$

KUMMER'S FIRST FORMULA gives

$${}_2F_1\left(\tfrac{1}{2}+m-k,\ -n;\ 2m+1;\ 1\right) = \frac{\Gamma(2m+1)\Gamma\left(m+\tfrac{1}{2}+k+n\right)}{\Gamma\left(m+\tfrac{1}{2}+k\right)\Gamma(2m+1+n)}, \quad (66)$$

where $m \neq -1/2,\ -1,\ -3/2,\ \ldots$. Many additional identities are given by Abramowitz and Stegun (1972, p. 557).

Hypergeometric functions can be generalized to GENERALIZED HYPERGEOMETRIC FUNCTIONS

$${}_nF_m(a_1,\ \ldots,\ a_n;\ b_1,\ \ldots,\ b_m;\ z). \quad (67)$$

A function OF THE FORM ${}_1F_1(a;\ b;\ z)$ is called a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND, and a function OF THE FORM ${}_0F_1(a;\ b;\ z)$ is called a CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION.

Hypergeometric Identity

A relation expressing a sum potentially involving BINOMIAL COEFFICIENTS, FACTORIALS, RATIONAL FUNCTIONS, and power functions in terms of a simple result. Thanks to results by Fasenmyer, Gosper, Zeilberger, Wilf, and Petkovsek, the problem of determining whether a given hypergeometric sum is expressible in simple closed form and, if so, finding the form, is now (subject to a mild restriction) completely solved. The algorithm which does so has been implemented in several computer algebra packages and is called ZEILBERGER'S ALGORITHM.

Hypergeometric Polynomial

JACOBI POLYNOMIAL

Hypergeometric Series

A hypergeometric series $\Sigma_k c_k$ is a series for which $c_0=1$ and the ratio of consecutive terms is a RATIONAL FUNCTION of the summation index k, i.e., one for which

$$\frac{c_{k+1}}{c_k}=\frac{P(k)}{Q(k)}, \tag{1}$$

with $P(k)$ and $Q(k)$ POLYNOMIALS. In this case, c_k is called a HYPERGEOMETRIC TERM (Koepf 1998, p. 12). The functions generated by hypergeometric series are called HYPERGEOMETRIC FUNCTIONS or, more generally, GENERALIZED HYPERGEOMETRIC FUNCTIONS. If the polynomials are completely factored, the ratio of successive terms can be written

$$\frac{c_{k+1}}{c_k}=\frac{P(k)}{Q(k)}=\frac{(k+a_1)(k+a_2)\cdots(k+a_p)}{(k+b_1)(k+b_2)\cdots(k+b_q)(k+1)}\,x, \tag{2}$$

where the factor of $k+1$ in the DENOMINATOR is present for historical reasons of notation, and the

resulting GENERALIZED HYPERGEOMETRIC FUNCTION is written

$$ {}_pF_q\begin{bmatrix} a_1 & a_2 & \cdots & a_p; \; x \\ b_1 & b_2 & \cdots & b_q \end{bmatrix} = \sum_{k=0} c_k x^k. \qquad (3)$$

If $p=2$ and $q=1$, the function becomes a traditional HYPERGEOMETRIC FUNCTION ${}_2F_1(a, b; c; x)$.

Many sums can be written as GENERALIZED HYPERGEOMETRIC FUNCTIONS by inspections of the ratios of consecutive terms in the generating hypergeometric series.

Hyperperfect Number

A number n is called k-hyperperfect if

$$n = 1 + k \sum_i d_i = 1 + k[\sigma(n) - n - 1],$$

where $\sigma(n)$ is the DIVISOR FUNCTION and the summation is over the PROPER DIVISORS with $1 < d_i < n$. Rearranging gives

$$k\sigma(n) = (k+1)n + k - 1.$$

Taking $k = 1$ gives the usual PERFECT NUMBERS.

If $k > 1$ is an odd integer, and $p = (3k+1)/2$ and $q = 3k + 4 = 2p + 3$ are prime, then $p^2 q$ is k-hyperperfect. McCranie (2000) conjectures that all k-hyperperfect numbers for odd $k > 1$ are in fact of this form. Similarly, if p and q are distinct odd primes such that $k(p+q) = pq - 1$ for some integer k, then $n = pq$ is k-hyperperfect. Finally, if $k > 0$ and $p = k + 1$ is prime, then if $q = p^i - p + 1$ is prime for some $i > 1 <$ then $n = p^{i-1} q$ is k-hyperperfect (McCranie 2000).

The first few hyperperfect numbers (excluding PERFECT NUMBERS) are 21, 301, 325, 697, 1333, ... (Sloane's A007592). If PERFECT NUMBERS are included, the first few are 6, 21, 28, 301, 325, 496, ... (Sloane's A034897), whose corresponding values of k are 1, 2, 1, 6, 3, 1, 12, ... (Sloane's A034898). The following table gives the first few k-hyperperfect numbers for small values of k. McCranie (2000) has tabulated all hyperperfect numbers less than 10^{11}.

k	Sloane	k-hyperperfect number
1	A000396	6 ,28, 496, 8128, ...
2	A007593	21, 2133, 19521, 176661, ...
3		325, ...
4		1950625, 1220640625, ...
6	A028499	301, 16513, 60110701, ...
10		159841, ...
11		10693, ...
12	A028500	697, 2041, 1570153, 62722153, ...

Hyperplane

Let a_1, a_2, ..., a_n be SCALARS not all equal to 0. Then the SET S consisting of all VECTORS

$$\mathbf{X} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}$$

in $\mathbb{R}^n$ such that

$$a_1 x_1 + a_2 x_2 + \ldots + a_n x_n = 0$$

is a SUBSPACE of $\mathbb{R}^n$ called a hyperplane.

More generally, a hyperplane is any CODIMENSION-1 vector SUBSPACE of a VECTOR SPACE. Equivalently, a hyperplane V in a VECTOR SPACE W is any SUBSPACE such that W/V is 1-dimensional. Equivalently, a hyperplane is the KERNEL of any NONZERO linear MAP from the VECTOR SPACE to the underlying FIELD.

Hyperreal Number

Hyperreal numbers are an extension of the REAL NUMBERS to include certain classes of infinite and infinitesimal numbers. A hyperreal number x is said to be finite IFF $|x| < n$ for some INTEGER n. x is said to be infinitesimal IFF $|x| < 1/n$ for all INTEGERS n.

Hyperspace

A SPACE having DIMENSION $n > 3$.

Hypersphere

The n-hypersphere (often simply called the n-sphere) is a generalization of the CIRCLE ($n = 2$) and SPHERE ($n = 3$) to dimensions $n \geq 4$. It is therefore defined as the set of n-tuples of points (x_1, x_2, ..., x_n) such that

$$x_1^2 + x_2^2 + \ldots + x_n^2 = R^2, \tag{1}$$

where R is the RADIUS of the hypersphere. The CONTENT V_n (i.e., n-D VOLUME) of an n-hypersphere of RADIUS R is given by

$$V_n = \int_0^R S_n r^{n-1}\, dr = \frac{S_n R^n}{n}, \tag{2}$$

where S_n is the hyper-SURFACE AREA of an n-sphere of unit radius. But, for a unit hypersphere, it must be true that

$$S_n \int_0^\infty e^{-r^2} r^{n-1}\, dr$$
$$= \underbrace{\int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty}}_{n} e^{-(x_1^2+\cdots+x_n^2)}\, dx_1 \cdots dx_m$$
$$= \left(\int_{-\infty}^{\infty} e^{-x^2}\, dx \right)^n. \tag{3}$$

But the GAMMA FUNCTION can be defined by

$$\Gamma(m) = 2 \int_0^\infty e^{-r^2} r^{2m-1}\, dr, \tag{4}$$

so

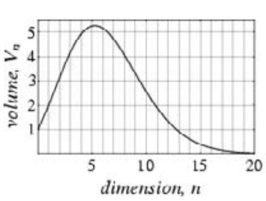
$$\tfrac{1}{2} S_n \Gamma\left(\tfrac{1}{2} n\right) = \left[\Gamma\left(\tfrac{1}{2}\right)\right]^n = (\pi^{1/2})^n \tag{5}$$

$$S_n = \frac{2\pi^{n/2}}{\Gamma\left(\frac{1}{2} n\right)}. \tag{6}$$

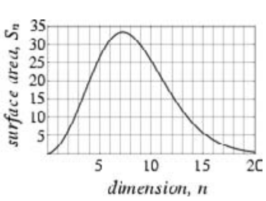
Special forms of $\Gamma\left(\frac{1}{2} n\right)$ for n an integer allow the above expression to be written as

$$S_n = \begin{cases} \dfrac{2^{(n+1)/2} \pi^{(n-1)/2}}{(n-2)!!} & \text{for } n \text{ odd} \\ \dfrac{2\pi^{n/2}}{\left(\frac{1}{2} n - 1\right)!} & \text{for } n \text{ even,} \end{cases} \tag{7}$$

where $n!$ is a FACTORIAL and $n!!$ is a DOUBLE FACTORIAL.



Equation (6) gives the RECURRENCE RELATION



$$S_{n+2} = \frac{2\pi S_n}{n}. \tag{8}$$

Using $\Gamma(n+1) = n\Gamma(n)$ then gives

$$V_n = \frac{S_n R^n}{n} = \frac{\pi^{n/2} R^n}{\left(\frac{1}{2} n\right) \Gamma\left(\frac{1}{2} n\right)} = \frac{\pi^{n/2} R^n}{\Gamma\left(1 + \frac{1}{2} n\right)} \tag{9}$$

(Sommerville 1958, p. 136; Conway and Sloane 1993).

Strangely enough, the hyper-SURFACE AREA and CONTENT reach MAXIMA and then decrease towards 0 as n increases. The point of MAXIMAL hyper-SURFACE AREA satisfies

$$\frac{dS_n}{dn} = \frac{\pi^{n/2}\left[\ln \pi - \psi_0\left(\frac{1}{2} n\right)\right]}{\Gamma\left(\frac{1}{2} n\right)} = 0, \tag{10}$$

where $\psi_0(x) \equiv \Psi(x)$ is the DIGAMMA FUNCTION. The point of MAXIMAL CONTENT satisfies

$$\frac{dV_n}{dn} = \frac{\pi^{n/2}\left[\ln \pi - \psi_0\left(1 + \frac{1}{2} n\right)\right]}{2\Gamma\left(1 + \frac{1}{2} n\right)} = 0. \tag{11}$$

Neither can be solved analytically for n, but the numerical solutions are $n = 7.25695\ldots$ for hyper-SURFACE AREA and $n = 5.25695\ldots$ for CONTENT (Wells 1986, p. 67). As a result, the 7-D and 5-D hyperspheres have MAXIMAL hyper-SURFACE AREA and CONTENT, respectively (Le Lionnais 1983; Wells 1986, p. 60).

n	V_n	$V_{\text{sphere}}/V_{\text{cube}}$	S_n
0	1	1	0
1	2	1	2
2	π	$\frac{1}{4}\pi$	2π
3	$\frac{4}{3}\pi$	$\frac{1}{6}\pi$	4π
4	$\frac{1}{2}\pi^2$	$\frac{1}{32}\pi^2$	$2\pi^2$
5	$\frac{8}{15}\pi^2$	$\frac{1}{60}\pi^2$	$\frac{8}{3}\pi^2$
6	$\frac{1}{6}\pi^3$	$\frac{1}{384}\pi^3$	π^3
7	$\frac{16}{105}\pi^3$	$\frac{1}{840}\pi^3$	$\frac{16}{15}\pi^3$
8	$\frac{1}{24}\pi^4$	$\frac{1}{6144}\pi^4$	$\frac{1}{3}\pi^4$
9	$\frac{32}{945}\pi^4$	$\frac{1}{15120}\pi^4$	$\frac{32}{105}\pi^4$
10	$\frac{1}{120}\pi^5$	$\frac{1}{122880}\pi^5$	$\frac{1}{12}\pi^5$

In 4-D, the generalization of SPHERICAL COORDINATES is defined by

$$x_1 = R \sin\psi \sin\phi \cos\theta \tag{12}$$

$$x_2 = R \sin\psi \sin\phi \sin\theta \tag{13}$$

$$x_3 = R \sin\psi \cos\phi \tag{14}$$

$$x_4 = R \cos\psi. \tag{15}$$

The equation for a 4-sphere is

$$x_1^2 + x_2^2 + x_3^2 + x_4^2 = R^2, \tag{16}$$

and the LINE ELEMENT is

$$ds^2 = R^2[d\psi^2 + \sin^2\psi(d\phi^2 + \sin^2\phi\, d\theta^2)]. \tag{17}$$

By defining $r \equiv R \sin\psi$, the LINE ELEMENT can be rewritten

$$ds^2 = \frac{dr^2}{\left(1 - \frac{r^2}{R^2}\right)} + r^2(d\phi^2 + \sin^2\phi\, d\theta^2). \tag{18}$$

The hyper-SURFACE AREA is therefore given by

$$S_4 = \int_0^\pi R\, d\psi \int_0^\pi R \sin\psi\, d\phi \int_0^{2\pi} R \sin\psi \sin\phi\, d\phi$$
$$= 2\pi^2 R^3. \tag{19}$$

Hypersphere Packing

The analog of face-centered cubic packing is the densest lattice packing in 4- and 5-D. In 8-D, the densest lattice packing is made up of two copies of face-centered cubic. In 6- and 7-D, the densest lattice packings are CROSS SECTIONS of the 8-D case. In 24-D, the densest packing appears to be the LEECH LATTICE. For high dimensions ($\sim$ 1000-D), the densest known packings are nonlattice. The densest lattice packings in n-D have been rigorously proved to have PACKING DENSITY 1, $\pi/(2\sqrt{3})$, $\pi/(3\sqrt{2})$, $\pi^2/16$, $\pi^2/(15\sqrt{2})$, $\pi^3/(48\sqrt{3})$, $\pi^3/105$, and $\pi^4/384$ (Hilbert and Cohn-Vossen 1999, p. 47; Finch).

The densest known *non-lattice* packings of hyperspheres in dimensions up to 10 are given by Conway and Sloane (1995). However, there are no proofs that any packing in dimensions greater than 3 is optimal (Sloane 1998).

hexagonal close packing of circles *hexagonal close packing of spheres* *cubic close packing of spheres*

The largest number of UNIT CIRCLES which can touch a given UNIT CIRCLE is six. For SPHERES, the maximum number is 12. Newton considered this question long before a proof was published in 1874. The maximum number of hyperspheres that can touch another in n-D is the so-called KISSING NUMBER.

The following example illustrates the sometimes counterintuitive properties of hypersphere packings. Draw unit n-spheres in an n-D space centered at all ± 1 coordinates. Now place an additional HYPERSPHERE at the origin tangent to the other HYPERSPHERES. For values of n between 2 and 8, the central HYPERSPHERE is contained inside the HYPERCUBE with VERTICES at the centers of the other spheres. However, for $n = 9$, the central HYPERSPHERE just touches the HYPERCUBE of centers, and for $n > 9$, the central HYPERSPHERE is partially *outside* the HYPERCUBE.

This fact can be demonstrated by finding the distance from the origin to the center of one of the n HYPERSPHERES, which is given by

$$\underbrace{\sqrt{(\pm 1)^2 + \ldots + (\pm 1)^2}}_{n} = \sqrt{n}.$$

The radius of the central sphere is therefore $\sqrt{n} - 1$. Now, the distance from the origin to the center of a FACET bounding the HYPERCUBE is always 2 (two hypersphere radii), so the center HYPERSPHERE is tangent to the hypercube when $\sqrt{n} - 1 = 2$, or $n = 9$, and partially outside it for $n > 9$.

Hypersphere Point Picking

Marsaglia (1972) has given a simple method for selecting points with a uniform distribution on the surface of a 4-sphere. This is accomplished by picking two pairs of points (x_1, x_2) and (x_3, x_4), rejecting any points for which $x_1^2 + x_2^2 \geq 1$ and $x_3^2 + x_4^2 \geq 1$. Then the points

$$x = x_1 \tag{1}$$

$$y = x_2 \tag{2}$$

$$z = x_3\sqrt{\frac{1 - x_1^2 - x_2^2}{x_2^3 + x_4^2}} \tag{3}$$

$$w = x_4 \sqrt{\frac{1 - x_1^2 - x_2^2}{x_2^3 + x_4^2}} \tag{4}$$

have a uniform distribution on the surface of the hypersphere. This extends the method of Marsaglia (1972) for SPHERE POINT PICKING.

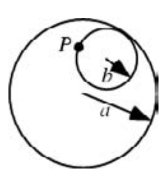
Hyperspherical Differential Equation

ULTRASPHERICAL DIFFERENTIAL EQUATION

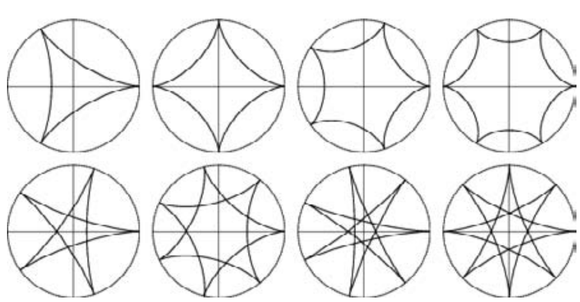
Hypersurface

A generalization of an ordinary two-dimensional surface embedded in three-dimensional space to an $(n-1)$-dimensional surface embedded in n-dimensional space. A hypersurface is therefore the set of solutions to a single equation

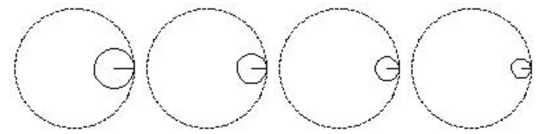
$$f(x_1, \ldots, x_n) = 0$$



and so it has CODIMENSION one. For instance, the n-dimension HYPERSPHERE $_n$ corresponds to the equation $x_1^2 + \ldots + x_n^2 = 1$.



See also HYPERSPHERE, SURFACE



Hypervolume

CONTENT

Hypocycloid

The curve produced by fixed point P on the CIRCUMFERENCE of a small CIRCLE of RADIUS b rolling around the inside of a large CIRCLE of RADIUS $a > b$. A hypocycloid is a HYPOTROCHOID with $h = b$. To derive the equations of the hypocycloid, call the ANGLE by which a point on the small CIRCLE rotates about its center ϑ, and the ANGLE from the center of the large CIRCLE to that of the small CIRCLE ϕ. Then

$$(a-b)\phi = b\vartheta, \tag{1}$$

so

$$\vartheta = \frac{a-b}{b}\,\phi. \tag{2}$$

Call $\rho \equiv a - 2b$. If $x(0) = \rho$, then the first point is at minimum radius, and the Cartesian parametric equations of the hypocycloid are

$$x = (a-b)\cos\phi - b\cos\vartheta$$

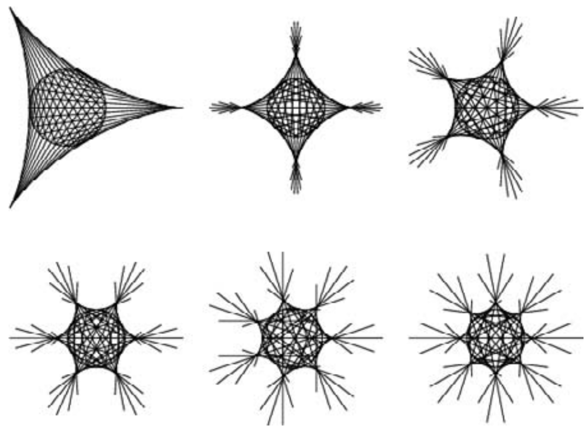
$$= (a-b)\cos\phi - b\cos\left(\frac{a-b}{b}\,\phi\right) \tag{3}$$

$$y = (a-b)\sin\phi - b\sin\vartheta$$

$$= (a-b)\sin\phi + b\sin\left(\frac{a-b}{b}\,\phi\right). \tag{4}$$

If $x(0) = a$ instead so the first point is at maximum radius (on the CIRCLE), then the equations of the hypocycloid are

$$x = (a-b)\cos\phi + b\cos\left(\frac{a-b}{b}\,\phi\right) \tag{5}$$



$$y = (a-b)\sin\phi - b\sin\left(\frac{a-b}{b}\,\phi\right). \tag{6}$$

An n-cusped non-self-intersecting hypocycloid has $a/b = n$. A 2-cusped hypocycloid is a LINE SEGMENT (Steinhaus 1983, p. 145), as can be seen by setting $a = b$ in equations (3) and (4) and noting that the equations simplify to

$$x = a\sin\phi \tag{7}$$

$$y = 0. \tag{8}$$

A 3-cusped hypocycloid is called a DELTOID or TRICUSPOID, and a 4-cusped hypocycloid is called an ASTROID. If a/b is rational, the curve closes on itself and has b cusps. If a/b is IRRATIONAL, the curve never closes and fills the entire interior of the CIRCLE.

n-hypocycloids can also be constructed by beginning with the DIAMETER of a CIRCLE, offsetting one end by a series of steps while at the same time offsetting the other end by steps n times as large in the opposite direction and extending beyond the edge of the CIRCLE. After traveling around the CIRCLE once, an n-cusped hypocycloid is produced, as illustrated above (Madachy 1979).

Let r be the radial distance from a fixed point. For RADIUS OF TORSION ρ and ARC LENGTH s, a hypocycloid can given by the equation

$$s^2 + \rho^2 = 16r^2 \tag{9}$$

(Kreyszig 1991, pp. 63–4). A hypocycloid also satisfies

$$\sin^2 \psi = \frac{\rho^2}{a^2 - \rho^2} \frac{a^2 - r^2}{r^2}, \tag{10}$$

where

$$r \frac{dr}{d\theta} = \tan \psi \tag{11}$$

and ψ is the ANGLE between the RADIUS VECTOR and the TANGENT to the curve.

The ARC LENGTH of the hypocycloid can be computed as follows

$$\begin{aligned} x' &= -(a-b)\sin \phi - (a-b)\sin\left(\frac{a-b}{b} \phi\right) \\ &= (a-b)\left[\sin \phi + \sin\left(\frac{a-b}{b} \phi\right)\right] \end{aligned} \tag{12}$$

$$\begin{aligned} y' &= (a-b)\cos \phi - (a-b)\cos\left(\frac{a-b}{a} \phi\right) \\ &= (a-b)\left[\cos \phi - \cos\left(\frac{a-b}{b} \phi\right)\right] \end{aligned} \tag{13}$$

$$\begin{aligned} x'^2 + y'^2 &= (a-b)^2\left[\sin^2 \phi + 2 \sin \phi \sin\left(\frac{a-b}{b} \phi\right)\right. \\ &+ \sin^2\left(\frac{a-b}{b} \phi\right) + \cos^2 \phi - 2 \cos \phi \cos\left(\frac{a-b}{b} \phi\right) \\ &\left. + \cos^2\left(\frac{a-b}{b} \phi\right)\right] \\ &= (a-b)^2\left\{2 + 2\left[\sin \phi \sin\left(\frac{a-b}{a} \phi\right)\right.\right. \\ &\left.\left. - \cos \phi \cos\left(\frac{a-b}{b} \phi\right)\right]\right\} \\ &= 2(a-b)^2\left[1 - \cos\left(\phi + \frac{a-b}{b} \phi\right)\right] \\ &= 4(a-b)^2 \tfrac{1}{2}\left[1 - \cos\left(\frac{a}{b} \phi\right)\right] \\ &= 4(a-b)^2 \sin^2\left(\frac{a\phi}{2b}\right), \end{aligned} \tag{14}$$

so

$$ds = \sqrt{x'^2 + y'^2}\, d\phi = 2(a-b)\sin\left(\frac{a\phi}{2b}\right) d\phi \tag{15}$$

for $\phi \leq (b/2a)\pi$. Integrating,

$$\begin{aligned} s(\phi) &= \int_0^\phi ds = 2(a-b)\left[-\frac{2b}{a} \cos\left(\frac{a\phi}{2b}\right)\right]_0^\phi \\ &= \frac{4b(a-b)}{a}\left[-\cos\left(\frac{a}{2b} \phi\right) + 1\right] \\ &= \frac{8b(a-b)}{a} \sin^2\left(\frac{a}{4b} \phi\right). \end{aligned} \tag{16}$$

The length of a single cusp is then

$$s\left(2\pi \frac{b}{a}\right) = \frac{8b(a-b)}{a} \sin^2\left(\frac{\pi}{2}\right) = \frac{8b(a-b)}{a}. \tag{17}$$

If $n \equiv a/b$ is rational, then the curve closes on itself without intersecting after n cusps. For $n \equiv a/b$ and with $x(0) = a$, the equations of the hypocycloid become

$$x = \frac{1}{n}[(n-1)\cos \phi - \cos[(n-1)\phi]\, a, \tag{18}$$

$$y = \frac{1}{n}[(n-1)\sin \phi + \sin[(n-1)\phi]\, a, \tag{19}$$

and

$$s_n = n\,\frac{8b(bn-b)}{nb} = 8b(n-1) = \frac{8a(n-1)}{n}. \qquad (20)$$

Compute

$$\begin{aligned} xy' - yx' &= \left[(a-b)\cos\phi + b\cos\left(\frac{a-b}{a}\,\phi\right)\right](b-a) \\ &\quad\times\left[\sin\phi + \sin\left(\frac{a-b}{b}\,\phi\right)\right] \\ &\quad-\left[(a-b)\sin\phi - b\sin\left(\frac{a-b}{b}\,\phi\right)\right](a-b) \\ &\quad\times\left[\cos\phi - \cos\left(\frac{a-b}{b}\,\phi\right)\right] \\ &= 2(a^2-3ab+2b^2)\sin^2\left(\frac{a\phi}{2b}\right). \qquad (21)\end{aligned}$$

The AREA of one cusp is then

$$\begin{aligned} A &= \tfrac{1}{2}\int_0^{2\pi b/a}(xy'-yx')\,d\phi \\ &= (a^2-3ab+2b^2)\left[\frac{at - b\sin\left(\frac{at}{b}\right)}{2a}\right]_a^{2\pi b/a} \\ &= (a^2-3ab+2b^2)\left[\frac{a\left(2\pi\frac{b}{a}\right)}{2a}\right] \\ &= \frac{b(a^2-3ab+2b^2)}{a}\,\pi. \qquad (22)\end{aligned}$$

If $n = a/b$ is rational, then after n cusps,

$$\begin{aligned} A_n &= n\pi\,\frac{b(a^2-3ab+2b^2)}{a} \\ &= n\pi\,\frac{\frac{a}{n}\left(a^2 - 3a\frac{a}{n} + 2\,\frac{a^2}{n^2}\right)}{a} \\ &= \frac{n^2-3n+2}{n^2}\,\pi a^2 = \frac{(n-1)(n-2)}{n^2}\,\pi a^2. \qquad (23)\end{aligned}$$

The equation of the hypocycloid can be put in a form which is useful in the solution of CALCULUS OF VARIATIONS problems with radial symmetry. Consider the case $x(0) = \rho$, then

$$r^2 = x^2 + y^2$$

$$\begin{aligned} &= \left[(a-b)^2\cos^2\phi - 2(a-b)b\cos\phi\cos\left(\frac{a-b}{b}\,\phi\right)\right. \\ &\quad +b^2\cos^2\left(\frac{a-b}{b}\,\phi\right) + (a-b)^2\sin^2\phi \\ &\quad +2(a-b)b\sin\phi\sin\left(\frac{a-b}{b}\,\phi\right) \\ &\quad \left.+b^2\sin^2\left(\frac{a-b}{b}\,\phi\right)\right] \\ &= \left\{(a-b)^2 + b^2 - 2(a-b)b\left[\cos\phi\cos\left(\frac{a-b}{b}\,\phi\right)\right.\right. \\ &\quad \left.\left.-\sin\phi\sin\left(\frac{a-b}{b}\,\phi\right)\right]\right\} \\ &= (a-b)^2 + b^2 - 2(a-b)b\cos\left(\frac{a}{b}\,\phi\right). \qquad (24)\end{aligned}$$

But $\rho = a - 2b$, so $b = (a-\rho)/2$, which gives

$$\begin{aligned} (a-b)^2 + b^2 &= \left[a - \tfrac{1}{2}(a-\rho)\right]^2 + \left[\tfrac{1}{2}(a-\rho)\right]^2 \\ &= \left[\tfrac{1}{2}(a+\rho)\right]^2 + \left[\tfrac{1}{2}(a-\rho)\right]^2 \\ &= \tfrac{1}{4}(a^2 + 2a\rho + \rho^2 + a^2 - 2a\rho + \rho^2) \\ &= \tfrac{1}{2}(a^2+\rho^2) \qquad (25)\end{aligned}$$

$$\begin{aligned} 2(a-b)b &= 2\left[a - \tfrac{1}{2}(a-\rho)\right]\tfrac{1}{2}(a-\rho) \\ &= \tfrac{1}{2}(a+\rho)(a-\rho) = \tfrac{1}{2}(a^2-\rho^2). \qquad (26)\end{aligned}$$

Now let

$$2\Omega t \equiv \frac{a}{b}\,\phi, \qquad (27)$$

so

$$\phi = \frac{a-\rho}{a}\,\Omega t \qquad (28)$$

$$\frac{\phi}{a-\rho} = \frac{\Omega t}{a}, \qquad (29)$$

then

$$\begin{aligned} r^2 &= \tfrac{1}{2}(a^2+\rho^2) - \tfrac{1}{2}(a^2-\rho^2)\cos\left(\frac{a}{b}\,\phi\right) \\ &= \tfrac{1}{2}(a^2+\rho^2) - \tfrac{1}{2}(a^2-\rho^2)\cos(2\Omega t). \qquad (30)\end{aligned}$$

The POLAR ANGLE is

$$\tan\theta \equiv \frac{y}{x} = \frac{(a-b)\sin\phi + b\sin\left(\frac{a-b}{a}\,\phi\right)}{(a-b)\cos\phi + b\cos\left(\frac{a-b}{a}\,\phi\right)}. \qquad (31)$$

But

$$b = \tfrac{1}{2}(a - \rho) \tag{32}$$

$$a - b = \tfrac{1}{2}(a + \rho) \tag{33}$$

$$\frac{a - b}{b} = \frac{a + \rho}{a - \rho}, \tag{34}$$

so

$$\tan\theta = \frac{\tfrac{1}{2}(a + \rho)\sin\phi + \tfrac{1}{2}(a - \rho)\sin\left(\frac{a+\rho}{z-\rho}\phi\right)}{\tfrac{1}{2}(a + \rho)\cos\phi - \tfrac{1}{2}(a - \rho)\cos\left(\frac{a+\rho}{a-\rho}\phi\right)}$$

$$= \frac{(a + \rho)\sin\left(\frac{a-\rho}{a}\Omega t\right) + (a - \rho)\sin\left(\frac{a+\rho}{a}\Omega t\right)}{(a + \rho)\cos\left(\frac{a-\rho}{a}\Omega t\right) - (a - \rho)\cos\left(\frac{a+\rho}{a}\Omega t\right)}$$

$$= \frac{a\left[\sin\left(\frac{a-\rho}{a}\Omega t\right) + \sin\left(\frac{a+\rho}{a}\Omega t\right)\right] + \rho\left[\sin\left(\frac{a-\rho}{a}\Omega t\right) - \sin\left(\frac{a+\rho}{a}\Omega t\right)\right]}{a\left[\cos\left(\frac{a-\rho}{a}\Omega t\right) - \cos\left(\frac{a+\rho}{a}\Omega t\right)\right] + \rho\left[\cos\left(\frac{a-\rho}{a}\Omega t\right) + \cos\left(\frac{a+\rho}{a}\Omega t\right)\right]}$$

$$= \frac{2a\sin(\Omega t)\cos\left(\frac{\rho}{q}\Omega t\right) - 2\rho\cos(\Omega t)\sin\left(\frac{\rho}{a}\Omega t\right)}{2a\sin(\Omega t)\sin\left(\frac{\rho}{q}\Omega t\right) + 2\rho\cos(\Omega t)\sin\left(\frac{\rho}{a}\Omega t\right)}$$

$$= \frac{a\tan(\Omega t) - \rho\tan\left(\frac{\rho}{a}\Omega t\right)}{a\tan(\Omega t)\tan\left(\frac{\rho}{a}\Omega t\right) + \rho}. \tag{35}$$

Computing

$$\tan\left(\theta + \frac{\rho}{a}\Omega t\right)$$

$$= \frac{\left[a\tan(\Omega t) - \rho\tan\left(\frac{\rho}{a}\Omega t\right) + \tan\left(\frac{\rho}{a}\Omega t\right)\right]\left[a\tan(\Omega t)\tan\left(\frac{\rho}{a}\Omega t\right) + \rho\right]}{\left[a\tan(\Omega t)\tan\left(\frac{\rho}{a}\Omega t\right) + \rho\right] - \left[a\tan(\Omega t) - \rho\tan\left(\frac{\rho}{a}\Omega t\right)\right]\tan\left(\frac{\rho}{a}\Omega t\right)}$$

$$= \frac{a\tan(\Omega t)\left[1 + \tan^2\left(\frac{\rho}{a}\Omega t\right)\right]}{\rho\left[1 + \tan^2\left(\frac{\rho}{a}\Omega t\right)\right]}$$

$$= \frac{a}{\rho}\tan(\Omega t), \tag{36}$$

then gives

$$\theta = \tan^{-1}\left[\frac{a}{\rho}\tan(\Omega t)\right] - \frac{\rho}{a}\Omega t. \tag{37}$$

Finally, plugging back in gives

$$\theta = \tan^{-1}\left[\frac{a}{\rho}\tan\left(\frac{a}{a - \rho}\phi\right)\right] - \frac{\rho}{a}\frac{a}{a - \rho}\phi$$

$$= \tan^{-1}\left[\frac{a}{\rho}\tan\left(\frac{a}{a - \rho}\phi\right)\right] - \frac{\rho}{a - \rho}\phi \tag{38}$$

This form is useful in the solution of the SPHERE WITH TUNNEL problem, which is the generalization of the BRACHISTOCHRONE PROBLEM, to find the shape of a tunnel drilled through a SPHERE (with gravity varying according to Gauss's law in a gravitational field such that the travel time between two points on the surface of the SPHERE under the force of gravity is minimized.

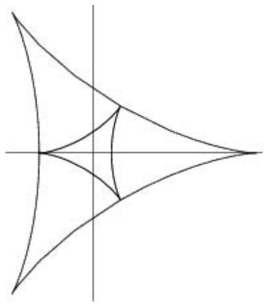
Hypocycloid Evolute

For $x(0) = a$,

$$x = \frac{a}{a - 2b}\left[(a - b)\cos\phi - b\cos\left(\frac{a - b}{b}\phi\right)\right]$$

$$y = \frac{a}{a - 2b}\left[(a - b)\sin\phi + b\sin\left(\frac{a - b}{b}\phi\right)\right].$$



If $a/b = n$, then

$$x = \frac{1}{n - 2}[(n - 1)\cos\phi - \cos[(n - 1)\phi]a$$

$$y = \frac{1}{n - 2}[(n - 1)\sin\phi - \sin[(n - 1)\phi]a.$$

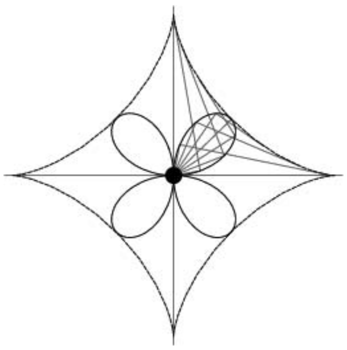
This is just the original HYPOCYCLOID scaled by the factor $(n-2)/n$ and rotated by $1/(2n)$ of a turn.

Hypocycloid Involute

The HYPOCYCLOID

$$x = \frac{a}{a-2b}\left[(a-b)\cos\phi - b\cos\left(\frac{a-b}{b}\phi\right)\right]$$

$$y = \frac{a}{a-2b}\left[(a-b)\sin\phi + b\sin\left(\frac{a-b}{b}\phi\right)\right]$$



has INVOLUTE

$$x = \frac{a-2b}{a}\left[(a-b)\cos\phi + b\cos\left(\frac{a-b}{b}\phi\right)\right]$$

$$y = \frac{a-2b}{a}\left[(a-b)\sin\phi - b\sin\left(\frac{a-b}{b}\phi\right)\right],$$

which is another HYPOCYCLOID.

Hypocycloid Pedal Curve

The PEDAL CURVE for a PEDAL POINT at the center is a ROSE.

Hypohamiltonian Graph

A graph G is hypohamiltonian if G is not HAMILTONIAN, but $G-v$ is HAMILTONIAN for every $v \in V$ (Bondy and Murty 1976, p. 61). The PETERSEN GRAPH, which has ten nodes and is illustrated above, is the smallest hypohamiltonian graph (Herz *et al.* 1967; Bondy and Murty 1976, p. 61). There are no hypohamiltonian graphs with 11 or 12 vertices. However, there exists a hypohamiltonian graph on p vertices for every $p \geq 13$ with the possible exceptions of $p = 14$, 17, 19. Thomassen (1973) found hypohamiltonian graphs on $p = 20$ and 25 vertices, which had previously been open.

A graph can be tested to see if it is hypohamiltonian using the following *Mathematica* function.

```
< <DiscreteMath`Combinatorica`;
HypohamiltonianQ[g_Graph]        :=        !
HamiltonianQ[g] &&    HamiltonianQ /@ And @@
(DeleteVertex[g, #] & /@ Range[V[g]])
```

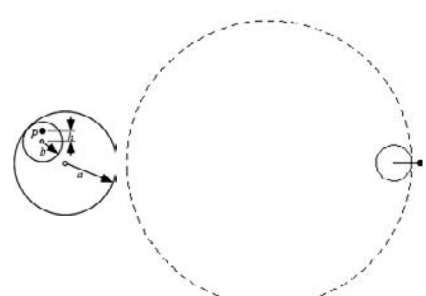
Hypotraceable Graph

G is a hypotraceable graph if G has no HAMILTONIAN PATH (i.e., it is not a TRACEABLE GRAPH), but $G-v$ has a HAMILTONIAN PATH (i.e., is a TRACEABLE GRAPH) for every $v \in V$ (Bondy and Murty 1976, p. 61).

T. Gallai conjectured that there exist no hypotraceable graphs (there are none on seven or fewer nodes), but the THOMASSEN GRAPH, illustrated above, provides a counterexample (Bondy and Murty 1973, pp. 239–40). However, a hypotraceable graph with 40 vertices was found by Horton (Grünbaum 1973, Thomassen 1974). Thomassen (1974) showed that for $p=34$, 37, 39, 40, and all $p \geq 42$, there exists a hypotraceable graph with p vertices. The smallest of these, the so-called THOMASSEN GRAPH, is illustrated above.



Walter (1969) gave an example of a connected graph in which the longest paths do not have a vertex in common, a property shared by hypotraceable graphs.

Hypotrochoid

The ROULETTE traced by a point P attached to a CIRCLE of radius b rolling around the inside of a fixed CIRCLE of radius a, where P is a distance $h \leq b$ from the center of the interior circle. The PARAMETRIC EQUATIONS for a hypotrochoid are

$$x = (a+b)\cos t - h\cos\left(\frac{a+b}{b}t\right), \quad (1)$$

$$y = (a+b)\sin t - h\sin\left(\frac{a+b}{b}t\right), \quad (2)$$

Special cases include the HYPOCYCLOID with $h = b$, the ELLIPSE with $a = 2b$, and the ROSE with

$$a = \frac{2nh}{n+1} \quad (3)$$

$$b = \frac{(n-1)h}{n+1}. \quad (4)$$

Hypotrochoid Evolute

The EVOLUTE of the HYPOTROCHOID is illustrated above.

Hyzer's Illusion

FREEMISH CRATE

I

i

"The" IMAGINARY NUMBER i (also called the IMAGINARY UNIT) is defined as the SQUARE ROOT of -1, i.e., $i \equiv \sqrt{-1}$. Although there are two possible square roots of any number, the square roots of a negative number cannot be distinguished until one of the two is defined as the imaginary unit, at which point $+i$ and $-i$ can then be distinguished. Since either choice is possible, there is no ambiguity in defining i as "the" square root of -1.

In *Mathematica*, the imaginary number is implemented as I. For some reason engineers and physicists prefer the symbol J to i, probably because the symbol i (or I) is commonly used to denote current.

Numbers OF THE FORM iy, where y is a REAL NUMBER, are called IMAGINARY NUMBERS. Numbers OF THE FORM $z = x + iy$ where x and y are REAL NUMBERS are called COMPLEX NUMBERS, and when z is used to denote a COMPLEX NUMBER, it is sometimes (in older texts) called an "AFFIX."

The SQUARE ROOT of i is

$$\sqrt{i} = \pm\frac{i+1}{\sqrt{2}}, \tag{1}$$

since

$$\left[\frac{1}{\sqrt{2}}(i+1)\right]^2 = \tfrac{1}{2}(i^2 + 2i + 1) = i. \tag{2}$$

This can be immediately derived from the EULER FORMULA with $x = \pi/2$,

$$i = e^{i\pi/2} \tag{3}$$

$$\sqrt{i} = \sqrt{e^{i\pi/2}} = e^{i\pi/4} = \cos\left(\tfrac{1}{4}\pi\right) + i\,\sin\left(\tfrac{1}{4}\pi\right) = \frac{1+i}{\sqrt{2}}. \tag{4}$$

The PRINCIPAL VALUE of i^i is

$$i^i = \left(e^{i\pi/2}\right)^i = e^{i^2\pi/2} = e^{-\pi/2} = 0.207879\ldots \tag{5}$$

(Wells 1986, p. 26).

Icosahedral Equation

Hunt (1996) gives the "dehomogenized" icosahedral equation as

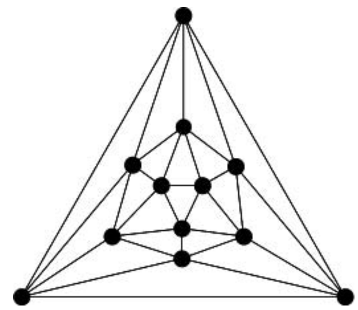
$$\left[(z^{20}+1)-228(z^{15}-z^5)+494z^{10}\right)^3$$
$$+1728uz^5(z^{10}+11z^5-1)^5 = 0.$$

Other forms include

$$I(u,v,Z) = u^5v^5(u^{10}+11u^5v^5-v^{10})^5$$
$$-[u^{30}+v^{30}-10005(u^{20}v^{10}+u^{10}v^{20})$$
$$+522(u^2 5v^5-u^5v^2 5)]^2 Z = 0$$

and

$$I(z,\,1,\,z) = z^5(-1+11z^5+z^{10})^5$$



$$-[1+z^{30}-10005(z^{10}+z^{20})+522(-z^5+z^{25})]^2 z = 0.$$

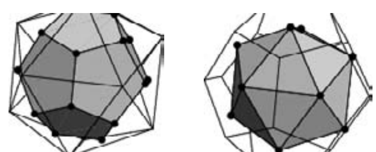
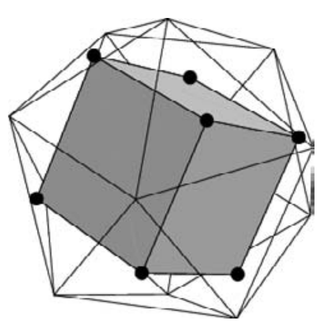
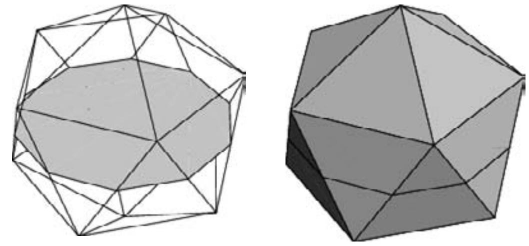
Lomont, J. S. "Icosahedral Group." §3.10.E in *Applications of Finite Groups.* New York: Dover, p. 82, 1987.

Icosahedron





A PLATONIC SOLID P_5 having 12 VERTICES, 30 EDGES, and 20 equivalent EQUILATERAL TRIANGLE faces, $20\{3\}$. It is also UNIFORM POLYHEDRON U_{22} and Wenninger model W_4. It is described by the SCHLÄFLI SYMBOL $\{3, 5\}$ and WYTHOFF SYMBOL $5|23$.



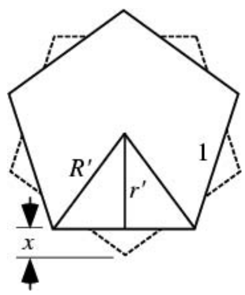
The icosahedron has the ICOSAHEDRAL GROUP I_h of symmetries. The connectivity of the vertices is given by the ICOSAHEDRAL GRAPH.

The DUAL POLYHEDRON of the icosahedron is the DODECAHEDRON, so the centers of the faces of an icosahedron form a DODECAHEDRON, and vice versa (Steinhaus 1983, pp. 199–01). There are 59 distinct icosahedra when each TRIANGLE is colored differently (Coxeter 1969).

Taken eight at a time, the centers of the faces of an icosahedron comprise the vertices of a CUBE. This leads to the beautiful CUBE 5-COMPOUND and is the basis for JESSEN'S ORTHOGONAL ICOSAHEDRON.

A plane PERPENDICULAR to a C_5 axis of an icosahedron cuts the solid in a regular DECAGONAL CROSS SECTION (Holden 1991, pp. 24–5).

The long diagonals of the faces of the RHOMBIC TRIACONTAHEDRON give the edges of an icosahedron (Steinhaus 1983, pp. 209–10).



The following table gives polyhedra which can be constructed by CUMULATION of an icosahedron by pyramids of given heights h.

h	$(r+h)/h$	Result
$\frac{1}{6}\sqrt{3}(\sqrt{5}-3)$	$3(\sqrt{5}-2)$	GREAT DODECAHEDRON
$\frac{1}{15}\sqrt{15}$	$\frac{1}{5}(10-3\sqrt{5})$	SMALL TRIAMBIC ICOSAHEDRON
$\frac{1}{3}\sqrt{6}$	$1-3\sqrt{2}+\sqrt{10}$	60-faced star DELTAHEDRON
$\frac{1}{6}\sqrt{3}(3+\sqrt{5})$	3	GREAT STELLATED DODECAHEDRON

A construction for an icosahedron with side length $a = \sqrt{50-10\sqrt{5}}/5$ places the end vertices at $(0, 0, \pm 1)$ and the central vertices around two staggered CIRCLES of RADII $\frac{2}{5}\sqrt{5}$ and heights $\pm\frac{1}{5}\sqrt{5}$. By a suitable rotation, the VERTICES of an icosahedron of side length 2 can also be placed at $(0, \pm\phi, \pm 1)$, $(\pm 1, 0, \pm\phi)$, and $(\pm\phi, \pm 1, 0)$, where ϕ is the GOLDEN RATIO. These points divide the EDGES of an OCTAHEDRON into segments with lengths in the ratio $\phi : 1$. Another orientation of the icosahedron places two opposite triangular faces in an orientation parallel to the xy-plane. In this orientation, the distance h' from the top

plane to the triangle T of vertices below it is $h' = \sqrt{3}/3$, equal to the circumradius of a face. The circumradius R_T of T is given by

$$R_T = \sqrt{\tfrac{1}{6}(3+\sqrt{5})}. \tag{1}$$

To derive the VOLUME of an icosahedron having edge length a, consider the orientation so that two VERTICES are oriented on top and bottom. The vertical distance between the top and bottom PENTAGONAL DIPYRAMIDS is then given by

$$z = \sqrt{\ell^2 - x^2}, \tag{2}$$

where

$$\ell = \tfrac{1}{2}\sqrt{3}a \tag{3}$$

is the height of an ISOSCELES TRIANGLE, and the SAGITTA $x = R' - r'$ of the pentagon is

$$x = \tfrac{1}{2}a\tfrac{1}{10}\sqrt{25 - 10\sqrt{5}a}, \tag{4}$$

giving

$$x^2 = \tfrac{1}{20}\sqrt{5 - 2\sqrt{5}a^2}. \tag{5}$$

Plugging (3) and (5) into (2) gives

$$z = \tfrac{1}{10}\sqrt{50 + 10\sqrt{5}a}, \tag{6}$$

which is identical to the radius of a PENTAGON of side a. The CIRCUMRADIUS is then

$$R = h + \tfrac{1}{2}z, \tag{7}$$

where

$$h = \tfrac{1}{10}\sqrt{50 - 10\sqrt{5}a} \tag{8}$$

is the height of a PENTAGONAL DIPYRAMID. Therefore,

$$R^2 = (h + \tfrac{1}{2}z)^2 = \tfrac{1}{8}(5+\sqrt{5})a^2. \tag{9}$$

Taking the square root gives the CIRCUMRADIUS

$$R = \sqrt{\tfrac{1}{8}(5+\sqrt{5})}a = \tfrac{1}{4}\sqrt{10 + 2\sqrt{5}}a \approx 0.95105a. \tag{10}$$

The INRADIUS is

$$r = \tfrac{1}{12}(3\sqrt{3} + \sqrt{15})a \approx 0.75576a. \tag{11}$$

The square of the MIDRADIUS is

$$\rho^2 = \left(\tfrac{1}{2}z\right)^2 + x_1^2 = \tfrac{1}{8}(3+\sqrt{5})a^2, \tag{12}$$

so

$$\rho = \sqrt{\tfrac{1}{8}(3+\sqrt{5})}a = \tfrac{1}{4}(1+\sqrt{5})a \approx 0.80901a. \tag{13}$$

The DIHEDRAL ANGLE is

$$a = \cos^{-1}(-\tfrac{1}{3}\sqrt{5}) \approx 138.19^\circ. \tag{14}$$

The AREA of one face is the AREA of an EQUILATERAL TRIANGLE

$$A = \tfrac{1}{4}a^2\sqrt{3}. \tag{15}$$

The volume can be computed by taking 20 pyramids of height r

$$V = 20\left[\left(\tfrac{1}{3}A\right)r\right] = \tfrac{5}{12}(3+\sqrt{5})a^3. \tag{16}$$

Apollonius showed that

$$\frac{V_{\text{icosahedron}}}{V_{\text{dodecahedron}}} = \frac{A_{\text{icosahedron}}}{A_{\text{dodecahedron}}}, \tag{17}$$

where V is the volume and A the SURFACE AREA.

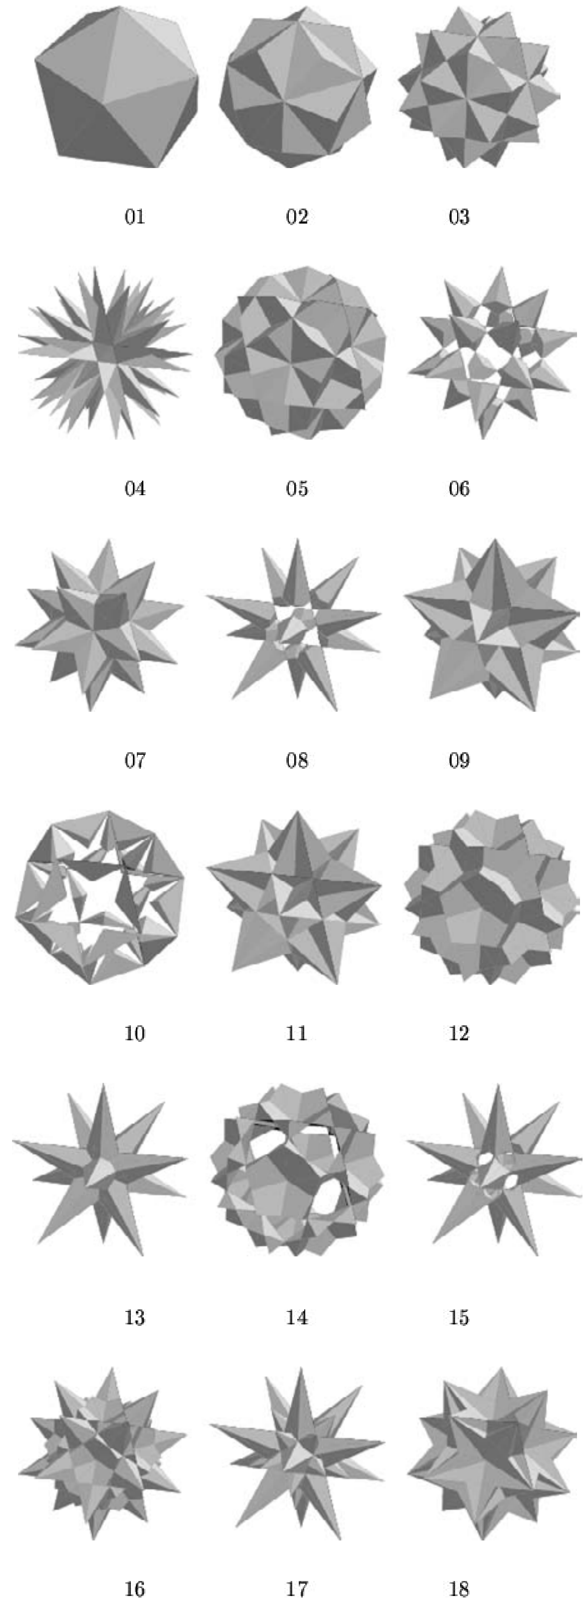
Icosahedron Stellations

Applying the STELLATION process to the ICOSAHEDRON gives



$$20+30+60+20+60+120+12+30+60+60$$

cells of ten different shapes and sizes in addition to the ICOSAHEDRON itself. After application of five restrictions due to J. C. P. Miller to define which forms should be considered distinct, 59 stellations are found to be possible. Miller's restrictions are

1. The faces must lie in the twenty bounding planes of the icosahedron.
2. The parts of the faces in the twenty planes must be congruent, but those parts lying in one place may be disconnected.
3. The parts lying in one plane must have threefold rotational symmetry with or without reflections.
4. All parts must be accessible, i.e., lie on the outside of the solid.
5. Compounds are excluded that can be divided into two sets, each of which has the full symmetry of the whole.

Of these, 32 have full icosahedral symmetry and 27 are ENANTIOMERIC forms. Four are POLYHEDRON COMPOUNDS, one is a KEPLER-POINSOT SOLID, and one is the DUAL POLYHEDRON of an ARCHIMEDEAN SOLID.

Icosian Game

The problem of finding a HAMILTONIAN CIRCUIT along the edges of an DODECAHEDRON, i.e., a path such that every vertex is visited a single time, no edge is visited twice, and the ending point is the same as the starting point (left figure). The puzzle was distributed commercially as a pegboard with holes at the nodes of the DODECAHEDRAL GRAPH, illustrated above (right figure). The Icosian Game was invented in 1857 by William Rowan Hamilton. Hamilton sold it to a London game dealer in 1859 for 25 pounds, and the game was subsequently marketed in Europe in a number of forms (Gardner 1957).

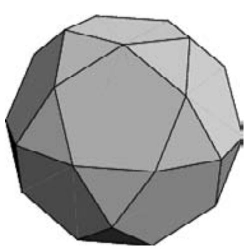
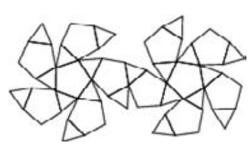
Wenninger, M. J. *Polyhedron Models.* Cambridge, England: Cambridge University Press, pp. 128–29, 1989.

Icosidodecagon

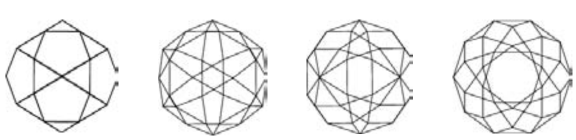
A 32-sided polygon. The regular icosidodecagon is a CONSTRUCTIBLE POLYGON, and the regular icosidodecahedron of side length 1 has INRADIUS r, CIRCUMRADIUS R, and AREA A



$$r=\frac{1}{2}\left[1+\sqrt{2}+\sqrt{2(2+\sqrt{2})}+\sqrt{2(2+\sqrt{2})\left(2+\sqrt{2+\sqrt{2}}\right)}\right]$$



$$R=\sqrt{\frac{1}{2}(2+\sqrt{2})\left(2+\sqrt{2+\sqrt{2}}\right)\left(2+\sqrt{2+\sqrt{2+\sqrt{2}}}\right)}$$



$$A=8\left[1+\sqrt{2}+\sqrt{2(2+\sqrt{2})}+\sqrt{2(2+\sqrt{2})\left(2+\sqrt{2+\sqrt{2}}\right)}\right].$$

See also TRIGONOMETRY VALUES PI/32

Icosidodecahedron

An icosidodecahedron is a 32-faced POLYHEDRON.

"The" icosidodecahedron is the 32-faced ARCHIMEDEAN SOLID A_4 with faces $20\{3\}+12\{5\}$. It is one of the two convex QUASIREGULAR POLYHEDRA. It also UNIFORM POLYHEDRON U_{24} and Wenninger model W_{12}. It has SCHLÄFLI SYMBOL $\left\{{3 \atop 5}\right\}$ and WYTHOFF SYMBOL 2|35.

The DUAL POLYHEDRON is the RHOMBIC TRIACONTAHEDRON. The VERTICES of an icosidodecahedron of EDGE length $2\phi^{-1}$ are $(\pm 2, 0, 0)$, $(0, \pm 2, 0)$, $(0, 0, \pm 2)$, $(\pm 1, \pm\phi^{-1}, \pm 1)$, $(\pm 1, \pm\phi, \pm\phi^{-1})$, $(\pm\phi^{-1}, \pm 1, \pm\phi)$. The 30 VERTICES of an OCTAHEDRON 5-COMPOUND form an icosidodecahedron (Ball and Coxeter 1987). FACETED versions include the SMALL ICOSIHEMIDODECAHEDRON and SMALL DODECAHEMIDODECAHEDRON.

The faces of the icosidodecahedron consist of 20 triangles and 12 pentagons. Furthermore, its 60 edges are bisected perpendicularly by those of the reciprocal RHOMBIC TRIACONTAHEDRON (Ball and Coxeter 1987).

The INRADIUS r of the dual, MIDRADIUS ρ of the solid and dual, and CIRCUMRADIUS R of the solid for $a=1$ are

$$r=\frac{1}{8}(5+3\sqrt{5})\approx 1.46353$$

$$\rho=\frac{1}{2}\sqrt{5+2\sqrt{5}}\approx 1.53884$$

$$R=\frac{1}{2}(1+\sqrt{5})=\phi\approx 1.61803.$$

The SURFACE AREA and VOLUME for an icosidodecahedron are given by

$$S=5\sqrt{3}+3\sqrt{5}\sqrt{5+2\sqrt{5}} \tag{1}$$

$$V=\frac{1}{6}45+17\sqrt{5} \tag{2}$$

The distance to the centers of the triangular and pentagonal faces are

$$r_3=\sqrt{\frac{1}{6}\left(7+3\sqrt{5}\right)} \tag{3}$$

$$r_5=\sqrt{\frac{1}{5}\left(5+2\sqrt{5}\right)}. \tag{4}$$

Ideal

A subset $\mathfrak{I}$ of elements in a RING R which forms an additive GROUP and has the property that, whenever x belongs to R and y belongs to $\mathfrak{I}$, then xy and yx belong to $\mathfrak{I}$. For example, the set of EVEN INTEGERS is an ideal in the RING of INTEGERS $\mathbb{Z}$. Given an ideal $\mathfrak{I}$, it is possible to define a FACTOR RING R/I. Ideals are commonly denoted using a Gothic typeface.

An ideal may be viewed as a lattice and specified as the finite list of algebraic integers that form a basis for the lattice. Any two bases for the same lattice are equivalent. Ideals have multiplication, and this is basically the KRONECKER PRODUCT of the two bases. From the perspective of ALGEBRAIC GEOMETRY, ideals correspond to VARIETIES.

For any ideal $\mathfrak{I}$, there is an ideal $\mathfrak{I}_i$ such that

$$\mathfrak{I}\mathfrak{I}_i=\mathfrak{z}, \tag{1}$$

where $\mathfrak{z}$ is a PRINCIPAL IDEAL, (i.e., an ideal of rank 1). Moreover there is a finite list of ideals $\mathfrak{I}_i$ such that this equation may be satisfied for every $\mathfrak{I}$. The size of this list is known as the CLASS NUMBER. In effect, the above relation imposes an EQUIVALENCE RELATION on ideals, and the number of ideals modulo this relation is the CLASS NUMBER. When the CLASS NUMBER is 1, the corresponding number RING has unique factorization and, in a sense, the class number is a measure of the failure of unique factorization in the original number ring.

Dedekind (1871) showed that every NONZERO ideal in the domain of INTEGERS of a FIELD is a unique product of PRIME IDEALS, and in fact all ideals of $\mathbb{Z}$ are of this form and therefore PRINCIPAL IDEALS.

Ideals can be added, multiplied and intersected. The union of ideals usually is not an ideal since it may not be closed under addition. From the perspective of ALGEBRAIC GEOMETRY, the addition of ideals corresponds to the intersection of VARIETIES and the intersection of ideals corresponds to the union of varieties. Also, the multiplication of ideals corresponds to the union of varieties.

Intersection and multiplication are different, for instance consider the ideal $\mathfrak{a}=(x)$ in $\mathbb{Z}[x,y]$. Then

$$\mathfrak{a}^2=\mathfrak{a}\cdot\mathfrak{a}=\langle x^2\rangle. \tag{2}$$

Sometimes they are the same. If $\mathfrak{b}=\langle y\rangle$, then

$$\mathfrak{ab}=\mathfrak{a}\cap\mathfrak{b}=\langle xy\rangle. \tag{3}$$

There is also an analog of division, the IDEAL QUOTIENT $(\mathfrak{a}:\mathfrak{b})$, and there is an analog of the RADICAL, also called the RADICAL $r(\mathfrak{a})$. Given a ring homomorphism $f:A\to B$, ideals in A EXTEND to ideals in B, while ideals in B CONTRACT to ideals in A.

The following formulas summarize operations on ideals, where $\mathfrak{r}^c$ denotes CONTRACT, $\mathfrak{r}^e$ denotes EXTENSION, and $(\mathfrak{a}:\mathfrak{b})$ denotes an IDEAL QUOTIENT.

$$\mathfrak{a}(\mathfrak{b}+\mathfrak{c})=\mathfrak{ab}+\mathfrak{ac} \tag{4}$$

$$(\mathfrak{a}:\mathfrak{b})\mathfrak{b}\subset\mathfrak{a} \tag{5}$$

$$(\cap\,\mathfrak{a}_i:\mathfrak{b})=\cap\,(\mathfrak{a}_i:\mathfrak{b}) \tag{6}$$

$$(\mathfrak{a}:\sum\mathfrak{b}_i)=\cap\,(\mathfrak{a}:\mathfrak{b}_i) \tag{7}$$

$$\mathfrak{a}\subset r(\mathfrak{a}) \tag{8}$$

$$r(r(\mathfrak{a}))=r(\mathfrak{a}) \tag{9}$$

$$r(\mathfrak{ab})=r(\mathfrak{a}\cap\mathfrak{b})=r(\mathfrak{a})\cap r(\mathfrak{b}) \tag{10}$$

$$r(\mathfrak{a}+\mathfrak{b})=r(r(\mathfrak{a})+r(\mathfrak{b})) \tag{11}$$

$$\mathfrak{a}\subset\mathfrak{a}^{ec} \tag{12}$$

$$\mathfrak{b}^{ce}\subset\mathfrak{b} \tag{13}$$

$$\mathfrak{b}^c=\mathfrak{b}^{cec} \tag{14}$$

$$\mathfrak{a}^e=\mathfrak{a}^{ece} \tag{15}$$

$$(\mathfrak{a}_1+\mathfrak{a}_2)^e=\mathfrak{a}_1^e+\mathfrak{a}_2^e \tag{16}$$

$$\mathfrak{b}_1^c+\mathfrak{b}_2^c\subset(\mathfrak{b}_1+\mathfrak{b}_2)^c \tag{17}$$

$$(\mathfrak{a}_1\cap\mathfrak{a}_2)^e\subset\mathfrak{a}_1^e\cap\mathfrak{a}_2^e \tag{18}$$

$$\mathfrak{b}_1^c\cap\mathfrak{b}_2^c=(\mathfrak{b}_1\cap\mathfrak{b}_2)^c \tag{19}$$

$$\mathfrak{a}_1^e\mathfrak{a}_2^e=(\mathfrak{a}_1\mathfrak{a}_2)^e \tag{20}$$

$$\mathfrak{b}_1^c\mathfrak{b}_2^c\subset(\mathfrak{b}_1\mathfrak{b}_2)^c \tag{21}$$

$$(\mathfrak{a}_1:\mathfrak{a}_2)^e\subset(\mathfrak{a}_1^e:\mathfrak{a}_2^e) \tag{22}$$

$$(\mathfrak{b}_1:\mathfrak{b}_2)^c\subset(\mathfrak{b}_1^c:\mathfrak{b}_2^c) \tag{23}$$

$$r(\mathfrak{a})^e\subset r(\mathfrak{a}^e) \tag{24}$$

$$r(\mathfrak{b})^c = r(\mathfrak{b}^c) \quad (25)$$

Ideal (Partial Order)

An ideal I of a PARTIAL ORDER P is a subset of the elements of P which satisfy the property that if $y \in 1$ and $x < y$, then $x \in I$. For k disjoint chains in which the ith chain contains n_i elements, there are $(1+n_1)(1+n_2)\cdots(1+n_k)$ ideals. The number of ideals of a n-element FENCE POSET is the FIBONACCI NUMBER F_n.

Ideal Function

DISTRIBUTION (GENERALIZED FUNCTION)

Ideal Number

A type of number involving the ROOTS OF UNITY which was developed by Kummer while trying to solve FERMAT'S LAST THEOREM. Although factorization over the INTEGERS is unique (the FUNDAMENTAL THEOREM OF ALGEBRA), factorization is *not* unique over the COMPLEX NUMBERS. Over the ideal numbers, however, factorization in terms of the COMPLEX NUMBERS becomes unique. Ideal numbers were so powerful that they were generalized by Dedekind into the more abstract IDEALS in general RINGS which are a key part of modern abstract ALGEBRA.

Ideal Point

A type of POINT AT INFINITY in which parallel lines in the HYPERBOLIC PLANE intersect at infinity in one direction, while diverging from one another in the other.

See also HYPERPARALLEL

Ideal Quotient

The ideal quotient $(\mathfrak{a}:\mathfrak{b})$ is an analog of division for IDEALS in a COMMUTATIVE RING R,

$$(\mathfrak{a}:\mathfrak{b}) = \{x \in R : x\mathfrak{b} \subset \mathfrak{a}\}.$$

The ideal quotient is always another ideal.

However, this operation is not exactly like division. For example, when R is the ring of integers, then $(\langle 12\rangle : \langle 2\rangle) = \langle 6\rangle$, which is nice, while $(\langle 12\rangle : \langle 5\rangle) = \langle 12\rangle)$, which is not as nice.

See also ALGEBRAIC GEOMETRY, ALGEBRAIC NUMBER THEORY, IDEAL

Idele

The multiplicative subgroup of all elements in the product of the multiplicative groups $k_v^\times$ whose absolute value is 1 at all but finitely many v, where k is a number FIELD and v a PLACE.

See also ADÉLE

Idemfactor

DYADIC

Idempotent

An OPERATOR $\bar{A}$ such that $\bar{A}^2 = \bar{A}$ or an element of an ALGEBRA x such that $x^2 = x$.

See also AUTOMORPHIC NUMBER, BOOLEAN ALGEBRA, GROUP, IDEMPOTENT MATRIX, SEMIGROUP

Idempotent Matrix

A PERIODIC MATRIX with period 1, so that $\mathsf{A}^2 = \mathsf{A}$.

See also IDEMPOTENT, NILPOTENT MATRIX, PERIODIC MATRIX

Idempotent Number

The idempotent numbers are given by

$$B_{n,k}(1, 2, 3, \ldots) = \binom{n}{k} k^{n-k},$$

where $B_{n,k}$ is a BELL POLYNOMIAL and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. A table of the first few is given below.

	$n=1$	$n=2$	$n=3$	$n=4$	$n=5$	$n=6$	$n=7$
k	A000027	A001788	A036216	A040075	A050982	A050988	A050989
1	1						
2	2	1					
3	3	6	1				
4	4	24	12	1			
5	5	80	90	20	1		
6	6	240	540	240	30	1	
7	7	672	2835	2240	525	42	1
8	8	1792	13608	17920	7000	1008	56
9	9	4608	61236	129024	78750	18144	1764
10	10	11520	262440	860160	787500	272160	41160

Identical Congruence

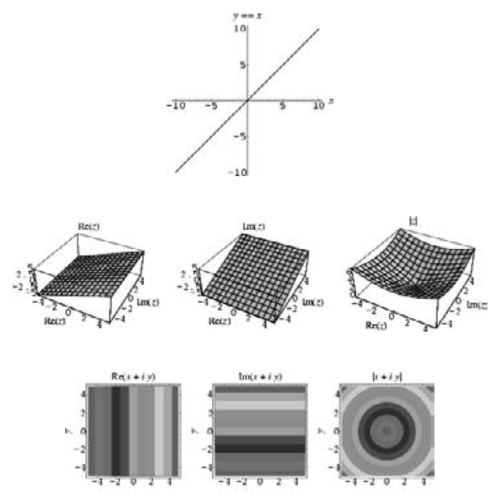
FUNCTIONAL CONGRUENCE

Identity

An identity is a mathematical relationship equating one quantity to another (which may initially appear to be different).

See also ABEL'S DIFFERENTIAL EQUATION IDENTITY, ANDREWS-SCHUR IDENTITY, BAC-CAB IDENTITY, BEAUZAMY AND DÉGOT'S IDENTITY, BELTRAMI IDENTITY, BIANCHI IDENTITIES, BOCHNER IDENTITY, BRAHMAGUPTA IDENTITY, CASSINI'S IDENTITY, CAUCHY-LAGRANGE IDENTITY, CHRISTOFFEL-DARBOUX IDENTITY, CHU-VANDERMONDE IDENTITY, DE MOIVRE'S IDENTITY, DOUGALL-RAMANUJAN IDENTITY, EULER FOUR-SQUARE IDENTITY, EULER IDENTITY, EULER POLYNOMIAL IDENTITY, FERRARI'S IDENTITY, FIBONACCI IDENTITY, FROBENIUS TRIANGLE IDENTITIES, GREEN'S IDENTITIES, HYPERGEOMETRIC IDENTITY, IMAGINARY IDENTITY, JACKSON'S IDENTITY, JACOBI IDENTITIES, JACOBI'S DETERMINANT IDENTITY, JORDAN IDENTITY, LAGRANGE'S IDENTITY, LE CAM'S IDENTITY, LEIBNIZ IDENTITY, LIOUVILLE POLYNOMIAL IDENTITY, MATRIX POLYNOMIAL IDENTITY, MORGADO IDENTITY, NEWTON'S IDENTITIES, QUINTUPLE PRODUCT IDENTITY, RAMANUJAN 6–0– IDENTITY, RAMANUJAN COS/COSH IDENTITY, RAMANUJAN'S IDENTITY, RAMANUJAN'S SUM IDENTITY, REZNIK'S IDENTITY, ROGERS-RAMANUJAN IDENTITIES, SCHAAR'S IDENTITY, STREHL IDENTITIES, SYLVESTER'S DETERMINANT IDENTITY, TRINOMIAL IDENTITY, VISIBLE POINT VECTOR IDENTITY, WATSON QUINTUPLE PRODUCT IDENTITY, WORPITZKY'S IDENTITY

References



Petkovsek, M.; Wilf, H. S.; and Zeilberger, D. "Identities." §2.2 in $A = B$. Wellesley, MA: A. K. Peters, pp. 21–2, 1996.

Identity Element

The identity element I (also denoted E, e, or I) of a GROUP or related mathematical structure S is the unique element such that $IA = AI = A$ for every element $A \in S$. The symbol "E" derives from the German word for unity, "Einheit." An identity element is also called a unit element.

See also BINARY OPERATOR, GROUP, INVOLUTION (GROUP), MONOID

Identity Function

The function $f(x) = x$ which assigns every REAL

NUMBER x to the same REAL NUMBER x. It is identical to the IDENTITY MAP.

Identity Map

The MAP which assigns every member of a set A to the same element id_A. It is identical to the IDENTITY FUNCTION.

See also DONKIN'S THEOREM, IDENTITY FUNCTION, ZERO MAP

Identity Matrix

The identity matrix is a very special BINARY MATRIX denoted I (or I) and defined such that

$$\mathsf{I}(\mathbf{X}) \equiv \mathbf{X} \tag{1}$$

for all VECTORS $\mathbf{X}$. The identity matrix is

$$I_{ij} = \delta_{ij} \tag{2}$$

for $i, j = 1, 2, \ldots, n$, where δ_{ij} is the KRONECKER DELTA. Written explicitly,

$$\mathsf{I} = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \end{bmatrix}. \tag{3}$$

The notation E (an abbreviation for the German term, "Einheitsmatrix") is sometimes also used (Courant and Hilbert 1989, p. 7).

"Square root of identity" matrices can be defined for I_n by solving

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \cdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \cdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & 0 \\ 0 & 0 & \cdots & 1 \end{bmatrix}. \tag{4}$$

For $n = 2$, the resulting matrices are

$$\mathsf{I}_2^{1/2} = \begin{bmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{bmatrix}, \begin{bmatrix} \pm 1 & 0 \\ c & \mp 1 \end{bmatrix}, \begin{bmatrix} \pm 1 & b \\ 0 & \mp 1 \end{bmatrix}, \begin{bmatrix} -d & \dfrac{1-d^2}{c^2} \\ c & d \end{bmatrix}. \tag{5}$$

"Cube root of identity" matrices can take on even more complicated forms. However, one simple class of such matrices is called K-MATRICES.

Identity Transformation

IDENTITY MAP

Identric Mean

This entry contributed by RONALD M. AARTS

The identric mean is defined by

$$I(a, b) = \frac{1}{e}\left(\frac{b^b}{a^a}\right)^{1/(b-a)}$$

for $a > 0$, $b > 0$, and $a \neq b$. The identric mean has been investigated intensively and many remarkable inequalities for $I(a, b)$ have been published (Bullen *et al.* 1988, Alzer 1993).

Idoneal Number

A POSITIVE value of D for which the fact that a number is a MONOMORPH (i.e., the number is expressible in only one way as $x^2 + Dy^2$ or $x^2 - Dy^2$ where x^2 is RELATIVELY PRIME to Dy^2) guarantees it to be a PRIME, POWER of a PRIME, or twice one of these. The numbers are also called EULER'S IDONEAL NUMBERS, or SUITABLE NUMBERS.

The 65 idoneal numbers found by Gauss and Euler and conjectured to be the *only* such numbers (Shanks 1969) are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 13, 15, 16, 18, 21, 22, 24, 25, 28, 30, 33, 37, 40, 42, 45, 48, 57, 58, 60, 70, 72, 78, 85, 88, 93, 102, 105, 112, 120, 130, 133, 165, 168, 177, 190, 210, 232, 240, 253, 273, 280, 312, 330, 345, 357, 385, 408, 462, 520, 760, 840, 1320, 1365, and 1848 (Sloane's A000926).

Iff

If and only if (i.e., NECESSARY and SUFFICIENT). The terms "JUST IF" or "EXACTLY WHEN" are sometimes used instead. A iff B is written symbolically as $A \leftrightarrow B$. A iff B is also equivalent to $A \Rightarrow B$, together with $B \Rightarrow A$, where the symbol $\Rightarrow$ denotes "IMPLIES."

J. H. Conway believes that the word originated with P. Halmos and was transmitted through Kelley (1975). Halmos has stated, "To the best of my knowledge, I *did* invent the silly thing, but I wouldn't swear to it in a court of law. So there–give me credit for it anyway" (D. Asimov 1997).

See also EQUIVALENT, EXACTLY ONE, IMPLIES, NECESSARY, SUFFICIENT

Ill-Conditioned Matrix

A MATRIX is ill-conditioned if the CONDITION NUMBER is too large (and SINGULAR if it is INFINITE).

See also CONDITION NUMBER, SINGULAR MATRIX, SINGULAR VALUE DECOMPOSITION

References

Arfken, G. "Ill-Conditioned Systems." *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 233–34, 1985.

Ill Defined

A solution to a PARTIAL DIFFERENTIAL EQUATION that is *not* a continuous function of its values on the boundary is said to be ill defined. Otherwise, a solution is called WELL DEFINED.

The term "ill defined" is also used informally to mean AMBIGUOUS.

See also AMBIGUOUS, WELL DEFINED

Illumination Problem

In the early 1950s, Ernst Straus asked

1. Is every POLYGONAL region illuminable from every point in the region?
2. Is every POLYGONAL region illuminable from at least one point in the region?

Here, illuminable means that there is a path from every point to every other by repeated reflections. Tokarsky (1995) showed that unilluminable rooms exist in the plane and 3-D, but question (2) remains open. The smallest known counterexample to (1) in the PLANE has 26 sides.

Im

IMAGINARY PART

Image

RANGE (IMAGE)

Imaginary Axis

The axis in the COMPLEX PLANE corresponding to zero REAL PART, $\Re[z]=0$.

See also COMPLEX PLANE, IMAGINARY LINE, REAL AXIS

Imaginary Identity

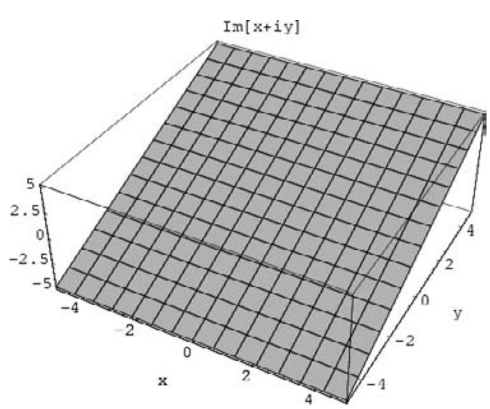
I

Imaginary Line

A "line" having imaginary coefficients in its equations which can arise in algebraic geometry.

See also IMAGINARY AXIS, LINE, REAL LINE

Imaginary Number



A COMPLEX NUMBER which has zero REAL PART, so that it can be written as a REAL NUMBER multiplied by the "IMAGINARY UNIT" I (equal to the SQUARE ROOT $\sqrt{-1}$).

See also COMPLEX NUMBER, GALOIS IMAGINARY, GAUSSIAN INTEGER, I, IMAGINARY PART, IMAGINARY UNIT, REAL NUMBER

References

Conway, J. H. and Guy, R. K. *The Book of Numbers.* New York: Springer-Verlag, pp. 211–16, 1996.

Imaginary Part

The imaginary part $\Im[z]$ of a COMPLEX NUMBER $z=x+iy$ is the REAL NUMBER multiplying I, so $\Im[x+iy]=y$. In terms of z itself,

$$\Im[z]=\frac{z-\bar{z}}{2i},$$

where $\bar{z}$ is the COMPLEX CONJUGATE of z. The imaginary part is implemented in *Mathematica* as `Im[z]`.

Imaginary Point

A pair of values x and y one or both of which is COMPLEX.

References

Woods, F. S. *Higher Geometry: An Introduction to Advanced Methods in Analytic Geometry.* New York: Dover, p. 2, 1961.

Imaginary Quadratic Field

A QUADRATIC FIELD $\mathbb{Q}(\sqrt{D})$ with $D<0$.

See also JUGENDTRAUM, QUADRATIC FIELD

Imaginary Unit

The IMAGINARY NUMBER $i=\sqrt{-1}$, i.e., the SQUARE ROOT of -1. The imaginary unit is denoted and commonly referred to as "I." Although there are two possible square roots of any number, the square roots of a negative number cannot be distinguished until one of the two is defined as the imaginary unit, at which point $+i$ and $-i$ can then be distinguished. Since either choice is possible, there is no ambiguity in defining i as "the" square root of -1. In *Mathematica*, the imaginary unit is implemented as `I`.

See also COMPLEX NUMBER, I, IMAGINARY NUMBER, UNIT

Immanant

For an $n\times n$ matrix, let S denote any permutation e_1, e_2, ..., e_n of the set of numbers 1, 2, ..., n, and let $\chi^{(\lambda)}(S)$ be the character of the symmetric group corresponding to the partition (λ). Then the immanant $|a_{mn}|^{(\lambda)}$ is defined as

$$|a_{mn}|^{(\lambda)}=\sum\chi^{(\lambda)}(S)P_S$$

where the summation is over the $n!$ permutations of

the SYMMETRIC GROUP and

$$P_S = a_{1e_1} a_{2e_2} \cdots a_{ne_n}.$$

Immersed Minimal Surface

ENNEPER'S MINIMAL SURFACE

Immersion

A special nonsingular MAP from one MANIFOLD to another such that at every point in the domain of the map, the DERIVATIVE is an injective linear map. This is equivalent to saying that every point in the DOMAIN has a NEIGHBORHOOD such that, up to DIFFEOMORPHISMS of the TANGENT SPACE, the map looks like the inclusion map from a lower-dimensional EUCLIDEAN SPACE to a higher-dimensional EUCLIDEAN SPACE.

See also BOY SURFACE, EVERSION, SMALE-HIRSCH THEOREM, SUBMERSION

Immersion Theorem

SMALE-HIRSCH THEOREM

Impartial Game

A GAME in which the possible moves are the same for each player in any position. All positions in all impartial GAMES form an additive ABELIAN GROUP. For impartial games in which the last player wins (normal form games), the nim-value of the sum of two GAMES is the nim-sum of their nim-values. If the last player loses, the GAME is said to be in misère form and the analysis is much more difficult.

See also FAIR GAME, GAME, PARTISAN GAME

Implicit Function

A function which is not defined explicitly, but rather is defined in terms of an algebraic relationship (which can not, in general, be "solved" for the function in question). For example, the ECCENTRIC ANOMALY E of a body orbiting on an ELLIPSE with ECCENTRICITY e is defined implicitly in terms of the mean anomaly M by KEPLER'S EQUATION

$$\mathrm{M} = E - e \sin E.$$

Implicit Function Theorem

Given

$$F_1(x,y,z,u,v,w) = 0 \quad (1)$$

$$F_2(x,y,z,u,v,w) = 0 \quad (2)$$

$$F_3(x,y,z,u,v,w) = 0 \quad (3)$$

if the JACOBIAN

$$JF(u,v,w) = \frac{\partial(F_1,F_2,F_3)}{\partial(u,v,w)} \neq 0, \quad (4)$$

then u, v, and w can be solved for in terms of x, y, and z and PARTIAL DERIVATIVES of u, v, w with respect to x, y, and z can be found by differentiating implicitly.

More generally, let A be an OPEN SET in $\mathbb{R}^{n+k}$ and let $f: A \to \mathbb{R}^n$ be a C^τ FUNCTION. Write f in the form $f(x,y)$, where x and y are elements of $\mathbb{R}^k$ and $\mathbb{R}^n$. Suppose that (a, b) is a point in A such that $f(a,b) = 0$ and the DETERMINANT of the $n \times n$ MATRIX whose elements are the DERIVATIVES of the n component FUNCTIONS of f with respect to the n variables, written as y, evaluated at (a, b), is not equal to zero. The latter may be rewritten as

$$\operatorname{rank}(Df(a,b)) = n. \quad (5)$$

Then there exists a NEIGHBORHOOD B of a in $\mathbb{R}^k$ and a unique C^τ FUNCTION $g: B \to \mathbb{R}^n$ such that $g(a) = b$ and $f(x, g(x)) = 0$ for all $x \in B$.

See also CHANGE OF VARIABLES THEOREM, JACOBIAN

References

Munkres, J. R. *Analysis on Manifolds.* Reading, MA: Addison-Wesley, 1991.

Implies

The CONNECTIVE in PROPOSITIONAL CALCULUS which has the meaning "if A is true, then B is also true." In formal terminology, the term CONDITIONAL is often used to refer to this connective (Mendelson 1997, p. 13). The symbol used to denote "implies" is $A \Rightarrow B$, $A \supset B$ (Carnap 1958, p. 8; Mendelson 1997, p. 13), or $A \to B$. In *Mathematica* 4.0, the command `ImpliesRealQ[`*ineqs1*, *ineqs2*`]` can be used to determine if the system of real algebraic equations and inequalities *ineqs1* implies the system of real algebraic equations and inequalities *ineqs2*.

$A \Rightarrow B$ is an abbreviation for $!A \vee B$, where $!A$ denotes NOT and $\vee$ denoted OR. $\Rightarrow$ is a binary operator that is implement in *Mathematica* as `Implies[A, B]`, and can *not* be extended to more than two arguments.

$A \Rightarrow B$ has the following TRUTH TABLE (Carnap 1958, p. 10; Mendelson 1997, p. 13).

A	B	$A \Rightarrow B$
T	T	T
T	F	F
F	T	T
F	F	T

If $A \Rightarrow B$ and $B \Rightarrow A$ (i.e, $A \Rightarrow B \wedge B \Rightarrow A$), then A and B are said to be EQUIVALENT, a relationship which is written symbolically as $A \Leftrightarrow B$, $A \rightleftharpoons B$, or $A \equiv B$ (Carnap 1958, p. 8).

Impredicative

Definitions about a SET which depend on the entire SET.

Improper Divisor

A DIVISOR which is not a PROPER DIVISOR.

See also DIVISOR, PROPER DIVISOR

Improper Fraction

A FRACTION $p/q > 1$. A FRACTION with $p/q < 1$ is called a PROPER FRACTION. Therefore, the special cases 1/1, 2/2, 3/3, etc. are generally considered to be improper.

See also FRACTION, MIXED FRACTION, PROPER FRACTION

Improper Integral

An INTEGRAL which has either or both limits INFINITE or which has an INTEGRAND which approaches INFINITY at one or more points in the range of integration.

See also DEFINITE INTEGRAL, INDEFINITE INTEGRAL, INTEGRAL, PROPER INTEGRAL

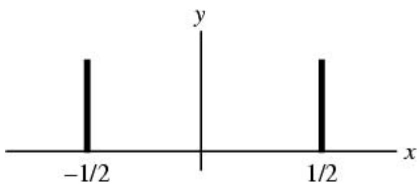
Improper Node

A FIXED POINT for which the STABILITY MATRIX has equal nonzero EIGENVECTORS.

See also STABLE IMPROPER NODE, UNSTABLE IMPROPER NODE



Improper Rotation

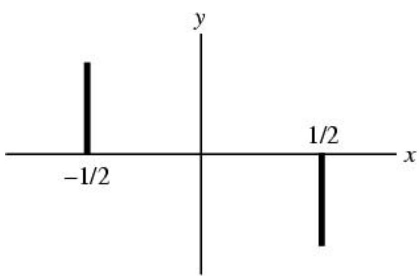
The SYMMETRY OPERATION corresponding to a ROTATION followed by an INVERSION OPERATION, also called a ROTOINVERSION. This operation is denoted $\bar{n}$ for an improper rotation by $360°/n$ so the CRYSTALLOGRAPHY RESTRICTION gives only $\bar{1}$, $\bar{2}$, $\bar{3}$, $\bar{4}$, $\bar{6}$ for crystals. The

MIRROR PLANE symmetry operation is $(x, y, z) \rightarrow (x, y, -z)$, etc., which is equivalent to $\bar{2}$.

See also INVERSION OPERATION, ROTATION, SYMMETRY OPERATION

Impulse Pair

The even impulse pair is the FOURIER TRANSFORM of $\cos(\pi k)$,



$$\Pi(x) \equiv \tfrac{1}{2}\delta\left(x+\tfrac{1}{2}\right)+\tfrac{1}{2}\delta\left(x-\tfrac{1}{2}\right). \quad (1)$$

It satisfies

$$\Pi(x) * f(x) = \tfrac{1}{2}f\left(x+\tfrac{1}{2}\right)+\tfrac{1}{2}f\left(x-\tfrac{1}{2}\right), \quad (2)$$

where $*$ denotes CONVOLUTION, and

$$\int_{-\infty}^{\infty} \Pi(x)\,dx = 1. \quad (3)$$

The odd impulse pair is the FOURIER TRANSFORM of $i \sin(\pi s)$,

$$I_I(x) \equiv \tfrac{1}{2}\delta\left(x+\tfrac{1}{2}\right)-\tfrac{1}{2}\delta\left(x-\tfrac{1}{2}\right). \quad (4)$$

Impulse Symbol

Bracewell's term for the DELTA FUNCTION.

See also DELTA FUNCTION, IMPULSE PAIR

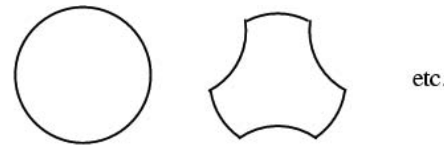
Inaccessible Cardinal

An inaccessible cardinal is a CARDINAL NUMBER which cannot be expressed in terms of a smaller number of smaller cardinals.

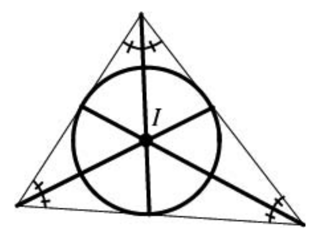
See also CARDINAL NUMBER



Inaccessible Cardinals Axiom

INACCESSIBLE CARDINAL, LEBESGUE MEASURABILITY PROBLEM

Inadmissible



A word or string which is not ADMISSIBLE.

In-and-Out Curve

A curve created by starting with a circle, dividing it into six arcs, and flipping three alternating arcs. The process is then repeated an infinite number of times.

Incenter

The center I of a TRIANGLE'S INCIRCLE. It can be found as the intersection of ANGLE BISECTORS, and it is the interior point for which distances to the sides of the triangle are equal. It has TRILINEAR COORDINATES 1:1:1 and homogeneous BARYCENTRIC COORDINATES (a, b, c). The distance between the incenter and CIRCUMCENTER is $\sqrt{R(R-2r)}$.
The incenter lies on the NAGEL LINE and SODDY LINE. The incenter lies on the EULER LINE only for an ISOSCELES TRIANGLE. For an EQUILATERAL TRIANGLE, the CIRCUMCENTER O, CENTROID G, NINE-POINT CENTER F, ORTHOCENTER H, and DE LONGCHAMPS POINT Z all coincide with I.

The incenter and EXCENTERS of a TRIANGLE are an ORTHOCENTRIC SYSTEM. The POWER of the incenter with respect to the CIRCUMCIRCLE is

$$p = \frac{a_1 a_2 a_3}{a_1 + a_2 + a_3}$$

(johnson 1929, p. 190). if the incenters of the TRIANGLES $\Delta A_1H_2H_3$, $\Delta A_2H_3A_1$, and $\Delta A_3H_1H_2$ are X_1, X_2, and X_3, then X_2X_3 is equal and parallel to I_2I_3, where H_i are the FEET of the ALTITUDES and I_i are the incenters of the TRIANGLES. Furthermore, X_1, X_2, X_3, are the reflections of I with respect to the sides of the TRIANGLE $\Delta I_1I_2I_3$ (Johnson 1929, p. 193).

Incenter-Excenter Circle

Given a triangle $\Delta A_1A_2A_3$, the points A_1, I, and J_1 lie on a line, where I is the INCENTER and J_1 is the EXCENTER corresponding to A_1. Furthermore, the CIRCLE with IJ_1 as the DIAMETER has P as its center, where P is the intersection of A_1J_1 with the CIRCUMCIRCLE of $\Delta A_1A_2A_3$, and passes through A_2 and A_3. This CIRCLE has RADIUS

$$r = \tfrac{1}{2}a_1 \sec\left(\tfrac{1}{2}\alpha_1\right) = 2R \sin\left(\tfrac{1}{2}\alpha_1\right).$$

It arises because $IJ_1J_2J_3$ forms an ORTHOCENTRIC SYSTEM.

Incidence Matrix

$$\begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix} \quad \begin{pmatrix} 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \end{pmatrix} \quad \begin{pmatrix} 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix}$$

The incidence matrix of a GRAPH gives the (0,1)-MATRIX which has a row for each vertex and column for each edge, and $(v, e) = 1$ IFF vertex v is incident upon edge e (Skiena 1990, p. 135). The physicist Kirchhoff (1847) was the first to define the incidence matrix. The incidence matrix of a graph can be computed using `IncidenceMatrix[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

The incidence matrix C of a graph and ADJACENCY MATRIX L of its LINE GRAPH are related by

$$\mathsf{L} = \mathsf{C}^{\mathrm{T}}\mathsf{C} - 2\mathsf{I},$$

where I is the IDENTITY MATRIX (Skiena 1990, p. 136).

For a k-D POLYTOPE Π_k, the incidence matrix is defined by

$$\eta_{ij}^k = \begin{cases} 1 & \text{if } \Pi_{k-1}^i \text{ belongs to } \Pi_k^i \\ 0 & \text{if } \Pi_{k-1}^i \text{ does not belong } \Pi_k^i \end{cases}$$

The ith row shows which Π_ks surround Π_{k-1}^i, and the jth column shows which Π_{k-1}s bound Π_k^j. Incidence matrices are also used to specify PROJECTIVE PLANES. The incidence matrices for a TETRAHEDRON $ABCD$ are

η^0	1	A	B	C
1	1	1	1	1

η^1	AD	BD	CD	BC	AC	AB
A	1	0	0	0	1	1
B	0	1	0	1	0	1
C	0	0	1	1	1	0
D	1	1	1	0	0	0

η^2	BCD	ACD	ABD	ABC
AD	0	1	1	0
BD	1	0	1	0
CD	1	1	0	0
BC	1	0	0	1
AC	0	1	0	1
AB	0	0	1	1

η^3	$ABCD$
BCD	1
ACD	1
ABD	1
ABC	1

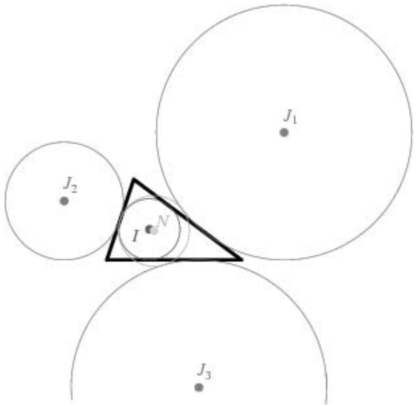
Incident



Two objects which touch each other are said to be incident.

See also CONCUR, TANGENT CURVES

Incircle

The INSCRIBED CIRCLE of a TRIANGLE ΔABC. The center I of the incircle is called the INCENTER and the RADIUS r the INRADIUS. The points of intersection of the incircle with T are the VERTICES of the PEDAL TRIANGLE of T with the INCENTER as the PEDAL POINT (cf. TANGENTIAL TRIANGLE). This TRIANGLE is called the CONTACT TRIANGLE.

There are four CIRCLES that are tangent all three sides (or their extensions) of a given TRIANGLE: the incircle I and three EXCIRCLES J_1, J_2, and J_3. These four circles are, in turn, all touched by the NINE-POINT CIRCLE N.

The TRILINEAR COORDINATES of the INCENTER are $1:1:1$. The INRADIUS r and horizontal position of the INCENTER x_I for a given triangle with two angles A and C and adjacent side of length b is given by simultaneously solving the equations

$$\tan\left(\tfrac{1}{2}A\right)=\frac{r}{x_I} \quad (1)$$

$$\tan\left(\tfrac{1}{2}C\right)=\frac{r}{b-x_I}, \quad (2)$$

giving

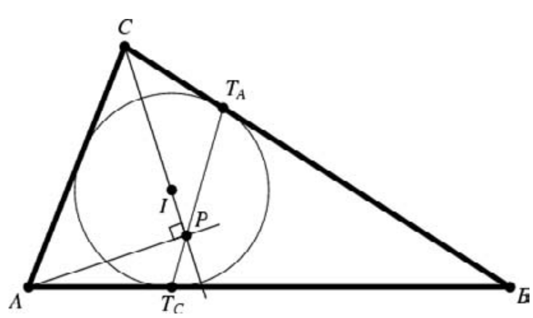
$$r = \frac{\tan\left(\frac{1}{2}A\right)\tan\left(\frac{1}{2}C\right)}{\tan\left(\frac{1}{2}A\right) + \tan\left(\frac{1}{2}C\right)} b \tag{3}$$

$$x_I = \frac{\tan\left(\frac{1}{2}C\right)}{\tan\left(\frac{1}{2}A\right) + \tan\left(\frac{1}{2}C\right)} b, \tag{4}$$

whereas the ALTITUDE height h and horizontal position x_h of the ALTITUDE, are given by

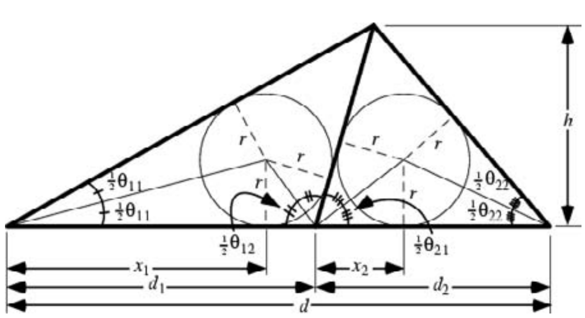
$$h = \frac{\tan C}{\tan A + \tan C} b \tag{5}$$

$$x_h = \frac{\tan A \tan C}{\tan A + \tan C} b. \tag{6}$$



The AREA Δ of the TRIANGLE ΔABC is given by

$$\begin{aligned} \Delta &= \Delta BIC + \Delta AIC + \Delta AIB \\ &= \tfrac{1}{2}ar + \tfrac{1}{2}br + \tfrac{1}{2}cr = \tfrac{1}{2}(a+b+c)r = sr, \end{aligned} \tag{7}$$



where s is the SEMIPERIMETER, so the INRADIUS is

$$r = \frac{\Delta}{s} = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}} \tag{8}$$

Using the incircle of a TRIANGLE as the INVERSION CENTER, the sides of the TRIANGLE and its CIRCUMCIRCLE are carried into four equal CIRCLES (Honsberger 1976, p. 21). Pedoe (1995, p. xiv) gives a GEOMETRIC CONSTRUCTION for the incircle.

Let a triangle ΔABC have INCIRCLE with INCENTER I and let the incircle be tangent to ΔABC at T_A, T_C, (and T_B; not shown). Then the lines CI, $T_A T_C$, and the perpendicular to CI through A CONCUR in a point P (Honsberger 1995).

Given a triangle, draw a CEVIAN to one of the bases which divides it into two triangles having congruent incircles. The positions and sizes of these two circumcircles can then be determined by simultaneously solving the eight equations

$$x_1 = \frac{\tan\left(\frac{1}{2}\theta_{12}\right)}{\tan\left(\frac{1}{2}\theta_{11} + \tan\left(\frac{1}{2}\theta_{12}\right)\right)} d_1 \tag{9}$$

$$x_2 = \frac{\tan\left(\frac{1}{2}\theta_{22}\right)}{\tan\left(\frac{1}{2}\theta_{21}\right) + \tan\left(\frac{1}{2}\theta_{22}\right)} d_2 \tag{10}$$

$$a = \frac{\tan\left(\frac{1}{2}\theta_{11}\right)\tan\left(\frac{1}{2}\theta_{12}\right)}{\tan\left(\frac{1}{2}\theta_{11}\right) + \tan\left(\frac{1}{2}\theta_{12}\right)} d_1 \tag{11}$$

$$a = \frac{\tan\left(\frac{1}{2}\theta_{21}\right)\tan\left(\frac{1}{2}\theta_{22}\right)}{\tan\left(\frac{1}{2}\theta_{21}\right) + \tan\left(\frac{1}{2}\theta_{22}\right)} d_2 \tag{12}$$

$$h = \frac{\tan\theta_{11}\tan\theta_{12}}{\tan\theta_{11} + \tan\theta_{12}} d_1 \tag{13}$$

$$h = \frac{\tan\theta_{21}\tan\theta_{22}}{\tan\theta_{21} + \tan\theta_{22}} d_2 \tag{14}$$

$$d = d_1 + d_2 \tag{15}$$

$$\pi = \theta_{12} + \theta_{21} \tag{16}$$

for the eight variables d_1, d_2, θ_{12}, θ_{21}, a, x_1, x_2, and h, with θ_{11}, θ_{22}, and d given. Generalizing to n congruent circles gives the $4n$ equations

$$x_i = \frac{\tan\left(\frac{1}{2}\theta_{i2}\right)}{\tan\left(\frac{1}{2}\theta_{i1}\right) + \tan\left(\frac{1}{2}\theta_{i2}\right)} d_i \tag{17}$$

$$a = \frac{\tan\left(\frac{1}{2}\theta_{i1}\right)\tan\left(\frac{1}{2}\theta_{i2}\right)}{\tan\left(\frac{1}{2}\theta_{i1}\right) + \tan\left(\frac{1}{2}\theta_{i2}\right)} d_i \tag{18}$$

$$h = \frac{\tan\theta_{i1}\tan\theta_{i2}}{\tan\theta_{i1} + \tan\theta_{i2}} d_i \tag{19}$$

for $i = 1, \ldots, n$,

$$\theta_{i2} + \theta_{i+1,1} = \pi \tag{20}$$

for $i = 1, \ldots, n-1$, and

$$d = \sum_{i=1}^{n} d_i \tag{21}$$

to be solved for the unknowns d_i and x_i (n of them), θ_{i1} and θ_{i2} ($n-2$ of each for $i = 2, \ldots, n-1$), and θ_{12}, θ_{n1}, a, and h, a total of $n + n + 2(n-2) + 4 = 4n$ unknowns.

Given an arbitrary TRIANGLE, let $n-1$ Cevians be drawn from one of its vertices so all of the n triangles

so determined have equal incircles. Then the incircles determined by spanning 2, 3, ..., $n-1$ adjacent triangles are also equal (Wells 1991, p. 67).

Inclusion Map

Given a SUBSET B of a SET A, the INJECTION $f: B \to A$ defined by $f(b)=b$ for all $b \in B$ is called the inclusion map.

See also LONG EXACT SEQUENCE OF A PAIR AXIOM

Inclusion-Exclusion Principle

Let $|A|$ denote the CARDINALITY of set A, then it follows immediately that

$$|A \cup B| = |A| + |B| - |A \cap B|,$$

where $\cup$ denotes UNION, and $\cap$ denotes INTERSECTION.

This formula can be generalized in the following beautiful manner. Let $\mathscr{A} = \{A_i\}_{i=1}^{p}$ be a P-SYSTEM of S consisting of sets $A_1, \ldots, A_p$, then

$$|A_1 \cup A_2 \cup \ldots \cup A_p| = \sum_{1 \le i \le p} |A_i| - \sum_{1 \le i_1 < i_2 \le p} |A_{i1} \cap A_{i2}|$$
$$+ \sum_{1 \le i_1 < i_2 < i_3 \le p} |A_{i1} \cap A_{i2} \cap A_{i3}| - \ldots$$
$$+ (-1)^{p-1} |A_{i1} \cap A_{i2} \cap \ldots \cap A_p|,$$

where the sums are taken over K-SUBSETS of $\mathscr{A}$. This formula holds for infinite sets S as well as finite sets (Comtet 1972, p. 177).

The principle of inclusion-exclusion was used by Nicholas Bernoulli to solve the recontres problem of finding the number of DERANGEMENTS (Bhatnagar 1995, p. 8).

The following *Mathematica* programs give a list of the subsets appearing under each sum and the contribution each sum makes to the total.

```
<<             DiscreteMath`Combinatorica`;
InclusionExclusionSubets[a_List]         :=
Module[{n, p = Length[a]},
   Table[Intersection @@ a[[#]] & /@
    KSubsets[Range[p], n],
   {n, p}]
    ]     InclusionExclusionTerms[a_List]   :=
Module[{n, p = Length[a]},
    Table[(-1)^(n - 1)Plus @@      Length /@
(Intersection @@ a[[#]] & /@
      KSubsets[Range[p], n]),
   {n, p}]
  ]
```

For example, for the three subsets $A_1 = \{2, 3, 7, 9, 10\}$, $A_2 = \{1, 2, 3, 9\}$, and $A_3 = \{2, 4, 9, 10\}$ of $S = \{1, 2, \ldots, 10\}$, the following table summarizes the terms appearing the sum.

#	term	set	length
1	A_1	{2, 3, 7, 9, 10}	5
	A_2	{1, 2, 3, 9}	4
	A_3	{2, 4, 9, 10}	4
2	$A_1 \cap A_2$	{2, 3, 9}	3
	$A_1 \cap A_3$	{2, 9, 10}	3
	$A_2 \cap A_3$	{2, 9}	2
3	$A_1 \cap A_2 \cap A_3$	{2, 9}	2

$|A_1 \cup A_2 \cup A_3|$ is therefore equal to $(5+4+4)-(3+3+2)+2=7$, corresponding to the seven elements $A_1 \cup A_2 \cup A_3 = \{1, 2, 3, 4, 7, 9, 10\}$.

Inclusive Disjunction

A DISJUNCTION that remains true if either *or both* of its arguments are true. This is equivalent to the OR CONNECTIVE.

By contrast, the EXCLUSIVE DISJUNCTION is true if only one, but not both, of its arguments are true, and is false if neither or both are true, which is equivalent to the XOR connective.

See also DISJUNCTION, EXCLUSIVE DISJUNCTION, OR, XOR

Incommensurate

Two lengths are called incommensurate or incommensurable if their ratio cannot be expressed as a ratio of whole numbers. IRRATIONAL NUMBERS and TRANSCENDENTAL NUMBERS are incommensurate with the integers.

See also FRACTION, IRRATIONAL NUMBER, PYTHAGORAS'S CONSTANT, TRANSCENDENTAL NUMBER

Incomparable Rectangles

Two RECTANGLES, neither of which will fit inside the other, are said to be incomparable. This is equivalent to one rectangle being both longer and narrower. At least seven and at most eight mutually incomparable rectangles are needed to tile a given rectangle (Wells 1991).

See also RECTANGLE

Incomplete Beta Function

A generalization of the complete BETA FUNCTION defined by

$$B(z;a,b) \equiv \int_0^z u^{a-1}(1-u)^{b-1}du$$

$$= z^a \left[\frac{1}{a} + \frac{1-b}{a+1}z + \ldots + \frac{(1-b)\cdots(n-b)}{n!(a+n)}z^n + \ldots\right].$$

The symbol $B_z(a,b)$ is sometimes also used. The incomplete beta function $B(z;a,b)$ reduces to the use BETA FUNCTION $B(a,b)$ when $z=1$,

$$B(1;a,b) = B(a,b)$$

The incomplete beta function is implemented in *Mathematica* as `Beta[z, a, b]`.

See also BETA FUNCTION, REGULARIZED BETA FUNCTION

Incomplete Gamma Function

The "complete" GAMMA FUNCTION $\Gamma(x)$ can be generalized to the incomplete gamma function $\Gamma(a,x)$ such that $\Gamma(a) = \Gamma(a,0)$. This "upper" incomplete gamma function is given by

$$\Gamma(a,x) \equiv \int_x^\infty t^{a-1}e^{-t}dt. \tag{1}$$

For a an INTEGER n

$$\Gamma(n,x) = (n-1)!e^{-x}\sum_{s=0}^{n-1}\frac{x^s}{s!} = (n-1)!e^{-x}e_{n-1}(x), \tag{2}$$

where es is the EXPONENTIAL SUM FUNCTION. The lower incomplete gamma function is given by

$$\gamma(a,x) \equiv \int_0^x t^{a-1}e^{-t}dt$$

$$a^{-1}x^a e^{-x}\,{}_1F_1(1;1+a;x)$$

$$a^{-1}x^a\,{}_1F_1(a;1+a;-x), \tag{3}$$

where ${}_1F_1(a;b;x)$ is the CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND. For a an INTEGER n,

$$\gamma(n,x) = (n-1)!\left(1 - e^{-x}\sum_{k=0}^{n-1}\frac{x^k}{k!}\right)$$

$$= (n-1)![1 - e^{-x}e_{n-1}(x)]. \tag{4}$$

The function $\Gamma(a,z)$ is denoted `Gamma[a, z]` and the function $\gamma(a,z)$ is denoted `Gamma[a, 0, z]` in *Mathematica*. By definition, the two incomplete functions satisfy

$$\Gamma(a,x) + \gamma(a,x) = \Gamma(a). \tag{5}$$

See also GAMMA FUNCTION, REGULARIZED GAMMA FUNCTION

Incompleteness

A formal theory is said to be incomplete if it contains fewer theorems than would be possible while still retaining CONSISTENCY.

See also CONSISTENCY, GÖDEL'S INCOMPLETENESS THEOREM

References

Chaitin, G. J. "G. J. Chaitin's Home Page." http://www.cs.auckland.ac.nz/CDMTCS/chaitin/.

Increasing Function

A function $f(x)$ increases on an INTERVAL I if $f(b) > f(a)$ for all $b > a$, where $a, b \in I$. Conversely, a function $f(x)$ decreases on an INTERVAL I if $f(b) < f(a)$ for all $b > a$ with $a, b \in I$.

If the DERIVATIVE $f'(x)$ of a CONTINUOUS FUNCTION $f(x)$ satisfies $f'(x) > 0$ on an OPEN INTERVAL (a, b), then $f(x)$ is increasing on (a, b). However, a function may increase on an interval without having a derivative defined at all points. For example, the function $x^{1/3}$ is increasing everywhere, including the origin $x = 0$, despite the fact that the DERIVATIVE is not defined at that point.

See also DECREASING FUNCTION, DERIVATIVE, NONDECREASING FUNCTION, NONINCREASING FUNCTION

References

Jeffreys, H. and Jeffreys, B. S. "Increasing and Decreasing Functions." §1.065 in *Methods of Mathematical Physics, 3rd ed.* Cambridge, England: Cambridge University Press, p. 22, 1988.

Increasing Sequence

For a SEQUENCE $\{a_n\}$, if $a_{n+1} - a_n > 0$ for $n \geq x$, then a_n is increasing for $n \geq x$. Conversely, if $a_{n+1} - a_n < 0$ for $n \geq x$, then a_n is DECREASING for $n \geq x$.

If $a_n > 0$ and $a_{n+1}/a_n > 1$ for all $n \geq x$, then a_n is increasing for $n \geq x$. Conversely, if $a_n > 0$ and $a_{n+1}/a_n < 1$ for all $n \geq x$, then a_n is decreasing for $n \geq x$.

See also DECREASING SEQUENCE, SEQUENCE

Indecomposable

A P-FORM α is indecomposable if it cannot be written as the WEDGE PRODUCT of ONE-FORMS

$$\alpha = \beta_1 \wedge \ldots \wedge \beta_p.$$

A p-form that can be written as such a product is called DECOMPOSABLE.

See also DECOMPOSABLE, DIFFERENTIAL K-FORM

Indefinite Integral

An INTEGRAL

$$\int f(x) dx$$

without upper and lower limits, also called an ANTIDERIVATIVE. The first FUNDAMENTAL THEOREM OF CALCULUS allows DEFINITE INTEGRALS to be computed in terms of indefinite integrals. If F is the indefinite integral for $f(x)$, then

$$\int_a^b f(x) dx = F(b) - F(a).$$

The question of which definite integrals can be expressed in terms of elementary function is not susceptible to any established theory. In fact, the problem belongs to transcendence theory, which appears to be "infinitely hard." For example, there are definite integrals that are equal to the EULER-MASCHERONI CONSTANT γ. However, the problem of deciding whether γ can be expressed in terms of the values at rational values of elementary functions involves the decision as to whether γ is rational or algebraic, which is not known.

Indefinite Quadratic Form

A QUADRATIC FORM $Q(\mathbf{x})$ is indefinite if it is less than 0 for some values and greater than 0 for others. The QUADRATIC FORM, written in the form $(\mathbf{x}, \mathsf{A}\mathbf{x})$, is indefinite if EIGENVALUES of the MATRIX A are of both signs.

See also POSITIVE DEFINITE QUADRATIC FORM, POSITIVE SEMIDEFINITE QUADRATIC FORM

Indefinite Summation Operator

The indefinite summation operator Δ^{-1} for discrete variables, is the equivalent of integration for continuous variables. If $\Delta Y(x) = y(x)$ then $\Delta^{-1} y(x) = Y(x)$.

Indegree

The number of inward directed EDGES from a given VERTEX in a DIRECTED GRAPH.

See also LOCAL DEGREE, OUTDEGREE

Independence Axiom

A rational choice between two alternatives should depend only on how they differ.

Independence Complement Theorem

If sets E and F are INDEPENDENT, then so are E and F', where F' is the complement of F (i.e., the set of all possible outcomes not contained in F). Let $\cup$ denote "or" and $\cap$ denote "and." Then

$$P(E) = P(EF \cup EF') \quad (1)$$

$$= P(EF) + P(EF') - P(EF \cap EF'), \quad (2)$$

where AB is an abbreviation for $A \cap B$. But E and F are independent, so

$$P(EF) = P(E)P(F). \quad (3)$$

Also, since F and F' are complements, they contain no

common elements, which means that

$$P(EF \cap EF') = 0 \tag{4}$$

for any E. Plugging (4) and (3) into (2) then gives

$$P(E) = P(E)P(F) + P(EF'). \tag{5}$$

Rearranging,

$$P(EF') = P(E)[1 - P(F)] = P(E)P(F'), \tag{6}$$

Q.E.D.

See also INDEPENDENT SET

Independence Number

The independence number $\alpha(G)$ of a graph is the cardinality of the largest INDEPENDENT SET. Formally,

$$\alpha(G) = \max(|U| : U \subset V \text{ independent})$$

for a GRAPH G, where $|U|$ denotes the CARDINALITY of the set U. The independence number of the DE BRUIJN GRAPH of order n is given by 1, 2, 3, 7, 13, 28, ... (Sloane's A006946).

By definition, the independence number of a graph G plus the number of elements in a minimal VERTEX COVER of G equals the number of vertices in the graph.

See also INDEPENDENT SET, VERTEX COVER

Independent Equations

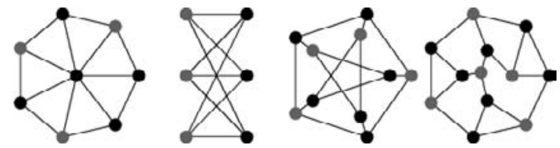
LINEARLY INDEPENDENT

Independent Events

Two events A and B are called independent if their probabilities satisfy $P(AB) = P(A)P(B)$ (Papoulis 1984, p. 40).

See also EVENT, INDEPENDENT STATISTICS

References



Papoulis, A. *Probability, Random Variables, and Stochastic Processes, 2nd ed.* New York: McGraw-Hill, 1984.

Independent Sequence

STRONGLY INDEPENDENT, WEAKLY INDEPENDENT

Independent Set

Two sets A and B are said to be independent if their INTERSECTION $A \cap B = \emptyset$, where $\emptyset$ is the EMPTY SET. For example, $\{A, B, C\}$ and $\{D, E\}$ are independent, but $\{A, B, C\}$ and $\{C, D, E\}$ are not. Independent sets are also called DISJOINT or mutually exclusive.

An independent set of a GRAPH G is a subset of the vertices such that no two vertices in the subset represent an edge of G. Given a VERTEX COVER of a GRAPH, all vertices not in the cover define an independent set (Skiena 1990, p. 218). The INDEPENDENCE NUMBER of a graph is the cardinality of the largest independent set. A maximum independent set of a graph can be computed using MaximumIndependentSet[g] in the *Mathematica* add-on package DiscreteMath`Combinatorica` (which can be loaded with the command < <DiscreteMath`).
An independent set of edges can be defined similarly (Skiena 1990, p. 219). Gallai (1959) showed that the size of the minimum EDGE COVER plus the side of the maximum number of independent edges equals the number of vertices of a graph.

See also CLIQUE, DISJOINT SETS, EDGE COVER, EMPTY SET, INDEPENDENCE NUMBER, INTERSECTION, VENN DIAGRAM, VERTEX COVER

Skiena, S. "Maximum Independent Set" §5.6.3 in *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, pp. 218–19, 1990.

Independent Statistics

Two variates A and B are statistically independent IFF the CONDITIONAL PROBABILITY $P(A|B)$ of A given B satisfies

$$P(A|B) = P(A), \tag{1}$$

in which case the probability of A and B is just

$$P(A, B) = P(A \cap B) = P(A)P(B). \tag{2}$$

Similarly, n events $A_1, A_2, \ldots, A_n$ are independent IFF

$$p\left(\bigcap_{i=1}^{n} A_i\right) = \prod_{i=1}^{n} P(A_i). \tag{3}$$

Statistically independent variables are always UNCORRELATED, but the converse is not necessarily true.

See also BAYES' FORMULA, CONDITIONAL PROBABILITY, INDEPENDENT EVENTS, INDEPENDENCE COMPLEMENT THEOREM, UNCORRELATED

Independent Vertices

A set of VERTICES A of a GRAPH with EDGES V is independent if it contains no EDGES.

See also INDEPENDENCE NUMBER

Indeterminate

Not definitively or precisely determined. Certain forms of LIMITS are said to be indeterminate when merely knowing the limiting behavior of individual parts of the expression is not sufficient to actually determine the overall limit. For example, a LIMIT OF THE FORM 0/0, i.e., $\lim_{x\to 0} f(x)/g(x)$ where $\lim_{x\to 0} f(x) = \lim_{x\to 0} g(x) = 0$, is indeterminate since the value of the overall limit actually depends on the limiting behavior of the combination of the two functions (e.g. $\lim_{x\to 0} x/x = 1$, while $\lim_{x\to 0} x^2/x = 0$).

Indeterminate Problems

DIOPHANTINE EQUATION

Index

The word "index" has a very large number of completely different meanings in mathematics. Most commonly, it is used in the context of an INDEX SET, where it means a quantity which can take on a set of values and is used to designate one out of a number of possible values associated with this value. For example, the subscript i in the symbol a_i could be called the index of a.

In a RADICAL $\sqrt{x}$, the quantity n is called the index.

The word index has a special meaning in economics, where it refers to a single quantity used to quantify the "average" value of a possibly complicated set of quantities. In this context, it is sometimes called an INDEX NUMBER.

In TOPOLOGY, INDEX THEORY refers to the study of topological invariants of MANIFOLDS.

See also INDEX LOWERING, INDEX RAISING, INDEX SET, MANIFOLD, MULTIPLICATIVE ORDER, STATISTICAL INDEX

Index (Extension Field)

DEGREE (EXTENSION FIELD

Index (Modulo)

MULTIPLICATIVE ORDER

Index (Residue)

MULTIPLICATIVE ORDER

Index (Subgroup)

This entry contributed by NICOLAS BRAY

For a SUBGROUP H of a GROUP G, the index of H, denoted $(G : H)$, is the CARDINALITY of the set of LEFT COSETS of H in G (which is equal to the CARDINALITY of the set of RIGHT COSETS of H in G).

See also COSET, LAGRANGE'S GROUP THEOREM, LEFT COSET, RIGHT COSET

Index (Tensor)

See also INDEX LOWERING, INDEX RAISING

Index Law

EXPONENT LAWS

Index Lowering

The indices of a CONTRAVARIANT TENSOR A^j can be lowered, turning it into a COVARIANT TENSOR A_i, by multiplication by a so-called METRIC TENSOR, e.g.,

$$g_{ij}A^j = A_i.$$

See also CONTRAVARIANT TENSOR, COVARIANT TENSOR, INDEX RAISING, INDEX (TENSOR), TENSOR

Index Number

A STATISTIC which assigns a single number to several individual statistics in order to quantify trends. The best-known index in the United States is the consumer price index, which gives a sort of "average" value for inflation based on price changes for a group of selected products. The Dow Jones and NASDAQ indexes for the New York and American Stock Exchanges, respectively, are also index numbers.

Let p_n be the price per unit in period n, q_n be the quantity produced in period n, and $v_n \equiv p_n q_n$ be the value of the n units. Let q_a be the estimated relative importance of a product. There are several types of indices defined, among them those listed in the following table.

Index	Abbr.	Formula
BOWLEY INDEX	P_B	$\frac{1}{2}(P_L + P_P)$
FISHER INDEX	P_F	$\sqrt{P_L P_P}$
GEOMETRIC MEAN INDEX	P_G	$\left[\prod\left(\frac{p_n}{p_0}\right)^{v0}\right]^{1/\Sigma v_0}$

HARMONIC MEAN INDEX	P_H	$\frac{\Sigma p_0 q_0}{\Sigma \frac{p_0^2 q_0}{nm}}$
LASPEYRES' INDEX	P_L	$\frac{\Sigma p_n q_0}{\Sigma p_0 q_0}$
MARSHALL-EDGEWORTH INDEX	P_{ME}	$\frac{\Sigma p_n (q_0 + q_n)}{\Sigma (v_0 + v_n)}$
MITCHELL INDEX	P_M	$\frac{\Sigma p_n q_n}{\Sigma p_0 q_n}$
PAASCHE'S INDEX	P_P	$\frac{\Sigma p_n q_n}{\Sigma p_0 q_n}$
WALSH INDEX	P_W	$\frac{\Sigma \sqrt{q_0 q_n} p_n}{\Sigma \sqrt{q_0 q_a} p_n}$

See also BOWLEY INDEX, FISHER INDEX, GEOMETRIC MEAN INDEX, HARMONIC MEAN INDEX, LASPEYRES' INDEX, MARSHALL-EDGEWORTH INDEX, MITCHELL INDEX, PAASCHE'S INDEX, WALSH INDEX

Indicatrix

A spherical image of a curve. The most common indicatrix is DUPIN'S INDICATRIX.

See also DUPIN'S INDICATRIX

Indicial Equation

The RECURRENCE RELATION obtained during application of the FROBENIUS METHOD of solving a second-order ordinary differential equation. The indicial equation (also called the CHARACTERISTIC EQUATION) is obtained by noting that, by definition, the lowest order term x^k (that corresponding to $n = 0$) must have a COEFFICIENT of zero. For an example of the construction of an indicial equation, see BESSEL DIFFERENTIAL EQUATION.

1. If the two ROOTS are equal, only one solution can be obtained.
2. If the two ROOTS differ by a noninteger, two solutions can be obtained.
3. If the two ROOTS differ by an INTEGER, the larger will yield a solution. The smaller may or may not.

Induced Map

If $f:(X,A)\to(Y,B)$ is homotopic to $g:(X,A)\to(Y,B)$, then $f_*:H_n(X,A)\to H_n(Y,B)$ and $g_*:H_n(X,A)\to H_n(Y,B)$ are said to be the induced maps.

See also EILENBERG-STEENROD AXIOMS

Induced Norm

NATURAL NORM

Induced Representation

If a SUBGROUP H of G has a REPRESENTATION $\phi: H\times W\to W$, then there is a unique induced representation of G on a VECTOR SPACE V. The original space W is contained in V, and in fact,

$$V=\oplus_{\sigma\in G/H}\,\sigma W,$$

where σW is a copy of W. The induced representation on V is denoted Ind_H^G.

Alternatively, the induced representation is the $\mathbb{C}G$-MODULE

$$\mathrm{Ind}_H^G \simeq \mathbb{C}G\otimes_{\mathbb{C}H} W. \tag{1}$$

Also, it can be viewed as W-valued functions on G which commute with the H action.

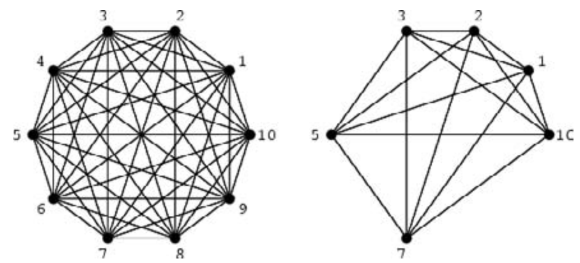
$$\mathrm{Ind}_H^G \simeq \{f: G\to W : hf(g)=f(hg)\}. \tag{2}$$

The induced representation is also determined by its UNIVERSAL PROPERTY:

$$\mathrm{Hom}_H(W,\mathrm{Res}\ U)=\mathrm{Hom}_G(\mathrm{Ind}\ W, U), \tag{3}$$

where U is any representation of G. Also, the induced representation satisfies the following formulas.

1. $\mathrm{Ind}\oplus W_i=\otimes\,\mathrm{Ind}\ W_i$.
2. $\mathrm{U}\otimes\mathrm{Ind}\ W=\mathrm{Ind}(\mathrm{Res}(U)\otimes W)$ for any REPRESENTATION U.
3. $\mathrm{Ind}_H^G(W)=\mathrm{Ind}_K^G(\mathrm{Ind}_H^K\ W)$ when $H\le K\le G$.



Some of the CHARACTERS of G can be calculated from the CHARACTERS of H, as induced representations, using FROBENIUS RECIPROCITY. ARTIN'S RECIPROCITY THEOREM says that the induced representations of CYCLIC SUBGROUPS of a FINITE GROUP G generates a LATTICE of finite index in the lattice of VIRTUAL CHARACTERS. BRAUER'S THEOREM says that the virtual characters are generated by the induced representations from p-ELEMENTARY SUBGROUPS.

Induced Subgraph

An induced subgraph is a subset of the edges of a GRAPH G together with any edges whose endpoints are both in this subset. The figure above illustrates the subgraph induced on the COMPLETE GRAPH K_5 by the vertex subset $\{1,2,3,5,7,10\}$. An induced subgraph that is a COMPLETE GRAPH is called a CLIQUE. Any induced subgraph of a COMPLETE GRAPH forms a CLIQUE. An induced subgraph can be computed using `InduceSubgraph[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

See also CLIQUE, SUBGRAPH

Inequality

A mathematical statement that one quantity is greater than or less than another. "a is less than b" is denoted $a < b$, and "a is greater than b" is denoted $a > b$. "a is less than or equal to b" is denoted $a \leq b$, and "a is greater than or equal to b" is denoted $a \geq b$. The symbols $a \ll b$ and $a \gg b$ are used to denote "a is much less than b" and "a is much greater than b," respectively.

Solutions to the inequality $|x-a| < b$ consist of the set $\{x : a-b < x-a+b\}$, or equivalently $\{x : a-b < x < a+b\}$. Solutions to the inequality $|x-a| > b$ consist of the set $\{x : x-a > b\} \cup \{x : x-a < -b\}$. If a and b are both POSITIVE or both NEGATIVE and $a < b$, then $1/a > 1/b$. The portions of the xy-plane satisfying a number of specific inequalities are illustrated above.

In *Mathematica* 4.0, the command `InequalityInstance[ineqs, vars]` can be used to find a real solution of the system of real equations and inequalities *ineqs* in the variables *vars* or return the EMPTY SET if no such solution exists. Solution of inequalities can be performed using `[ineqs, vars]`, in the *Mathematica* add-on package `Algebra'InequalitySolve'` (which can be loaded with the command `<<Algebra'`) or directly using `CylindricalAlgebraicDecomposition[ineqs, vars]`.

Inf

INFIMUM, INFIMUM LIMIT

Infimum

Portions of this entry contributed by JEROME R. BREITENBACH

The infimum is the greatest lower bound of a SET S, defined as a quantity m such that no member of the SET is less than m, but if ϵ is any POSITIVE quantity, however small, there is always one member that is less than $m+\epsilon$ (Jeffreys and Jeffreys 1988). When it exists (which is not required by this definition, e.g., $\mathbb{R}$ does not exist), the infimum is denoted $\inf S$ or $\inf_{x\in S} x$. The infimum can be computed using the *Mathematica* 4.0 command `Infimum[`*f*, *constr*, *vars*`]`.

More formally, the infimum $\inf S$ for S a (nonempty) SUBSET of the extended reals $\overline{\mathbb{R}} = \mathbb{R} \cup \{\pm\infty\}$ is the largest value $y \in \overline{\mathbb{R}}$ such that for all $x \in S$ we have $x \geq y$. Using this definition, inf$S$ *always* exists and, in particular, $\mathbb{R} = -\infty$.

Whenever an infimum exists, its value is unique.

Infimum Limit

Given a sequence of real numbers a_n, the infimum limit, also called the lower limit but more often simply pronounced 'lim-inf' and written liminf is the limit of

$$A_n = \inf_{k>n} a_k$$

as $n \to \infty$. Note that by definition, A_n is nondecreasing, and so either has a limit or tends to ∞. For example, suppose $a_n = (-1)^n/n$, then for n odd, $A_n = -1/n$, and for n even, $A_n = -1/(n+1)$. Another example is $a_n = \sin n$, in which case A_n is a constant sequence $A_n = -1$.

When $\limsup a_n = \liminf a_n$, the sequence converges to the real number

$$\lim a_n = \limsup a_n = \liminf a_n.$$

Otherwise, the sequence does not converge.

See also INFIMUM, LIMIT, LOWER LIMIT, SUPREMUM

Infinary Divisor

p^x is an infinary divisor of p^y (with $y>0$) if $p^x|_{y-1}p^y$. This generalizes the concept of the K-ARY DIVISOR.

See also INFINARY PERFECT NUMBER, K-ARY DIVISOR

Infinite

Greater than any assignable quantity of the sort in question. In mathematics, the concept of the infinite is made more precise through the notion of an INFINITE SET.

See also COUNTABLE SET, COUNTABLY INFINITE, FINITE, INFINITE SET, INFINITESIMAL, INFINITY

Infinite Group

A group having an infinite number of elements. Some infinite groups, such as the integers or rationals, are not CONTINUOUS GROUPS.

See also CONTINUOUS GROUP, FINITE GROUP

Infinite Product

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A PRODUCT involving an INFINITE number of terms. Such products can converge. In fact, for POSITIVE a_n, the PRODUCT $\prod_{n=1}^{\infty} a_n$ converges to a NONZERO number IFF $\Sigma_{n=1}^{\infty} \ln a_n$ converges.

Infinite products can be used to define the COSINE

$$\cos x = \prod_{n=1}^{\infty} \left[1 - \frac{4x^2}{\pi^2(2n-1)^2}\right], \tag{1}$$

GAMMA FUNCTION

$$\Gamma(z) = \left[z e^{\gamma z} \prod_{r=1}^{\infty} \left(1 + \frac{z}{r}\right) e^{-z/r} \right]^{-1}, \tag{2}$$

SINE, and SINC FUNCTION. They also appear in the POLYGON CIRCUMSCRIBING CONSTANT

$$k = \prod_{n=3}^{\infty} \frac{1}{\cos\left(\frac{\pi}{n}\right)}. \tag{3}$$

An interesting infinite product formula due to Euler which relates π and the nth PRIME p_n is

$$\pi = \frac{2}{\Pi_{i=n}^{\infty}\left[1 + \frac{\sin\left(\frac{1}{2}\pi p_n\right)}{p_n}\right]} \tag{4}$$

$$= \frac{2}{\Pi_{i=n}^{\infty}\left[1 + \frac{(-1)(p_n-1)/2}{p_n}\right]} \tag{5}$$

(Blatner 1997). KNAR'S FORMULA gives a functional equation for the GAMMA FUNCTION $\Gamma(x)$ in terms of the infinite product

$$\Gamma(1+v) = 2^{2v} \prod_{m=1}^{\infty} \left[\pi^{-1/2}\Gamma\left(\tfrac{1}{2} + 2^{-m}v\right)\right]. \tag{6}$$

The class of products

$$\prod_{n=2}^{\infty} \frac{n^2-1}{n^2+1} = \pi \operatorname{csch} \pi \tag{7}$$

$$\prod_{n=2}^{\infty} \frac{n^3-1}{n^3+1} = \tfrac{2}{3} \tag{8}$$

$$\prod_{n=2}^{\infty} \frac{n^4-1}{n^4+1} = -\tfrac{1}{2}\pi \sinh \pi \csc\left[(-1)^{1/4}\pi\right] \csc\left[(-1)^{3/4}\pi\right], \tag{9}$$

the first of which is given in Borwein and Corless (1999), can be done analytically.

The first few products

$$\prod_{k=1}^{\infty} \frac{(1+k^{-1})^2}{1+2k^{-1}} = 2 \tag{10}$$

$$\prod_{k=1}^{\infty} \frac{(1+k^{-1}+k^{-2})^2}{1+2k^{-1}+3k^{-2}} = \frac{3\sqrt{2}\cosh^2\left(\frac{1}{2}\pi\sqrt{3}\right)\operatorname{csch}(\pi\sqrt{2})}{\pi} \tag{11}$$

$$\prod_{k=1}^{\infty} \frac{(1+k^{-1}+k^{-2}+k^{-3})2}{1+2k^{-1}+3k^{-2}+4k^{-3}} = \frac{\sinh^2 \pi \Pi_{i=1}^{3}\Gamma(x_i)}{\pi^2}, \tag{12}$$

$$\prod_{k=1}^{\infty} \frac{(1+k^{-1}+k^{-2}+k^{-3}+k^{-4})^2}{1+2k^{-1}+3k^{-2}+4k^{-3}+5k^{-4}} = \prod_{i=1}^{4} \frac{\Gamma(y_i)}{\Gamma(z_i)} \tag{13}$$

where x_i, y_i, and z_i are the roots of

$$x^3 - 5x^2 + 10x - 10 = 0 \tag{14}$$

$$y^4 - 6y^3 + 15y^2 - 20y + 15 = 0, \tag{15}$$

and

$$z^4 - 5z^3 + 10z^2 - 10z + 5 = 0, \tag{16}$$

respectively, can also be done analytically. Note that (15) and (16) were unknown to Borwein and Corless (1999).

The product

$$\prod_{n=1}^{\infty} \left(1 + \frac{1}{n^p}\right) \tag{17}$$

has closed form expressions for small POSITIVE integral $p \geq 2$,

$$\prod_{n=1}^{\infty} \left(1 + \frac{1}{n^2}\right) = \frac{\sinh \pi}{\pi} \tag{18}$$

$$\prod_{n=1}^{\infty} \left(1 + \frac{1}{n^3}\right) = \frac{1}{\pi}\cosh\left(\tfrac{1}{2}\pi\sqrt{3}\right) \tag{19}$$

$$\prod_{n=1}^{\infty} \left(1 + \frac{1}{n^4}\right) = \frac{\cosh(\pi\sqrt{2}) - \cos(\pi\sqrt{2})}{2\pi^2} \tag{20}$$

$$\prod_{n=1}^{\infty} \left(1 + \frac{1}{n^5}\right) = \left|\Gamma\left[\exp\left(\tfrac{2}{5}\pi i\right)\right]\Gamma\left[\exp\left(\tfrac{6}{5}\pi i\right)\right]\right|^{-2} \tag{21}$$

The D-ANALOG expression

$$[\infty!]_d = \prod_{n=3}^{\infty} \left(1 - \frac{2^d}{n^d}\right) \tag{22}$$

also has closed form expressions,

$$\prod_{n=3}^{\infty}\left(1-\frac{4}{n^2}\right)=\frac{1}{6} \tag{23}$$

$$\prod_{n=3}^{\infty}\left(1-\frac{8}{n^3}\right)=\frac{\sinh(\pi\sqrt{3})}{42\pi\sqrt{3}} \tag{24}$$

$$\prod_{n=3}^{\infty}\left(1-\frac{16}{n^4}\right)=\frac{\sinh(2\pi)}{120\pi} \tag{25}$$

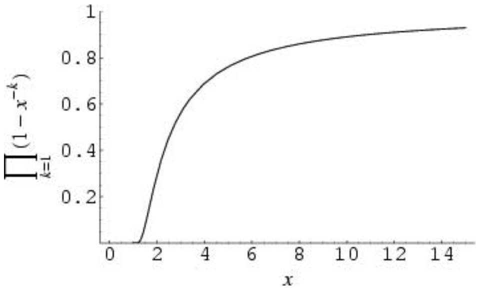
$$\prod_{n=3}^{\infty}\left(1-\frac{32}{n^5}\right)=\left|\Gamma\left[\exp\left(\tfrac{1}{5}\pi i\right)\right]\Gamma\left[2\exp\left(\tfrac{7}{5}\pi i\right)\right]\right|^{-2} \tag{26}$$

General expressions for infinite products of this type include

$$\prod_{n=1}^{\infty}\left[1-\left(\frac{z}{n}\right)^{2N}\right]=\frac{\sin(\pi z)}{\pi z^{2N-1}}\prod_{k=1}^{N-1}\left|\Gamma\left(ze^{2\pi i(k-N)/(2N)}\right)\right|^{-2} \tag{27}$$

$$\prod_{n=1}^{\infty}\left[1+\left(\frac{z}{n}\right)^{2N}\right]=\frac{1}{z^{2N}}\prod_{k=1}^{N}\left|\Gamma\left(ze^{\pi i[2(k-N)-1]/(2N)}\right)\right|^{-2} \tag{28}$$

$$\prod_{n=1}^{\infty}\left[1+\left(\frac{z}{n}\right)^{2N+1}\right]=\frac{1}{\Gamma(1-z)z^{2N}}\prod_{k=1}^{N}\left|\Gamma\left(ze^{\pi i(2(k-N)-1/(2N+1)}\right)\right|^{-2} \tag{29}$$



$$\prod_{n=1}^{\infty}\left[1+\left(\frac{z}{n}\right)^{2N+1}\right]=\frac{1}{\Gamma(1+z)z^{2N}}\prod_{k=1}^{N}\left|\Gamma\left(ze^{2\pi i(k-N-1)/2N+1}\right)\right|^{-2} \tag{30}$$

where $\Gamma(z)$ is the GAMMA FUNCTION and $|z|$ denotes the MODULUS (Kahovec). (27) and (28) can also be rewritten as

$$\prod_{n=1}^{\infty}\left[1-\left(\frac{z}{n}\right)^{2N}\right]=\frac{\sin(\pi z)}{\pi^3 z^2}\left(\frac{\sinh(\pi z)}{\pi z}\right)^{\operatorname{mod}(N+1,2)} \times\prod_{k=1}^{\lceil N/2\rceil-1}\cosh^2\left[\pi z\sin\left(\frac{k\pi}{N}\right)\right]-\cos^2\left[\pi z\cos\left(\frac{k\pi}{N}\right)\right] \tag{31}$$

$$\prod_{n=1}^{\infty}\left[1+\left(\frac{z}{n}\right)^{2N}\right]=\frac{1}{\pi^2 z^2}\left(\frac{\sinh(\pi z)}{\pi z}\right)^{\operatorname{mod}(N,2)} \times\prod_{k=1}^{\lfloor N/2\rfloor}\cosh^2\left[\pi z\sin\left(\frac{(2k-1)\pi}{2N}\right)\right]-\cos^2\left[\pi z\cos\left(\frac{(2k-1)\pi}{2N}\right)\right], \tag{32}$$

where $\lfloor x\rfloor$ is the FLOOR FUNCTION, $\lceil x\rceil$ is the CEILING FUNCTION, and $\operatorname{mod}(a,m)$ is the modulus of a (mod m) (Kahovec).

Infinite products OF THE FORM

$$\prod_{k=1}^{\infty}\left(1-\frac{1}{n^k}\right) \tag{33}$$

converge for $n\geq 2$. I am not aware of any analytic expressions, but the first few such products are numerically given by

$$\prod_{k=1}^{\infty}\left(1-\frac{1}{2^k}\right)\approx 0.28878809508660242128 \tag{34}$$

$$\prod_{k=1}^{\infty}\left(1-\frac{1}{3^k}\right)\approx 0.56012607792794894497 \tag{35}$$

$$\prod_{k=1}^{\infty}\left(1-\frac{1}{4^k}\right)\approx 0.68853753712033971546 \tag{36}$$

$$\prod_{k=1}^{\infty}\left(1-\frac{1}{5^k}\right)\approx 0.76033279587123242010. \tag{37}$$

A class of infinite products derived from the BARNES' G-FUNCTION is given by

$$\prod_{n=1}^{\infty}\left(1+\frac{z}{n}\right)^n e^{-z+z^2/(2n)}=\frac{G(z)}{(2\pi)^{\pi/2}}e^{[z(z+1)+\gamma z^2]/2}, \tag{38}$$

where γ is the EULER-MASCHERONI CONSTANT. The first few cases are

$$\prod_{n=1}^{\infty}\left(1+\frac{1}{n}\right)^n e^{1/(2n)-1}=\frac{e^{1+\gamma/2}}{\sqrt{2\pi}} \tag{39}$$

$$\prod_{n=1}^{\infty}\left(1+\frac{2}{n}\right)^n e^{4/(2n)-2}=\frac{e^{3+2\gamma}}{2\pi} \tag{40}$$

$$\prod_{n=1}^{\infty}\left(1+\frac{3}{n}\right)^n e^{9/(2n)-3}=\frac{e^{6+9\gamma/2}}{(2\pi)^{3/2}} \tag{41}$$

$$\prod_{n=1}^{\infty}\left(1+\frac{4}{n}\right)^{n} e^{16/(2n)-3}=\frac{e^{10+8\gamma}}{2\pi^{2}}. \quad (42)$$

The interesting identities

$$x\prod_{n=1}^{\infty}\frac{(1-x^{2n})^{8}}{(1-x^{2n-1})^{8}}=\sum_{n=1}^{\infty}2^{3b(n)}\sigma_{3}(\mathrm{Od}(n))x^{n} \quad (43)$$

(Ewell 1995, 1999), where $b(n)$ is the exponent of the exact power of 2 dividing n, $\mathrm{Od}(n)$ is the ODD PART of n, $\sigma_k(n)$ is the DIVISOR FUNCTION of n, and $r_k(n)$ is the SUM OF SQUARES FUNCTION, and

$$\prod_{n=1}^{\infty}(1+x^{2n-1})^{8}=\prod_{n=1}^{\infty}(1-x^{2n-1})^{8}+16x\prod_{n=1}^{\infty}(1+x^{2n})^{8} \quad (44)$$

(Ewell 1998, 1999) arise is connection with the TAU FUNCTION.

Infinite Series

A SERIES with an INFINITE number of terms is called an infinite series. A (possibly infinite) series for which the ratio of each two consecutive terms a_{k+1}/a_k is a constant function of the summation index k. The more general case of the ratio a RATIONAL FUNCTION of the summation index k produces a series called a HYPERGEOMETRIC SERIES.

A particular infinite series identity is given by

$$\sum_{k=1,3,5,\ldots}^{\infty}\frac{e^{-kx}\sin(ky)}{k}=\frac{1}{2}\tan^{-1}\left(\frac{\sin y}{\sinh x}\right) \quad (1)$$

for $x>0$. Apostol (1997, p. 25) gives the analytic sum

$$\sum_{n=1,3,5,\ldots}^{\infty}\frac{n^{4k+1}}{1+e^{n\pi}}=\frac{2^{4k+1}-1}{8k+4}B_{4k+2}, \quad (2)$$

where B_k is a BERNOULLI NUMBER.

Infinite series of the following type can also be computed analytically,

$$\left(\sum_{k=0}^{\infty}x^{k}\right)^{p}=(1-x)^{-p} \quad (3)$$

$$=\frac{1}{(p-1)!}\sum_{n=0}^{\infty}\frac{(n+p-1)!}{n!}x^{n}. \quad (4)$$

$$=\frac{1}{(p-1)!}\sum_{n=0}^{\infty}(n+1)_{p-1}x^{n}, \quad (5)$$

where $(n)_p$ is a POCHHAMMER SYMBOL.

An infinite series of the following form can be done in closed form.

$$\sum_{k=1}^{\infty}\frac{1}{[1+k^{2}\pi^{2}]^{n}}=\frac{p_{n}(e)}{2^{n+1}n!(e^{2}-1)^{n}}, \quad (6)$$

where $P_n(e^2)$ is an nth order polynomial in e^2. The first few polynomials are

$$P_1=1$$

$$P_2=-e^4+8e^2-3$$

$$P_3=-5e^6+41e^4-31e^2+11$$

$$P_4=-33e^8+286e^6-344e^4+250e^2-63.$$

The related infinite series can also be done in closed form.

$$\sum_{k=1}^{\infty} \frac{1}{\left[1+\left(k+\frac{1}{2}\right)^2 \pi^2\right]^n} = \frac{Q_n(e)}{2^{n+1} n! (e^2+1)^n} - \frac{4^n}{(4+\pi^2)^n}, \tag{7}$$

where $Q_n(e^2)$ is an nth order polynomial in e^2. The first few polynomials are

$$Q_1 = e^2 - 1$$

$$Q_2 = e^4 - 4e^2 - 1$$

$$Q_3 = 3e^6 - 17e^4 - 7e^2 - 3$$

$$Q_4 = 15e^8 - 94e^6 - 56e^4 - 58e^2 - 15$$

$$Q_5 = 105e^{10} - 657e^8 - 578e^6 - 982e^4 - 503 - 105.$$

Infinite Set

A SET of S elements is said to be infinite if the elements of a PROPER SUBSET S' can be put into ONE-TO-ONE correspondence with the elements of S. An infinite set whose elements can be put into a ONE-TO-ONE correspondence with the set of INTEGERS is said to be COUNTABLY INFINITE; otherwise, it is called UNCOUNTABLY INFINITE.

Infinite Sum

An infinite sum identity is given by

$$z^4 - 5z^3 + 10z^2 - 10z + 5 = 0,$$

for $\prod_{n=1}^{\infty}\left(1+\frac{1}{n^p}\right)$.

See also INFINITE PRODUCT

Infinitesimal

A quantity which yields 0 after the application of some LIMITING process. The understanding of infinitesimals was a major roadblock to the acceptance of CALCULUS and its placement on a firm mathematical foundation.

See also INFINITE, INFINITY, NONSTANDARD ANALYSIS

References

Bell, J. L. *A Primer of Infinitesimal Analysis.* Cambridge, England: Cambridge University Press, 1998.

Infinitesimal Analysis

An archaic term for CALCULUS.

Infinitesimal Matrix Change

Let B, A, and e be square matrices with e small, and define

$$\mathsf{B} \equiv \mathsf{A}(\mathsf{I}+\mathsf{e}), \tag{1}$$

where I is the IDENTITY MATRIX. Then the inverse of B is approximately

$$\mathsf{B}\mathsf{B}^{-1} = (\mathsf{I}-\mathsf{e})\mathsf{A}^{-1}. \tag{2}$$

This can be seen by multiplying

$$\begin{aligned}\mathsf{B}\mathsf{B}^{-1} &= (\mathsf{A}+\mathsf{A}\mathsf{e})(\mathsf{A}^{-1}-\mathsf{e}\mathsf{A}^{-1})\\ &= \mathsf{A}\mathsf{A}^{-1} - \mathsf{A}\mathsf{e}\mathsf{A}^{-1} + \mathsf{A}\mathsf{e}\mathsf{A}^{-1} - \mathsf{A}\mathsf{e}^2\mathsf{A}^{-1}\\ &= \mathsf{I} - \mathsf{A}\mathsf{e}^2\mathsf{A}^{-1} \approx 1.\end{aligned} \tag{3}$$

Note that if we instead let $\mathsf{B}' \equiv \mathsf{A}+\mathsf{e}$, and look for an inverse OF THE FORM $\mathsf{B}'^{-1} = \mathsf{A}^{-1} + \mathsf{C}$, we obtain

$$\begin{aligned}\mathsf{B}\mathsf{B}'^{-1} &= (\mathsf{A}+\mathsf{e})(\mathsf{A}^{-1}+\mathsf{C}) = \mathsf{A}\mathsf{A}^{-1} + \mathsf{A}\mathsf{C} + \mathsf{e}\mathsf{A}^{-1} + \mathsf{e}\mathsf{C}\\ &= \mathsf{I} + \mathsf{A}\mathsf{C} + \mathsf{e}(\mathsf{C}+\mathsf{A}^{-1}) \equiv \mathsf{I}.\end{aligned} \tag{4}$$

In order to eliminate the e term, we require $\mathsf{C} = -\mathsf{A}^{-1}$. However, then $\mathsf{A}\mathsf{C} = -\mathsf{I}$, so $\mathsf{B}\mathsf{B}^{-1} = 0$ so there can be no inverse of this form.

The exact inverse of B' can be found as follows.

$$\mathsf{B}' = \mathsf{A}(\mathsf{I}+\mathsf{e}) = \mathsf{A}(\mathsf{I}+\mathsf{A}^{-1}\mathsf{e}), \tag{5}$$

so

$$B'^{-1} = [A(I + A^{-1}e)]^{-1}. \quad (6)$$

Using a general MATRIX INVERSE identity then gives

$$B'^{-1} = \left(I + A^{-1}e\right)^{-1}A^{-1}. \quad (7)$$

Infinitesimal Rotation

An infinitesimal transformation of a VECTOR $\mathbf{r}$ is given by

$$r' = (I + e)r, \quad (1)$$

where the MATRIX e is infinitesimal and I is the IDENTITY MATRIX. (Note that the infinitesimal transformation may not correspond to an inversion, since inversion is a discontinuous process.) The COMMUTATIVITY of infinitesimal transformations e_1 and e_2 is established by the equivalence of

$$(I + e_1)(I + e_2) = I^2 + e_1 I + I e_2 + e_1 e_2 \approx I + e_1 + e_2 \quad (2)$$

$$(I + e_2)(I + e_1) = I^2 + e_2 I + I e_1 + e_2 e_1 \approx I + e_2 + e_1. \quad (3)$$

Now let

$$A \equiv I + e, \quad (4)$$

The inverse A^{-1} is then $I - e$, since

$$AA^{-1} = (I + e)(I - e) = I^2 - e^2 \approx I. \quad (5)$$

Since we are defining our infinitesimal transformation to be a rotation, ORTHOGONALITY of ROTATION MATRICES requires that

$$A^T = A^{-1}, \quad (6)$$

but

$$A^{-1} = I - e \quad (7)$$

$$(I + e)^T = I^T + e^T = I + e^T, \quad (8)$$

so $e = -e^T$ and the infinitesimal rotation is ANTISYMMETRIC. It must therefore have a MATRIX OF THE FORM

$$e = \begin{bmatrix} 0 & d\Omega_3 & -d\Omega_2 \\ -d\Omega_3 & 0 & d\Omega_1 \\ d\Omega_2 & -d\Omega_1 & 0 \end{bmatrix}. \quad (9)$$

The differential change in a vector $\mathbf{r}$ upon application of the ROTATION MATRIX is then

$$d\mathbf{r} \equiv \mathbf{r}' - \mathbf{r} = (I + e)\mathbf{r} - \mathbf{r} = e\mathbf{r}. \quad (10)$$

Writing in MATRIX form,

$$d\mathbf{r} = \begin{bmatrix} x \\ y \\ z \end{bmatrix} \begin{bmatrix} 0 & d\Omega_3 & -d\Omega_2 \\ -d\Omega_3 & 0 & d\Omega_1 \\ d\Omega_2 & -d\Omega_1 & 0 \end{bmatrix}$$

$$= \begin{bmatrix} y\ d\Omega_3 - z\ d\Omega_2 \\ z\ d\Omega_1 - x\ d\Omega_3 \\ x\ d\Omega_2 - y\ d\Omega_1 \end{bmatrix} \quad (11)$$

$$= (y\ d\Omega_3 - z\ d\Omega_2)\hat{\mathbf{x}} + (z\ d\Omega_1 - x\ d\Omega_3)\hat{\mathbf{y}}$$

$$+ (x\ d\Omega_2 - y d\Omega_1)\hat{\mathbf{z}} = \mathbf{r} \times d\Omega. \quad (12)$$

Therefore,

$$\left(\frac{d\mathbf{r}}{dt}\right)_{\text{rotation, body}} = \mathbf{r} \times \frac{d\Omega}{dt} = \mathbf{r} \times \omega, \quad (13)$$

where

$$\omega \equiv \frac{d\Omega}{dt} = \hat{\mathbf{n}}\frac{d\phi}{dt}. \quad (14)$$

The total rotation observed in the stationary frame will be a sum of the rotational velocity and the velocity in the rotating frame. However, note that an observer in the stationary frame will see a velocity opposite in direction to that of the observer in the frame of the rotating body, so

$$\left(\frac{d\mathbf{r}}{dt}\right)_{\text{space}} = \left(\frac{d\mathbf{r}}{dt}\right)_{\text{body}} + \omega \times \mathbf{r}. \quad (15)$$

This can be written as an operator equation, known as the ROTATION OPERATOR, defined as

$$\left(\frac{d}{dt}\right)_{\text{space}} = \left(\frac{d}{dt}\right)_{\text{body}} + \omega \times . \quad (16)$$

See also ACCELERATION, EULER ANGLES, ROTATION, ROTATION MATRIX, ROTATION OPERATOR

Infinitive Sequence

A sequence $\{x_n\}$ is called an infinitive sequence if, for every i, $x_n = i$ for infinitely many n. Write $a(i,j)$ for the jth index n for which $x_n = i$. Then as i and j range through N, the array $A = a(i,j)$, called the associative array of x, ranges through all of N.

Infinitude of Primes

EUCLID'S THEOREMS

Infinity

An unbounded number greater than every REAL NUMBER, most often denoted as ∞. The symbol ∞ had been used as an alternative to M (1,000) in ROMAN NUMERALS until 1655, when John Wallis suggested it be used instead for infinity.

Infinity is a very tricky concept to work with, as evidenced by some of the counterintuitive results which follow from Georg Cantor's treatment of

INFINITE SETS. Informally, $1/\infty = 0$, a statement which can be made rigorous using the LIMIT concept,

$$\lim_{x\to\infty} \frac{1}{x} = 0.$$

Similarly,

$$\lim_{x\to 0^+} \frac{1}{x} = \infty,$$

where the notation 0^+ indicates that the LIMIT is taken from the POSITIVE side of the REAL LINE.

Inflection Point

A point on a curve at which the SIGN of the CURVATURE (i.e., the concavity) changes. The FIRST DERIVATIVE TEST can sometimes distinguish inflection points from EXTREMA for DIFFERENTIABLE functions $f(x)$.

See also CURVATURE, DIFFERENTIABLE, EXTREMUM, FIRST DERIVATIVE TEST, STATIONARY POINT

Information Dimension

Define the "information function" to be

$$I = -\sum_{i=1}^{N} P_i(\epsilon) \ln[P_i(\epsilon)], \quad (1)$$

where $P_i(\epsilon)$ is the NATURAL MEASURE, or probability that element i is populated, normalized such that

$$\sum_{i=1}^{N} P_i(\epsilon) = 1. \quad (2)$$

The information dimension is then defined by

$$d_{\text{inf}} \equiv -\lim_{\epsilon\to 0^+} \frac{I}{\ln(\epsilon)}$$

$$= \lim_{\epsilon\to 0^+} \sum_{i=1}^{N} \frac{P_i(\epsilon)\ln[P_i(\epsilon)]}{\ln(\epsilon)}. \quad (3)$$

If every element is equally likely to be visited, then $P_i(\epsilon)$ is independent of i, and

$$\sum_{i=1}^{N} P_i(\epsilon) = NP_i(\epsilon) = 1, \quad (4)$$

so

$$P_i(\epsilon) = \frac{1}{N}, \quad (5)$$

and

$$d_{\text{inf}} = \lim_{\epsilon\to 0^+} \frac{\sum_{i=1}^{N} \frac{1}{N} \ln\left(\frac{1}{N}\right)}{\ln \epsilon}$$

$$= \lim_{\epsilon\to 0^+} \frac{\ln(N^{-1})}{\ln \epsilon} = -\lim_{\epsilon\to 0^+} \frac{\ln N}{\ln \epsilon} = d_{\text{cap}}, \quad (6)$$

where d_{cap} is the CAPACITY DIMENSION.

Initial Ordinal

An ordinal number is called an initial ordinal if every smaller ordinal has a smaller cardinality (Moore 1982, p. 248; Rubin 1967, p. 271). The ω_αs ordinal numbers are just the transfinite initial ordinals (Rubin 1967, p. 272).

This proper class can be well ordered and put into one-to-one correspondence with the ordinal numbers. For any two well ordered sets that are order isomorphic, there is only one order isomorphism between them. Let f be that isomorphism from the ordinals to the transfinite initial ordinals, then

$$\omega_\alpha = f(\alpha),$$

where $\omega_0 = \omega$.

Initial Segment

Let $(A, \leq)$ be a well ordered set. Then the set $\{a \in A : a < k\}$ for some $k \in A$ is called an initial segment of A (Rubin 1967, p. 161; Dauben 1990, pp. 196–97; Moore 1982, pp. 90–1). This term was first used by Cantor, who also proved that if $(A, \leq)$ and $(B, \leq)$ are well ordered sets that are not order isomorphic, then exactly one of the following statements is true:

1. A is order isomorphic to an initial segment of B, or
2. B is order isomorphic to an initial segment of A

(Dauben 1990, p. 198).

Initial Value Problem

An initial value problem is a problem that has its conditions specified at some time $t = t_0$. Usually, the problem is an ordinary differential equation or a partial differential equation. For example,

$$\begin{cases} \frac{\partial^2 u}{\partial t^2} - \nabla^2 u = f & \text{in } \Omega \\ u = u_0 & t = t_0 \\ u = u_1 & \text{on } \partial\Omega, \end{cases}$$

where $\partial\Omega$ denotes the boundary of Ω, is an initial value problem.

Injection

One-to-One

Injective

A map is injective when it is one-to-one, i.e., f is injective when $x \neq y$ implies $f(x) \neq f(y)$.

See also One-to-One, Surjective

Injective Patch

An injective patch is a patch such that $\mathbf{x}(u_1, v_1) = \mathbf{x}(u_2, v_2)$ implies that $u_1 = u_2$ and $v_1 = v_2$. An example of a patch which is injective but not regular is the function defined by (u^3, v^3, uv) for $u, v \in (-1, 1)$. However, if $\mathbf{x} : U \to \mathbb{R}^n$ is an injective regular patch, then $\mathbf{x}$ maps U diffeomorphically onto $\mathbf{x}(U)$.

Inradius

The radius of a TRIANGLE'S INCIRCLE or of a POLYHEDRON'S INSPHERE, denoted r (or sometimes ρ). For a TRIANGLE,

$$r = \frac{1}{2}\sqrt{\frac{(b+c-a)(c+a-b)(a+b-c)}{a+b+c}} \tag{1}$$

$$= \frac{\Delta}{s} \tag{2}$$

$$4R\sin\left(\tfrac{1}{2}A\right)\sin\left(\tfrac{1}{2}B\right)\sin\left(\tfrac{1}{2}C\right), \tag{3}$$

where Δ is the AREA of the TRIANGLE, a, b, and c are the side lengths, s is the SEMIPERIMETER, R is the CIRCUMRADIUS, and A, B, and C are the angles opposite sides a, b, and c (Johnson 1929, p. 189). If two triangle side lengths a and b are known, together with the inradius r, then the length of the third side c can be found by solving (1) for c, resulting in a CUBIC EQUATION.

Equation (2) can be derived easily using TRILINEAR COORDINATES. Since the INCENTER is equally spaced from all three sides, its trilinear coordinates are 1:1:1, and its exact trilinear coordinates are $r:r:r$. The ratio k of the exact trilinears to the homogeneous coordinates is given by

$$k = \frac{2\Delta}{a+b+c} = \frac{\Delta}{s}. \tag{4}$$

But since $k = r$ in this case,

$$r = k = \frac{\Delta}{s}, \tag{5}$$

Q.E.D.

Other equations involving the inradius include

$$Rr = \frac{abc}{4s} \tag{6}$$

$$\Delta^2 = rr_1r_2r_3 \tag{7}$$

$$\cos A + \cos B + \cos C = 1 + \frac{r}{R} \tag{8}$$

$$a^2 + b^2 + c^2 = 4rR + 8R^2, \tag{9}$$

where r_i are the EXRADII (Johnson 1929, pp. 189–91).

As shown in RIGHT TRIANGLE, the inradius of a RIGHT TRIANGLE side lengths a, b, and c is given by

$$r = \frac{ab}{a+b+c} \tag{10}$$

$$= \sqrt{\tfrac{1}{2}(c-a)(c-b)} \tag{11}$$

$$= \tfrac{1}{2}(a+b-c), \tag{12}$$

where c is the HYPOTENUSE.

Let d be the distance between inradius r and CIRCUMRADIUS R, $d = \overline{rR}$. Then

$$R^2 - d^2 = 2Rr \tag{13}$$

$$\frac{1}{R-d}+\frac{1}{R+d}=\frac{1}{r} \tag{14}$$

(Mackay 1886–7; Casey 1888, pp. 74–5). These and many other identities are given in Johnson (1929, pp. 186–90).

For a PLATONIC SOLID or ARCHIMEDEAN SOLID, the inradius of the solid is also the inradius of the DUAL POLYHEDRON. Expressing the MIDRADIUS ρ and CIRCUMRADIUS R in terms of the midradius gives

$$r=\frac{2}{\sqrt{\rho^2+\frac{1}{4}a^2}} \tag{15}$$

$$r=\frac{R^2-\frac{1}{4}a^2}{R} \tag{16}$$

for an ARCHIMEDEAN SOLID.

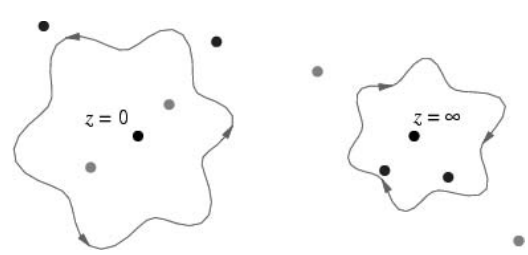
Inside-Outside Theorem



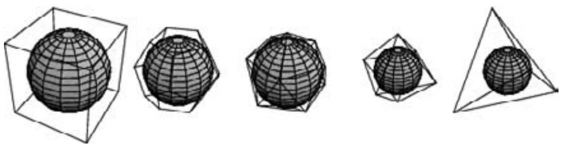
Let $P(z)$ and $Q(z)$ be UNIVARIATE POLYNOMIALS in a complex variable z, and let the DEGREES of P and Q satisfy $\deg(Q) \geq \deg(P+2)$. Then

$$\int_\gamma \frac{P(z)}{Q(z)}dz=2\pi i\sum_{a_i\in A}\operatorname*{Res}_{z=a_i}\frac{P(z)}{Q(z)} \tag{1}$$

$$=-2\pi i\sum_{b_i\in B}\operatorname*{Res}_{z=b_i}\frac{P(z)}{Q(z)}, \tag{2}$$

where γ is a simple closed clockwise-oriented CONTOUR, A is the set of ROOTS of Q inside of γ, and B is the set of ROOTS of Q outside of γ.

The first equality is an instance of the RESIDUE THEOREM. On the RIEMANN SPHERE, the simple closed CONTOUR γ splits the sphere into two regions. After the change of variables $w=1/z$, the point zero is mapped to infinity and vice versa. What was the "inside" of γ becomes the outside of γ in the new coordinate. The second equality is the RESIDUE THEOREM applied to the MEROMORPHIC ONE-FORM $a=P/Q\,dz$ in the coordinate w, with a minus sign because γ travels clockwise after the coordinate change. The hypothesis on the degrees of P and Q ensure that α does not have a POLE at $z=\infty$.



The above diagram shows two different points of view of the contour γ and the poles of the MEROMORPHIC ONE-FORM $P/Q\,dz$ on the RIEMANN SPHERE. The usual point of view is centered at $z=0$, but the role of inside and outside is switched from the point of view of $z=\infty$. The poles inside are labeled blue and outside are green.

The theorem also follows from taking the CONTOUR INTEGRAL at infinity, i.e., a circle of large radius R. The hypothesis on the degree says that this integral tends to zero. Hence it must actually be zero, because at some point the circle contains all of the poles of

P/Q. This is a special case of the fact that on a COMPACT RIEMANN SURFACE, in this case the RIEMANN SPHERE, the sum of the RESIDUES of a MEROMORPHIC ONE-FORM is zero.

Instrument Function

The finite FOURIER COSINE TRANSFORM of an APODIZATION FUNCTION, also known as an APPARATUS FUNCTION. The instrument function $I(x)$ corresponding to a given APODIZATION FUNCTION $A(x)$ is then given by

$$I(k) = \int_{-a}^{a} \cos(2\pi kx) A(x) dx.$$

See also APODIZATION FUNCTION, FOURIER COSINE TRANSFORM

Insufficient Reason Principle

A principle, also called the indifference principle, that was first enunciated by Johann Bernoulli. The insufficient reason principle states that, if we are ignorant of the ways an event can occur and therefore have no reason to believe that one way will occur preferentially to another, it will occur equally likely in any way.

Int

INTEGER PART

Integer

One of the numbers ..., -2, -1, 0, 1, 2, ... The SET of INTEGERS forms a RING which is denoted $\mathbb{Z}$. A given INTEGER n may be NEGATIVE ($a \equiv \mathbb{Z}^-$), NONNEGATIVE ($n \in \mathbb{Z}^*$), ZERO ($n = 0$), or POSITIVE ($n \in \mathbb{Z}^+ = \mathbb{N}$). The set of integers is denoted `Integers` in *Mathematica*, and a number x can be tested to see if it is an integer using the command `Element[`x, Integers]. Numbers that are integers are sometimes described as "integral" (instead of integer-valued), but this practice may lead to unnecessary confusions with the INTEGRALS of INTEGRAL CALCULUS.

The RING $\mathbb{Z}$ of integers has CARDINALITY of ALEPH-0. The GENERATING FUNCTION for the NONNEGATIVE INTEGERS is

$$f(x) = \frac{x}{(1-x)^2} = x + 2x^2 + 3x^3 + 4x^4 + \ldots.$$

There are several symbols used to perform operations having to do with conversion between REAL NUMBERS and integers. The symbol $\lfloor x \rfloor$ ("FLOOR x") means "the largest integer not greater than x," i.e., `int(x)` in computer parlance. The symbol $[x]$ means "the nearest integer to x" (NINT), i.e., `nint(x)` in computer parlance. The symbol $\lceil x \rceil$ ("CEILING x") means the smallest integer not smaller x," or `-int(-x)`, where `int(x)` is the INTEGER PART of x.

The German mathematician and logician Kronecker vociferously opposed the work of Georg Cantor on infinite sets and summarized his view that ARITHMETIC and ANALYSIS should be based on whole numbers only by saying, "God made the natural numbers; all else is the work of man" (Bell 1986, p. 477).

EULER BRICK

Integer Division

DIVISION in which the fractional part (remainder) is discarded is called integer division and is sometimes denoted \. Integer division can be defined as $a \backslash b \equiv \lfloor a/b \rfloor$ where "/" denotes normal division and $\lfloor x \rfloor$ is the FLOOR FUNCTION. For example,

$$10/3 = 3 + 1/3$$
$$10\backslash 3 = 3.$$

Integer Exponent
GREATEST DIVIDING EXPONENT

Integer Factorization
PRIME FACTORIZATION

Integer Function
A FUNCTION defined for all positive integers, sometimes also called an "arithmetical function" (Nagell 1951, p. 26).

See also COMPLEX MATRIX, REAL MATRIX

References

Nagell, T. "Arithmetical Functions." §9 in *Introduction to Number Theory.* New York: Wiley, pp. 26–9, 1951.

Integer Matrix
A MATRIX whose entries are all integers. Special cases which arise frequently are those having only $(1, -1)$ as entries (e.g., HADAMARD MATRIX), BINARY MATRICES having only $(0, 1)$ as entries (e.g., ADJACENCY MATRIX, FROBENIUS-KÖNIG THEOREM, GALE-RYSER THEOREM, HADAMARD'S MAXIMUM DETERMINANT PROBLEM, HARD SQUARE ENTROPY CONSTANT, IDENTITY MATRIX, INCIDENCE MATRIX, LAM'S PROBLEM), and those having $(-1, 0, 1)$ as entries (e.g., ALTERNATING SIGN MATRIX, C-MATRIX).

The ZERO MATRIX could be considered a degenerate case of an integer matrix.

See also ALTERNATING SIGN MATRIX, (-1,0,1)-MATRIX, (-1,1)-MATRIX, (0,1)-MATRIX, COMPLEX MATRIX, FROBENIUS-KÖNIG THEOREM, GALE-RYSER THEOREM, C-MATRIX, FIFTEEN THEOREM, GALE-RYSER THEOREM, HADAMARD'S MAXIMUM DETERMINANT PROBLEM, HADAMARD MATRIX, HAFNER-SARNAK-MCCURLEY CONSTANT, HARD SQUARE ENTROPY CONSTANT, IDENTITY MATRIX, INCIDENCE MATRIX, INTEGER-MATRIX FORM, INTERSPERSION, LAM'S PROBLEM, MORTAL, MORTALITY PROBLEM, REAL MATRIX, SMITH NORMAL FORM, SPECIAL MATRIX, UNIT MATRIX, ZERO MATRIX

Integer-Matrix Form
Let $Q(x) \equiv Q(x) = Q(x_1, x_2, \ldots, x_n)$ be an integer-valued n-ary QUADRATIC FORM, i.e., a POLYNOMIAL with integer COEFFICIENTS which satisfies $Q(x) > 0$ for REAL $x \neq 0$. Then $Q(x)$ can be represented by

$$Q(x) = \mathbf{x}^{\mathrm{T}} \mathsf{A} \mathbf{x},$$

where

$$\mathsf{A} = \frac{1}{2} \frac{\partial^2 Q(x)}{\partial x_i \partial x_j}$$

is a POSITIVE SYMMETRIC MATRIX (Duke 1997). If A has POSITIVE entries, then $Q(x)$ is called an integer-matrix form. Conway *et al.* (1997) have proven that, if a POSITIVE integer-matrix quadratic form represents each of 1, 2, 3, 5, 6, 7, 10, 14, and 15, then it represents all POSITIVE INTEGERS.

Integer Module
ABELIAN GROUP

Integer Part

The function int x gives the integer part of x. In many computer languages, the function is denoted `int(x)`. It is related to the FLOOR and CEILING FUNCTIONS $\lfloor x \rfloor$ and $\lceil x \rceil$ by

$$\operatorname{int} x = \begin{cases} \lfloor x \rfloor & \text{for } x \geq \infty \\ \lceil x \rceil & \text{for } x < 0 \end{cases}$$

The integer part function satisfies

$$\operatorname{int}(-x) = -\operatorname{int}(x)$$

and is implemented in *Mathematica* as `IntegerPart[x]`. This definition is chosen so that $\operatorname{int} x + \operatorname{frac} x = x$, where frac x is the FRACTIONAL PART. Although Spanier and Oldham (1987) use the same definition as *Mathematica*, they mention the formula only very briefly and then say it will not be used further. Graham *et al.* (1994), and perhaps most

other mathematicians, use the term "integer" part interchangeably with the FLOOR FUNCTION $\lfloor x \rfloor$.

Since usage concerning fractional part/value and integer part/value can be confusing, the following table gives a summary of names and notations used (D. W. Cantrell). Here, S&O indicates Spanier and Oldham (1987).

notation	name	S&O	Graham *et al.*	*Mathematica*
$\lfloor x \rfloor$	integer-value	Int(x)	floor or integer part	`Floor[ x]`
$\text{sgn}(x)\lfloor \lvert x \rvert \rfloor$	integer-part	Ip(x)	no name	`Integer-Part[ x]`
$x - \lfloor x \rfloor$	fractional-value	frac(x)	fractional part or $\{x\}$	no name
$\text{sgn}(x)(\lvert x \rvert - \lfloor \lvert x \rvert \rfloor)$	fractional-part	Fp(x)	no name	`Fractional-Part[ x]`

Integer Polynomial

A POLYNOMIAL OF THE FORM

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0$$

having coefficients a_i that are all integers. An integer polynomial gives integer values for all integer arguments of x (Nagell 1951, p. 73). The set of integer polynomials is denoted $\mathbb{Z}[x]$.

An integer polynomial is called primitive if the GREATEST COMMON DIVISOR $(a_0 + a_1, \ldots, a_n = 1.)$. Integer polynomials are sometimes called "integral polynomials," which is an unfortunately confusing choice of nomenclature.

See also INTEGER-REPRESENTING POLYNOMIAL, POLYNOMIAL, PRIME DIVISOR

References

Nagell, T. "Prime Divisors of Integral Polynomials" and "Divisibility of Integral Polynomials with Regard to a Prime Modulus." §25 and 29 in *Introduction to Number Theory.* New York: Wiley, pp. 73, 81–3, and 93–8, 1951.

Integer Relation

A set of REAL NUMBERS $x_1, \ldots, x_n$ is said to possess an integer relation if there exist integers a_i such that

$$a_1 x_1 + a_2 x_2 + \cdots + a_n x_n = 0,$$

with not all $a_i = 0$. For historical reasons, integer relation algorithms are sometimes called generalized Euclidean algorithms or multidimensional continued fraction algorithms.

An interesting example of such a relation is the 17-VECTOR $(1, x, x^2, \ldots, x^{16})$ with $x = 3^{1/4} - 2^{2/4}$, which has an integer relation (1, 0, 0, 0, -3860, 0, 0, 0, -666, 0, 0, 0, -20, 0, 0, 0, 1), i.e.,

$$1 - 3860x^4 - 666x^8 - 20x^{12} + x^{16} = 0.$$

This is a special case of finding the polynomial of degree $n = rs$ satisfied by $x = 3^{1/r} - 2^{1/s}$.

Integer relation algorithms can be used to solve SUBSET SUM PROBLEMS, as well as to determine if a given numerical constant is equal to a root of a univariate polynomial of degree n or less (Bailey and Ferguson 1989, Ferguson and Bailey 1992).

One of the simplest cases of an integer relation between two numbers is the one inherent in the definition of the GREATEST COMMON DIVISOR. The well-known EUCLIDEAN ALGORITHM solves this problem, as well as the more general problem of an integer relation between two real numbers, yielding either an exact relation or an infinite sequence of approximate relations (Ferguson *et al.* 1999). Although attempts were made to generalize the algorithm to $n \geq 3$ by Hermite (1850), Jacobi (1868), Poincaré (1884), Perron (1907), Brun (1919, 1920, 1957), and Szekeres (1970), all such routines were known to fail in certain cases (Ferguson and Forcade 1979, Forcade 1981, Hastad *et al.* 1989). The first successful integer relation algorithm was developed by Ferguson and Forcade (1979) (Ferguson and Bailey 1992, Ferguson *et al.* 1999).

Algorithms for finding integer relations include the FERGUSON-FORCADE ALGORITHM, HJLS ALGORITHM, LLL ALGORITHM, PSLQ ALGORITHM, PSOS ALGORITHM, and the algorithm of Lagarias and Odlyzko (1985). Perhaps the simplest (and unfortunately most inefficient) such algorithm is the GREEDY ALGORITHM.

Plouffe's "Inverse Symbolic Calculator" site includes a huge database of 54 million REAL NUMBERS which are algebraically related to fundamental mathematical constants. The FERGUSON-FORCADE ALGORITHM has shown that there are no algebraic equations of degree ≤ 8 with integer coefficients having Euclidean norms below certain bounds for e/π, $e+\pi$, $\ln \pi$, γ, e^γ, γ/e, γ/π, and $\ln \gamma$, where E is the base for the NATURAL LOGARITHM, π is PI, and γ is the EULER-MASCHERONI CONSTANT (Bailey 1988).

Constant	Bound
e/π,	6.1030×10^{14}

$e+\pi$,	2.2753×10^{14}
$\ln \pi$,	8.7697×10^{9}
γ	3.5739×10^{9}
e^{γ},	1.6176×10^{17}
γ/e,	1.8440×10^{11}
γ/π	6.5403×10^{9}
$\ln \gamma$	2.6881×10^{10}

Integer-Representing Polynomial

A polynomial that represents integers for all integer values of the variables. An INTEGER POLYNOMIAL is a special case of such a polynomial. In general, every integer representing polynomial $f(x)$ of degree n in the variable x can be written in the form

$$f(x)=A_0+A_1\binom{x}{1}+A_2\binom{x}{2}+\ldots+A_n\binom{x}{n},$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $A_0, A_1, \ldots, A_n$ are integers (Nagell 1951, p. 121).

See also INTEGER POLYNOMIAL

Integer Sequence

A SEQUENCE whose terms are INTEGERS. The most complete printed references for such sequences are Sloane (1973) and its update, Sloane and Plouffe (1995). Sloane also maintains the sequences from both works together with many additional sequences in an on-line listing. In this listing, sequences are identified by a unique 6-DIGIT A-number. Sequences appearing in Sloane and Plouffe (1995) are ordered lexicographically and identified with a 4-DIGIT M-number, and those appearing in Sloane (1973) are identified with a 4-DIGIT N-number.

Sloane's huge (and enjoyable) database is accessible by either e-mail or web browser. To look up sequences by e-mail, send a message to either mailto:sequences@research.att.com or mailto:superseeker@research.att.com containing lines OF THE FORM `lookup 5 14 42 132 ...` (note that spaces *must* be used instead of commas). To use the browser version,

point to http://www.research.att.com/~njas/sequences/eisonline.html.

Integer sequences can be analyzed by a variety techniques (Sloane and Plouffe 1995, p. 26), including the application a data compression algorithm (Bell *et al.* 1990) and computation of the DISCRETE FOURIER TRANSFORM (Loxton 1989). There are also a large number of transformations which relate integer sequences to one another, including the EULER TRANSFORM, EXPONENTIAL TRANSFORM, MÖBIUS TRANSFORM, and others (Bower, Sloane).

Integers

INTEGER

Integrable

A function for which the INTEGRAL can be computed is said to be integrable.

See also DIFFERENTIABLE, INTEGRABLE (DIFFERENTIAL IDEAL), INTEGRAL, INTEGRATION, LOCALLY INTEGRABLE

Integrable (Differential Ideal)

A DIFFERENTIAL IDEAL is an IDEAL I in the RING of smooth FORMS on a MANIFOLD M. That is, it is closed under addition, scalar multiplication, and WEDGE PRODUCT with an arbitrary form. The IDEAL I is called integrable if, whenever $\alpha \in I$, then also $d\alpha \in I$, where d is the EXTERIOR DERIVATIVE.

For example, in $\mathbb{R}^3$, the IDEAL

$$I = \{a_1 y dx + a_2 dx \wedge dy + a_3 y dx \wedge dz + a_4 dx \wedge dy \wedge dz\}, \quad (1)$$

where the a_i are arbitrary smooth functions, is an integrable differential ideal. However, if the second term were of the form $a_2 y dx \wedge dy$, then the ideal would not be integrable because it would not contain $d(ydx) = -dx \wedge dy$.

Given an integral differential ideal I on M, a SMOOTH MAP $f : X \to M$ is called integral if the PULLBACK of every form α vanishes on X, i.e., $f^*\alpha = 0$. In coordinates, an integral manifold solves a system of PARTIAL DIFFERENTIAL EQUATIONS. For example, using I above, a map $f = (f_1, f_2, f_3)$ from an OPEN SET in $\mathbb{R}^2$ is integral if

$$f_2 \frac{\partial f_1}{\partial x} = 0 \qquad (2)$$

$$f_2 \frac{\partial f_1}{\partial y} = 0 \qquad (3)$$

$$\frac{\partial f_1}{\partial x}\frac{\partial f_2}{\partial y} - \frac{\partial f_1}{\partial y}\frac{\partial f_2}{\partial x} = 0 \qquad (4)$$

$$f_2\left(\frac{\partial f_1}{\partial x}\frac{\partial f_3}{\partial y} - \frac{\partial f_1}{\partial y}\frac{\partial f_3}{\partial x}\right) = 0 \qquad (5)$$

Conversely, any system of PARTIAL DIFFERENTIAL EQUATIONS can be expressed as an integrable differential ideal on a JET BUNDLE. For instance, $\partial f/\partial x = g$ on $\mathbb{R}$ corresponds to $I = \langle df - g dx \rangle$ on $\mathbb{R}^2 = \{(x, f)\}$.

See also DIFFERENTIAL k-FORM, INTEGRABLE, JET BUNDLE, PARTIAL DIFFERENTIAL EQUATION, WEDGE PRODUCT

Integral

An integral is a mathematical object which can be interpreted as an AREA or a generalization of AREA. Integrals, together with DERIVATIVES, are the fundamental objects of CALCULUS. Other words for integral include ANTIDERIVATIVE and PRIMITIVE. The RIEMANN INTEGRAL is the simplest integral definition and the only one usually encountered in physics and elementary CALCULUS. In fact, according to Jeffreys and Jeffreys (1988, p. 29), "it appears that cases where these methods [i.e., generalizations of the Riemann integral] are applicable and Riemann's [definition of the integral] is not are too rare in physics to repay the extra difficulty." The RIEMANN INTEGRAL of the function $f(x)$ over x from a to b is written

$$\int_a^b f(x)dx. \qquad (1)$$

Every definition of an integral is based on a particular MEASURE. For instance, the RIEMANN INTEGRAL is based on JORDAN MEASURE, and the LEBESGUE INTEGRAL is based on LEBESGUE MEASURE. The process of computing an integral is called INTEGRATION (a more archaic term for INTEGRATION is QUADRATURE), and the approximate computation of an integral is termed NUMERICAL INTEGRATION.

There are two classes of (Riemann) integrals: DEFINITE INTEGRALS such as (1), which have upper and lower limits, and INDEFINITE INTEGRALS, such as

$$\int f(x)dx \qquad (2)$$

which are written without limits. The first FUNDAMENTAL THEOREM OF CALCULUS allows DEFINITE INTEGRALS to be computed in terms of INDEFINITE INTEGRALS, since if F is the INDEFINITE INTEGRAL for $f(x)$, then

$$\int_a^b f(x)dx = F(b) - F(a). \qquad (3)$$

WOLFRAM RESEARCH maintains a web site which will integrate many common (and not so common) functions. However, *Mathematica* 4.0 cannot solve some simple indefinite integrals such as

$$\int\left[\frac{d}{dx}\left(x\sqrt{\sin x}\right)\right]dx = \int\left(\frac{x\cos x}{2\sqrt{\sin x}} + \sqrt{\sin x}\right)dx \qquad (4)$$

$$\int\left[\frac{d}{dx}\operatorname{Li}_2(x\ln x)\right]dx = -\int\left[\frac{(\ln x + 1)\ln(1 - x\ln x)}{x\ln x}\right]dx, \qquad (5)$$

where $\operatorname{Li}_2(x)$ is the DILOGARITHM. Consider integrals of this form

$$I(a) = \int_0^{\pi/2} \frac{dx}{1 + (\tan x)^a}, \qquad (6)$$

can be done trivially by taking advantage of the trigonometric identity

$$\tan\left(\tfrac{1}{2}\pi - x\right) = \cot x \qquad (7)$$

Letting $z \equiv (\tan x)^a$,

$$\begin{aligned} I(a) &= \int_0^{\pi/4} \frac{dx}{1+z} + \int_{\pi/4}^{\pi/2} \frac{dx}{1+z} \\ &= \int_0^{\pi/4} \frac{dx}{1+z} + \int_0^{\pi/4} \frac{dx}{1+\frac{1}{z}} \\ &= \int_0^{\pi/4}\left(\frac{1}{1+z} + \frac{1}{1+\frac{1}{z}}\right)dx = \int_0^{\pi/4} dx \\ &= \tfrac{1}{4}\pi \end{aligned} \qquad (8)$$

However, *Mathematica* 3.0 gives an incorrect answer of $\pi^{1-2\sqrt{3}}/\left(\sqrt{3}\cdot 4^{\sqrt{3}}\right)$ to

$$I(\sqrt{3}) = \int_0^{\pi/2} \frac{dx}{1 + (\tan x)^{\sqrt{3}}} = \tfrac{1}{4}\pi, \qquad (9)$$

although integrals of this type remain unevaluated in *Mathematica* 4.0. Some care is therefore needed in the use of symbolic computer algebra packages for integration. This caveat is further illustrated by the example of the integral

$$\phi(\alpha) = \int_0^{\pi} \ln(1 - 2\alpha \cos x + \alpha^2)dx = 2\pi \ln |\alpha| \quad (10)$$

that has a simple analytic from for $|\alpha| > 1$ (Woods 1926) using the LEIBNIZ INTEGRAL RULE. However, *Mathematica* 4.0 gives a very complicated solution because it does not recognize the simple form above.

There are a wide range of methods available for NUMERICAL INTEGRATION. Good sources for such techniques include Press *et al.* (1992) and Hildebrand (1956). The most straightforward numerical integration technique uses the NEWTON-COTES FORMULAS (also called QUADRATURE FORMULAS), which approximate a function tabulated at a sequence of regularly spaced INTERVALS by various degree POLYNOMIALS. If the endpoints are tabulated, then the 2- and 3-point formulas are called the TRAPEZOIDAL RULE and SIMPSON'S RULE, respectively. The 5-point formula is called BODE'S RULE. A generalization of the TRAPEZOIDAL RULE is ROMBERG INTEGRATION, which can yield accurate results for many fewer function evaluations.

If the analytic form of a function is known (instead of its values merely being tabulated at a fixed number of points), the best numerical method of integration is called GAUSSIAN QUADRATURE. By picking the optimal ABSCISSAS at which to compute the function, Gaussian quadrature produces the most accurate approximations possible. However, given the speed of modern computers, the additional complication of the GAUSSIAN QUADRATURE formalism often makes it less desirable than the brute-force method of simply repeatedly calculating twice as many points on a regular grid until convergence is obtained. An excellent reference for GAUSSIAN QUADRATURE is Hildebrand (1956).

Here is a list of common INDEFINITE INTEGRALS:

$$\int x^r dx = \frac{x^{r+1}}{r+1} + C \quad (11)$$

$$\int \frac{dx}{x} = \ln|x| + C \quad (12)$$

$$\int a^x dx = \frac{a^x}{\ln a} + C \quad (13)$$

$$\int \sin x dx = -\cos x + C \quad (14)$$

$$\int \cos x dx = \sin x + C \quad (15)$$

$$\int \tan x dx = \ln|\sec x| + C \quad (16)$$

$$\int \csc x dx = \ln|\csc x - \cot x| + C \quad (17)$$

$$= \ln\left[\tan\left(\tfrac{1}{2}x\right)\right] + C \quad (18)$$

$$\tfrac{1}{2}\ln\left(\frac{1 - \cos x}{1 + \cos x}\right) + C \quad (19)$$

$$\int \sec x dx = \ln|\sec x + \tan x| + C \quad (20)$$

$$= \mathrm{gd}^{-1}(x) + C \quad (21)$$

$$\int \cot x dx = \ln|\sin x| + C \quad (22)$$

$$\int \sec^2 x dx = \tan x + C \quad (23)$$

$$\int \csc^2 x dx = -\cot x + C \quad (24)$$

$$\int \sec x \tan x dx = \sec x + C \quad (25)$$

$$\int \cos^{-1} x dx = x \cos^{-1} x - \sqrt{1 - x^2} + C \quad (26)$$

$$\int \sin^{-1} x dx = x \sin^{-1} x + \sqrt{1 - x^2} + C \quad (27)$$

$$\int \tan^{-1} x dx = x \tan^{-1} x - \tfrac{1}{2}\ln\left(1 + x^2\right) + C \quad (28)$$

$$\int \frac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1}\left(\frac{x}{a}\right) + C \quad (29)$$

$$\int \frac{dx}{\sqrt{a^2 - x^2}} = -\cos^{-1}\left(\frac{x}{a}\right) + C \quad (30)$$

$$\int \frac{dx}{a^2 - x^2} = \left(\frac{1}{a}\right)\tan^{-1}\left(\frac{x}{a}\right) + C \quad (31)$$

$$\int \frac{dx}{a^2 + x^2} = -\frac{1}{a}\cot^{-1}\left(\frac{x}{a}\right) + C \quad (32)$$

$$\int \frac{dx}{x\sqrt{x^2 - a^2}} = -\frac{1}{a}\sec^{-1}\left(\frac{x}{a}\right) + C \quad (33)$$

$$\int \frac{dx}{x\sqrt{x^2 - a^2}} = -\frac{1}{a}\csc^{-1}\left(\frac{x}{a}\right) + C \quad (34)$$

$$\int \sin^2(ax)dx = \frac{x}{2} - \frac{1}{4a}\sin(2ax) + C \quad (35)$$

$$\int \mathrm{sn}\, u\, du = k^{-1}\ln(\mathrm{dn}\, u - k\, \mathrm{cn}\, u) + C \quad (36)$$

$$\int \mathrm{sn}^2\, u\, du = \frac{u - E(u)}{k^2} + C \quad (37)$$

$$\int \text{cn}\, u\, du = k^{-1}\sin^{-1}(k\, \text{sn}\, u) + C \tag{38}$$

$$\int \text{dn}\, u\, du = \sin^{-1}(\text{sn}\, u) + C, \tag{39}$$

where $\sin x$ is the SINE; $\cos x$ is the COSINE; $\tan x$ is the TANGENT; $\csc x$ is the COSECANT; $\sec x$ is the SECANT; $\cot x$ is the COTANGENT; $\cos^{-1} x$ is the INVERSE COSINE; $\sin^{-1} x$ is the INVERSE SINE; $\tan^{-1} x$ is the INVERSE TANGENT; $\text{sn}\, u$, $\text{cn}\, u$, and $\text{dn}\, u$ are JACOBI ELLIPTIC FUNCTIONS; $E(u)$ is a complete ELLIPTIC INTEGRAL OF THE SECOND KIND; and $\text{gd}(x)$ is the GUDERMANNIAN FUNCTION.

To derive (16), let $u \equiv \cos x$, so $du = -\sin x dx$ and

$$\int \tan x = \int \frac{\sin u}{\cos x} dx = -\int \frac{du}{u}$$

$$= -\ln|u| + C = -\ln|\cos x| + C$$

$$= \ln|\cos x|^{-1} + C = \ln|\sec x| + C. \tag{40}$$

To derive (17), let $u \equiv \csc x - \cot x$, so $du = (-\csc x \cot x + \csc^2 x)dx$ and

$$\int \csc x dx = \int \csc x \frac{\csc x - \cot x}{\csc x - \cot x} dx$$

$$= \int \frac{\csc^2 x + \cot x \csc x}{\csc x + \cot x} dx$$

$$= \int \frac{du}{u} = \ln|u| + C$$

$$= \ln|\csc x - \cot x| + C. \tag{41}$$

To derive (20), let

$$u \equiv \sec x + \tan x, \tag{42}$$

so

$$du = (\sec x \tan x + \sec^2 x)dx \tag{43}$$

and

$$\int \sec x dx = \int \sec x \frac{\sec x + \tan x}{\sec x + \tan x} dx$$

$$= \int \frac{\sec^2 x + \sec x \tan x}{\sec x + \tan x} dx$$

$$= \int \frac{du}{u} = \ln|u| + C$$

$$= \ln|\sec x + \tan x| + C. \tag{44}$$

To derive (22), let $u \equiv \sin x$, so $du = \cos x dx$ and

$$\int \cot x dx = \int \frac{\cos x}{\sin x} dx = \int \frac{du}{u}$$

$$= \ln|u| + C = \ln|\sin x| + C. \tag{45}$$

Integral identities include

$$\frac{dx}{dy} = \frac{1}{\frac{dy}{dx}} \tag{46}$$

$$\frac{d^2x}{dy^2} = -\frac{d^2y}{dx^2}\left(\frac{dy}{dx}\right)^{-3} \tag{47}$$

$$\frac{d^3x}{dy^3} = \left[3\left(\frac{d^2y}{dx^2}\right)^2 - \frac{d^3y}{dx^3}\frac{dy}{dx}\right]\left(\frac{dy}{dx}\right)^{-5} \tag{48}$$

Differentiating integrals leads to some useful and powerful identities, for instance

$$\frac{d}{dx}\int_a^x f(x')dx' = f(x), \tag{49}$$

which is the first FUNDAMENTAL THEOREM OF CALCULUS. Other derivative-integral identities include

$$\frac{d}{dx}\int_x^b f(x')dx' = -f(x), \tag{50}$$

the LEIBNIZ INTEGRAL RULE

$$\frac{d}{dx}\int_a^b f(x,t)dt = \int_a^b \frac{\partial}{\partial x} f(x,t)dt \tag{51}$$

(Kaplan 1992, p. 275), and its generalization

$$\frac{d}{dx}\int_{u(x)}^{v(x)} f(x,t)dt$$

$$= v'(x)f(x, v(x)) - u'f(x, u(x)) + \int_{u(x)}^{v(x)} \frac{\partial}{\partial x} f(x,t)dt \tag{52}$$

(Leibniz 1992, p. 258). If $f(x,t)$ is singular or INFINITE, then

$$\frac{d}{dx}\int_a^x f(x,t)dx$$

$$= \frac{1}{x-a}\int_a^x \left[(x-a)\frac{\partial f}{\partial x} + (t-a)\frac{\partial f}{\partial x} + f\right]dt \tag{53}$$

Other integral identities include

$$\int_0^x dt_n \int_0^{t_n} dt_{n-1} \cdots \int_0^{t_3} dt_2 \int_0^{t_2} f(t_1)dt_1$$

$$= \frac{1}{(n-1)!}\int_0^x (x-t)^{n-1} f(t)dt \tag{54}$$

$$\frac{\partial}{\partial x_k}(x_j J_k) = \delta_{jk} J_k + x_j \frac{\partial}{\partial x_k} J_k = \mathbf{J} + \mathbf{r}\nabla \cdot \mathbf{J} \tag{55}$$

$$\int_V \mathbf{J} d^3\mathbf{r} = \int_V \frac{\partial}{\partial x_k}(x_i J_k) - \int_V \mathbf{r}\nabla \cdot \mathbf{J} d^3\mathbf{r}$$

$$-\int_V \mathbf{r}\nabla \cdot \mathbf{J}d^3\mathbf{r} \quad (56)$$

and the amusing integral identity

$$\int_{-\infty}^{\infty} F(f(x))dx = \int_{-\infty}^{\infty} F(x)dx, \quad (57)$$

where F is any function and

$$f(x) = x - \sum_{n=0}^{\infty} \frac{a_n}{x + b_n} \quad (58)$$

as long as $a_n \geq 0$ and b_n is real (Glasser 1983).

Integrals OF THE FORM

$$\int_a^b f(x)dx \quad (59)$$

with one INFINITE LIMIT and the other NONZERO may be expressed as finite integrals over transformed functions. If $f(x)$ decreases at least as fast as $1/x^2$, then let

$$t \equiv \frac{1}{x} \quad (60)$$

$$dt = -\frac{dx}{x^2} \quad (61)$$

$$dx = -x^2 dt = -\frac{dt}{t^2}, \quad (62)$$

and

$$\int_a^b f(x)dx = -\int_{1/a}^{1/b} \frac{1}{t^2} f\left(\frac{1}{t}\right)dt = \int_{1/b}^{1/a} \frac{1}{t^2} f\left(\frac{1}{t}\right)dt. \quad (63)$$

If $f(x)$ diverges as $(x-a)^\gamma$ for $\gamma \in [0, 1]$, let

$$x \equiv t^{1/(1-\gamma)} + a \quad (64)$$

$$dx = \frac{1}{1-\gamma} t^{1/(1-\gamma)-1} dt = \frac{1}{1-\gamma} t^{[1-(1-\gamma)]/(1-\gamma)} dt$$

$$= \frac{1}{\gamma - 1} t^{\gamma/(1-\gamma)} dt \quad (65)$$

$$t = (x-a)^{1-\gamma}, \quad (66)$$

and

$$\int_a^b f(x)dx = \frac{1}{1-\gamma} = \int_0^{(b-a)^{1-\gamma}} t^{\gamma(1-\gamma)} f\left(t^{1/(1-\gamma)} + a\right)dt. \quad (67)$$

If $f(x)$ diverges as $(x+b)^\gamma$ for $\gamma \in [0, 1]$, let

$$x \equiv b - t^{1/(1-\gamma)} \quad (68)$$

$$dx = -\frac{1}{\gamma - 1} t^{\gamma/(1-\gamma)} dt \quad (69)$$

$$t = (b-x)^{1-\gamma}, \quad (70)$$

and

$$\int_a^b f(x)dx = \frac{1}{1-\gamma} = \int_0^{(b-a)^{1-\gamma}} t^{\gamma/(1-\gamma)} f(b - t^{1/(1-\gamma)} dt. \quad (71)$$

If the integral diverges exponentially, then let

$$t \equiv e^{-x} \quad (72)$$

$$dt = -e^{-x} dx \quad (73)$$

$$x = -\ln t, \quad (74)$$

and

$$\int_a^\infty f(x)dx = \int_0^{e^{-a}} f(-\ln t)\frac{dt}{t}. \quad (75)$$

Integrals with rational exponents can often be solved by making the substitution $u = x^{1/n}$, where n is the LEAST COMMON MULTIPLE of the DENOMINATOR of the exponents.

Integration rules include

$$\int_a^a f(x)dx = 0 \quad (76)$$

$$\int_a^b f(x)dx = -\int_b^a f(x)dx. \quad (77)$$

For $c \in (a, b)$,

$$\int_a^b f(x)dx = \int_a^c f(x)dx + \int_c^b f(x)dx. \quad (78)$$

If g' is continuous on $[a, b]$ and f is continuous and has an antiderivative on an INTERVAL containing the values of $g(x)$ for $a \leq x \leq b$, then

$$\int_a^b f(g(x))g'(x)dx = \int_{g(a)}^{g(b)} f(u)du. \quad (79)$$

Liouville showed that the integrals

$$\int e^{-x^2} dx \int \frac{e^x}{x} dx \int \frac{\sin x}{x} dx \int \frac{dx}{\ln x} \quad (80)$$

cannot be expressed as terms of a finite number of elementary functions. Other irreducibles include

$$\int x^x dx \int x^{-x} dx \int \sqrt{\sin x}\, dx. \quad (81)$$

Chebyshev proved that if U, V, and W are RATIONAL NUMBERS, then

$$\int x^U \left(A + Bx^V\right)^W dx \quad (82)$$

is integrable in terms of elementary functions IFF $(U+1)/V$, W, or $W + (U+1)/V$ is an INTEGER (Ritt 1948, Shanks 1993).

Integral Equation

If the limits are fixed, an integral equation is called a Fredholm integral equation. If one limit is variable, it is called a Volterra integral equation. If the unknown

function is only under the integral sign, the equation is said to be of the "first kind." If the function is both inside and outside, the equation is called of the "second kind." A Fredholm equation of the first kind is OF THE FORM

$$f(x)=\int_a^b K(x,t)\phi(t)dt. \tag{1}$$

A Fredholm equation of the second kind is OF THE FORM

$$\phi(x)=f(x)+\int_a^b K(x,t)\phi(t)dt. \tag{2}$$

A Volterra equation of the first kind is OF THE FORM

$$f(x)=\int_a^x K(x,t)\phi(t)dt. \tag{3}$$

A Volterra equation of the second kind is OF THE FORM

$$\phi(x)=f(x)+\int_a^x K(x,t)\phi(t)dt, \tag{4}$$

where the functions $K(x,t)$ are known as KERNELS. Integral equations may be solved directly if they are SEPARABLE. Otherwise, a NEUMANN SERIES must be used.

A KERNEL is separable if

$$K(x,t)=\lambda\sum_{j=1}^n M_j(x)N_j(t). \tag{5}$$

This condition is satisfied by all POLYNOMIALS and many TRANSCENDENTAL FUNCTIONS. a FREDHOLM INTEGRAL EQUATION OF THE SECOND KIND with separable KERNEL may be solved as follows:

$$\phi(x)=f(x)+\int_a^b K(x,t)\phi(t)dt$$

$$=f(x)+\lambda\sum_{j=1}^n M_j(x)\int_a^b N_j(t)\phi(t)dt$$

$$=f(x)+\lambda\sum_{j=1}^n c_jM_j(x), \tag{6}$$

where

$$c_j\equiv\int_a^b N_j(t)\phi(t)dt. \tag{7}$$

Now multiply both sides of (7) by $N_i(x)$ and integrate over dx.

$$\int_a^b \phi(x)N_i(x)dx$$

$$=\int_a^b f(x)N_i(x)dx+\lambda\sum_{j=1}^n c_j\int_a^b M_j(x)N_i(x)dx. \tag{8}$$

By (7), the first term is just c_i. Now define

$$b_i\equiv\int_a^b N_i(x)f(x)dx \tag{9}$$

$$a_{ij}=\int_a^b N_i(x)M_j(x)dx, \tag{10}$$

so (8) becomes

$$c_i=b_i+\lambda\sum_{j=1}^n a_{ij}c_j \tag{11}$$

Writing this in matrix form,

$$\mathbf{C}=\mathbf{B}+\lambda\mathsf{A}\mathbf{C}, \tag{12}$$

so

$$(\mathsf{I}-\lambda\mathsf{A})\mathbf{C}=\mathbf{B} \tag{13}$$

$$\mathbf{C}=(\mathsf{I}-\lambda\mathsf{A})^{-1}\mathbf{B} \tag{14}$$

Integral of Motion

A function of the coordinates which is constant along a trajectory in PHASE SPACE. The number of DEGREES OF FREEDOM of a DYNAMICAL SYSTEM such as the DUFFING DIFFERENTIAL EQUATION can be decreased by one if an integral of motion can be found. In general, it is very difficult to discover integrals of motion.

Integral Polyhedron

PRIMITIVE POLYTOPE

Integral Polynomial

INTEGER POLYNOMIAL

Integral Sign

The symbol $\int$ used to denote an INTEGRAL $\int f(x)dx$. The symbol was invented by Leibniz and chosen to be a stylized script "S" to stand for "summation."

See also INTEGRAL, INTEGRATION UNDER THE INTEGRAL SIGN

Integral Test

Let Σu_k be a series with POSITIVE terms and let $f(x)$ be the function that results when k is replaced by x in the FORMULA for u_k. If f is decreasing and continuous for $x \geq 1$ and

$$\lim_{x\to\infty} f(x) = 0,$$

then

$$\sum_{k=1}^{\infty} u_k$$

and

$$\int_t^{\infty} f(x)dx$$

both converge or diverge, where $1 \leq t \leq \infty$. The test is also called the CAUCHY INTEGRAL TEST or MACLAURIN INTEGRAL TEST.

See also CONVERGENCE TESTS

References

Shenitzer, A. and Steprans, S. J. "The Evolution of Integration." *Amer. Math. Monthly* **101**, 66–72, 1994.

Integration (Form)

A DIFFERENTIAL K-FORM can be integrated on an n-dimensional MANIFOLD. The basic example is an n-form α in the open unit ball in $\mathbb{R}^n$. Since α is a TOP-DIMENSIONAL FORM, it can be written $\alpha = f dx_1 \wedge \ldots \wedge dx_n$ and so

$$\int_B \alpha = \int_B f \ d\mu, \tag{1}$$

where the integral is the LEBESGUE INTEGRAL.

On a MANIFOLD M covered by COORDINATE CHARTS U_i, there is a PARTITION OF UNITY ρ_i such that

1. ρ_i is SUPPORTED in U_i and
2. $\Sigma \rho_i = 1$.

Then

$$\int_M \alpha = \sum \int_{U_i} \rho_i \alpha, \tag{2}$$

where the right-hand side is WELL DEFINED because each integration takes place in a COORDINATE CHART. The integral of the n-form α is WELL DEFINED because, under a change of coordinates $g : X \to Y$, the integral transforms according to the determinant of the JACOBIAN, while an n-form pulls back by the determinant of the JACOBIAN. Hence,

$$\int_X g^*(\alpha) = \int_X ||J|| f(g(x)) = \int_Y f(y) \tag{3}$$

is the same integral in either COORDINATE CHART.

For example, it is possible to integrate the 2-form

$$\alpha = z \ dx \wedge dy - y \ dx \wedge dz + x \ dy \wedge dz \tag{4}$$

on the SPHERE $\mathbb{S}^2$. Because a point has MEASURE ZERO, it is enough to integrate α on $\mathbb{S}^2 - (0, 0, 1)$, which can be covered by STEREOGRAPHIC PROJECTION $\phi : \mathbb{R}^2 \to \mathbb{S}^2 - (0, 0, 1)$. Since

$$\phi(x, y) = \left(\frac{2x}{1 + r^2}, \frac{2y}{1 + r^2}, \frac{1 - r^2}{1 + r^2} \right) \tag{5}$$

the PULLBACK MAP of α is

$$\phi^*(\alpha) = \frac{4}{(1 + r^2)^2} dx \wedge dy, \tag{6}$$

the integral of α on $\mathbb{S}^2$ is

$$\int\int \frac{4}{(1 + r^2)^2} 2\pi r \ d\theta = 4\pi. \tag{7}$$

Note that this computation is done more easily by STOKES' THEOREM, because $d\alpha = 3dx \wedge dy \wedge dz$.

See also DE RHAM COHOMOLOGY, STOKES' THEOREM, SUBMANIFOLD, TOP-DIMENSIONAL FORM, VOLUME FORM

Integration by Parts

Integration by parts is a technique for performing definite integration $\int u \ dv$ by expanding the differential of a product of functions $d(uv)$ and expressing the original integral in terms of a known integral $\int v \ du$. A single integration by parts starts with

$$d(uv) = u \ dv + v \ du, \tag{1}$$

and integrates both sides,

$$\int d(uv) = uv = \int u \ dv + \int v \ du. \tag{2}$$

Rearranging gives

$$\int u \ dv = uv - \int v \ du, \tag{3}$$

so

$$\int_a^b u \ dv = [uv]_a^b - \int_{f(a)}^{f(b)} v \ du, \tag{4}$$

where $[f]_a^b = f(b) - f(a)$.

This procedure can also be applied n times to $\int f^{(n)}(x) g(x) dx$.

$$u = g(x) \quad dv = f^{(n)}(x) dx \tag{5}$$

$$du = g'(x) dx \quad v = f^{(n-1)}(x). \tag{6}$$

Therefore,

$$\int f^{(n)} g(x) dx = g(x) f^{(n-1)}(x) - \int f^{(n-1)}(x) g'(x) dx. \tag{7}$$

But

$$\int f^{(n-1)}(x) g'(x) dx = g'(x) f^{(n-2)}(x) - \int f^{(n-2)}(x) g''(x) dx \tag{8}$$

$$\int f^{(n-2)}(x)g''(x)dx$$
$$= g''(x)f^{(n-3)}(x) - \int f^{(n-3)}(x)g^{(3)}(x)dx, \quad (9)$$

so

$$\int f^{(n)}(x)g(x)dx = g(x)f^{(n-1)}(x) - g'(x)f^{(n-2)}(x)$$
$$+ g(x)f^{(n-3)}(x) - \ldots + (-1)^n \int f(x)g^{(n)}(x)dx. \quad (10)$$

Now consider this in the slightly different form $\int f(x)g(x)dx$. Integrate by parts a first time

$$u = f(x) \quad dv = g(x)dx \quad (11)$$

$$du = f'(x)dx \quad v = \int g(x)dx, \quad (12)$$

so

$$\int f(x)g(x)dx = f(x)\int g(x)dx - \int \left[\int g(x)dx\right] f'(x)dx. \quad (13)$$

Now integrate by parts a second time,

$$u = f'(x) \quad dv = \int g(x)dx \quad (14)$$

$$du = f''(x)dx \quad v = \int\int g(x)(dx)^2, \quad (15)$$

so

$$\int f(x)g(x)dx = f(x)\int g(x)dx - f'(x)\int\int g(x)(dx)^2$$
$$+ \int \left[\int\int g(x)(dx)^2\right] f''(x)dx. \quad (16)$$

Repeating a third time,

$$\int f(x)g(x)dx = f(x)\int g(x)dx - f'(x)\int\int g(x)(dx)^2$$
$$+ f''(x)\int\int\int g(x)(dx)^3 - \int\left[\int\int\int g(x)(dx)^3\right] f'''(x)dx. \quad (17)$$

Therefore, after n applications,

$$\int f(x)g(x)dx = f(x)\int g(x)dx - f'(x)\int\int g(x)(dx)^2$$
$$+ f''(x)\int\int\int g(x)(dx)^3 - \ldots$$
$$+ (-1)^{n+1} f^{(n)}(x) \underbrace{\int\cdots\int}_{n+1} g(x)(dx)^{n+1}$$
$$+ (-1)^n \int \left[\underbrace{\int\cdots\int}_{n+1} g(x)(dx)^{n+1}\right] f^{(n+1)}(x)dx.$$

(18)

If $f^{n+1}(x) = 0$ (e.g., for an nth degree POLYNOMIAL), the last term is 0, so the sum terminates after n terms and

$$\int f(x)g(x)dx = f(x)\int g(x)dx$$
$$- f'(x)\int\int g(x)(dx)^2 + f''(x)\int\int\int g(x)(dx)^3 - \ldots$$
$$+ (-1)^{n+1} f^{(n)}(x) \underbrace{\int\cdots\int}_{n+1} g(x)(dx)^{n+1}. \quad (19)$$

Integration Theory

MEASURE THEORY

Integration Under the Integral Sign

The use of the identity

$$\int_a^b dx \int_{\alpha_0}^{\alpha} f(x, \alpha)d\alpha = \int_{\alpha_0}^{\alpha} d\alpha \int_a^b f(x, \alpha)dx \quad (1)$$

to compute an INTEGRAL. For example, consider

$$\int_0^1 x^\alpha dx = \frac{1}{\alpha + 1} \quad (2)$$

for $\alpha > -1$. Multiplying by $d\alpha$ and integrating between a and b gives

$$\int_c^b d\alpha \int_0^1 x^\alpha dx = \int_a^b \frac{d\alpha}{\alpha+1} = \ln\left(\frac{b+1}{a+1}\right). \quad (3)$$

But the left-hand side is equal to

$$\int_0^1 d\alpha \int_a^b x^\alpha d\alpha = \int_0^1 \frac{x^b - x^a}{\ln x} dx, \quad (4)$$

so it follows that

$$\int_0^1 \frac{x^b - x^a}{\ln x} dx = \ln\left(\frac{b+1}{a+1}\right) \quad (5)$$

(Woods 1926, pp. 145–146).

Interchange Graph

LINE GRAPH

Interest

Interest is a fee (or payment) made for the borrowing (or lending) of money. The two most common types of interest are SIMPLE INTEREST, for which interest is paid only on the initial PRINCIPAL, and COMPOUND INTEREST, for which interest earned can be re-invested to generate further interest.

See also COMPOUND INTEREST, CONVERSION PERIOD, PRESENT VALUE, RULE OF 72, SIMPLE INTEREST

References

Kellison, S. G. *Theory of Interest, 2nd ed.* Burr Ridge, IL: Richard D. Irwin, 1991.

Interior

That portion of a region lying "inside" a specified boundary. For example, the interior of the SPHERE is a BALL.

See also EXTERIOR

Interior Angle Bisector

ANGLE BISECTOR

Interior Product

The interior product is a dual notion of the EXTERIOR PRODUCT in an EXTERIOR ALGEBRA ΛV, where V is a VECTOR SPACE. Given an ORTHONORMAL BASIS $\{e_i\}$ of V, the forms

$$\{e_{i_1} \wedge \ldots \wedge e_{i_p}\} i_1 < \ldots < i_p \quad (1)$$

are an ORTHONORMAL BASIS for $\Lambda^p V$. They define a metric on the EXTERIOR ALGEBRA, $\langle \alpha, \beta \rangle$. The interior product with a form γ is the ADJOINT of the EXTERIOR PRODUCT with γ. That is,

$$\langle \alpha \lrcorner \gamma, \beta \rangle = \langle \alpha, \beta \wedge \gamma \rangle \quad (2)$$

for all β. For example,

$$e_1 \wedge e_2 \lrcorner e_3 = 0 \quad (3)$$

and

$$e_1 \wedge e_2 \wedge e_3 \wedge e_4 \lrcorner e_1 \wedge e_4 = e_2 \wedge e_3, \quad (4)$$

where the e_i are ORTHONORMAL, are two interior products.

An inner product on V gives an isomorphism $e : V \simeq V^*$ with the DUAL SPACE V^*. The interior product is the composition of this isomorphism with CONTRACTION.

See also CONTRACTION (TENSOR), EXTERIOR ALGEBRA, EXTERIOR PRODUCT, INNER PRODUCT, WEDGE PRODUCT

Intermediate Value Theorem

If f is continuous on a CLOSED INTERVAL $[a, b]$, and c is any number between $f(a)$ and $f(b)$ inclusive, then there is at least one number x in the CLOSED INTERVAL such that $f(x) = c$.

Interquartile Range

Divide a set of data into two groups (high and low) of equal size at the median if there is an even number of data points, or two groups consisting of points on either side of the median itself plus the median if there is an odd number of data points. Find the medians of the low and high groups, denoting these first and third quartiles by Q_1 and Q_3. The interquartile range is then defined by

$$\mathrm{IQR} \equiv Q_3 - Q_1.$$

Intersecting Cylinders

Steinmetz Solid

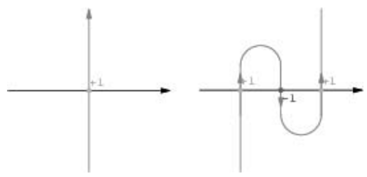
Intersecting Lines

Line-Line Intersection

Intersecting Spheres

Sphere-Sphere Intersection

Intersection



The intersection of two sets A and B is the set of elements common to A and B. This is written $A \cap B$, and is pronounced "A intersection B" or "A cap B." The intersection of sets A_1 through A_n is written $\cap_{i=1}^n A_i$.

The intersection of two lines AB and CD is written $AB \cap CD$. The intersection of two or more geometric objects is the point (points, lines, etc.) at which they concur.

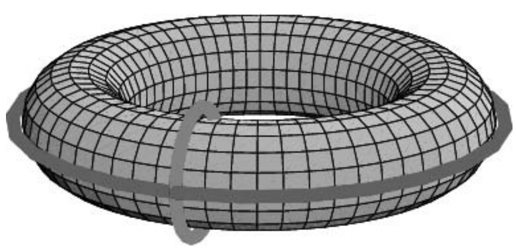
Intersection (Homology)



When two cycles intersect TRANSVERSALLY $X_1 \cap X_2 = Y$ on a SMOOTH MANIFOLD M, then Y is a cycle. Moreover, the homology class that Y represents depends only on the HOMOLOGY CLASS of X_1 and X_2. The sign of Y is determined by the orientations on M, X_1, and X_2.

For example, two curves can intersect in one point on a surface transversally, since

$$\dim X_1 + \dim X_2 = 1 + 1 = 2 = \dim M - 0.$$

The curves can be deformed so that they intersect three times, but two of those intersections sum to zero since two intersect positively and one intersects negatively, i.e., with the ORIENTATION of the curves being the reverse orientation of the ambient space.

On the torus illustrated above, the cycles intersect in one point.

The binary operation of intersection makes homology on a MANIFOLD into a RING. That is, it plays the role of multiplication, which respects the grading. When $\alpha \in H_{n-p}$ and $\alpha \in H_{n-q}$, then $\alpha \cap \beta \in H_{n-(p+q)}$. In fact, intersection is the dual to the CUP PRODUCT in POINCARÉ DUALITY. That is, if $\alpha \in H^p$ is the POINCARÉ DUAL to $A \in H_{n-p}$ and $\beta \in H^q$ is the dual to $B \in H_{n-q}$ then $\alpha \wedge \beta \in H^{p+q}$ is the dual to $A \cap B \in H_{n-(p+q)}$.

Without the notion of TRANSVERSALITY, intersections are not well-defined in HOMOLOGY. On a more general space, even a manifold with singularities, the homology does not have a natural ring structure.

See also CODIMENSION, CUP PRODUCT, HOMOLOGY, MANIFOLD, ORIENTATION (MANIFOLD), ORIENTATION (VECTOR SPACE), POINCARE DUALITY, TRANSVERSAL INTERSECTION

Intersection Array

Given a DISTANCE-REGULAR GRAPH G with integers $b_i, c_i, i = 0, \ldots, d$ such that for any two vertices $x, y \in G$ at distance $i = d(x, y)$, there are exactly c_i neighbors of $y \in G_{i-1}(x)$ and b_i neighbors of $y \in G_{i+1}(x)$, the sequence

$$i(\gamma) = \{b_0, b_1, \ldots, b_{d-1}; c_1, \ldots, c_d\}$$

is called the intersection array of G.

Intersection Graph

GRAPH INTERSECTION

Intersection Number

The intersection number $\omega(G)$ of a given GRAPH G is the minimum number of elements in a set S such that G is an intersection graph on S.

See also GRAPH INTERSECTION

References

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, 1994.

Interspersion

An ARRAY $A = a_{ij},\ i, j \geq 1$ of POSITIVE INTEGERS is called an interspersion if

1. The rows of A comprise a PARTITION of the POSITIVE INTEGERS,
2. Every row of A is an INCREASING SEQUENCE,
3. Every column of A is a (possibly FINITE) INCREASING SEQUENCE,
4. If (u_j) and (v_j) are distinct rows of A and if p and q are any indices for which $u_p < v_q < u_{p+1}$, then $u_{p+1} < v_{q+1} < u_{p+2}$.

If an array $A = a_{ij}$ is an interspersion, then it is a DISPERSION. If an array $A = a(i, j)$ is an interspersion, then the sequence $\{x_n\}$ given by $\{x_n = i : n = (i, j)\}$ for some j is a FRACTAL SEQUENCE. Examples of interspersion are the STOLARSKY ARRAY and WYTHOFF ARRAY.

See also DISPERSION (SEQUENCE), FRACTAL SEQUENCE, STOLARSKY ARRAY

Intersphere

MIDSPHERE

Interval

A collection of points on a LINE SEGMENT. If the endpoints a and b are FINITE and are included, the interval is called CLOSED and is denoted $[a, b]$. If one of the endpoints is $\pm\infty$, then the interval still contains all of its LIMIT POINTS, so $[a, \infty)$ and $(-\infty, b]$ are also closed intervals. If the endpoints are not included, the interval is called OPEN and denoted (a, b). If one endpoint is included but not the other, the interval is denoted $[a, b)$ or $(a, b]$ and is called a HALF-CLOSED (or HALF-OPEN) interval.

The non-standard notation $]a, b[$ for an OPEN INTERVAL and $[a, b[$ or $]a, b]$ for a HALF-CLOSED INTERVAL is sometimes also used.

See also CLOSED INTERVAL, HALF-CLOSED INTERVAL, LIMIT POINT, OPEN INTERVAL, PENCIL

Interval Graph

A GRAPH $G=(V,E)$ is an interval graph if it captures the INTERSECTION RELATION for some set of INTERVALS on the REAL LINE. Formally, P is an interval graph provided that one can assign to each $v \in V$ an interval I_v such that $I_u \cap I_v$ is nonempty precisely when $uv \in E$. An interval graph on a list l can be generated using `IntervalGraph[l]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

STAR GRAPHS are interval graphs, but CYCLE GRAPHS are not (Skiena 1990, p. 164). Determining if a graph is an interval graph and realizing it can be done in $\mathcal{O}(n)$ time (Booth and Lueker 1976; Skiena 1990, p. 164).

Interval Order

A POSET $P=(X,\leq)$ is an interval order if it is ISOMORPHIC to some set of INTERVALS on the REAL LINE ordered by left-to-right precedence. Formally, P is an interval order provided that one can assign to each $x \in X$ an INTERVAL $[x_L, x_R]$ such that $x_R < y_L$ in the REAL NUMBERS IFF $x < y$ in P.

Intrinsic Curvature

A CURVATURE such as GAUSSIAN CURVATURE which is detectable to the "inhabitants" of a surface and not just outside observers. An EXTRINSIC CURVATURE, on the other hand, is not detectable to someone who can't study the 3-dimensional space surrounding the surface on which he resides.

See also CURVATURE, EXTRINSIC CURVATURE, GAUSSIAN CURVATURE

Intrinsic Equation

An equation which specifies a CURVE in terms of intrinsic properties such as ARC LENGTH, RADIUS OF CURVATURE, and TANGENTIAL ANGLE instead of with reference to artificial coordinate axes. Intrinsic equations are also called NATURAL EQUATIONS.

See also CESÀRO EQUATION, NATURAL EQUATION, WHEWELL EQUATION

Intrinsic Variety

See also VARIETY

Intrinsically Linked

A GRAPH is intrinsically linked if any embedding of it in 3-D contains a nontrivial link. A GRAPH is intrinsically linked IFF it contains one of the seven PETERSEN GRAPHS (Robertson *et al.* 1993).

The COMPLETE GRAPH K_6 (left) is intrinsically linked because it contains at least two linked TRIANGLES. The COMPLETE k-PARTITE GRAPH $K_{3,3,1}$ (right) is also intrinsically linked.

Invariant (Elliptic Function)

The invariants of a WEIERSTRASS ELLIPTIC FUNCTION $\wp(z|\omega_1, \omega_2)$ are defined by the EISENSTEIN SERIES

$$g_2(\omega_1, \omega_2) \equiv 60 \sum_{m,n}{}' \Omega_{m,n}^{-4}$$

$$g_3(\omega_1, \omega_2) \equiv 140 \sum_{m,n}{}' \Omega_{m,n}^{-5}.$$

Here,

$$\Omega_{mn}(\omega_1, \omega_2) \equiv 2m\omega_1 - 2n\omega_2,$$

where ω_1 and ω_2 are the periods of the ELLIPTIC FUNCTION.

Writing $g_i(\tau) \equiv g_i(1, \tau)$,

$$g_2(\tau) \equiv g_2(1, \tau) = \omega_1^4(\omega_1, \omega_2) \tag{1}$$

$$g_3(\tau) \equiv g_3(1, \tau) = \omega_1^6(\omega_1, \omega_2), \tag{2}$$

and the invariants have the FOURIER SERIES

$$g_2(\tau) = \frac{4\pi^4}{4}\left[1 + 240\sum_{k=1}^{\infty} \sigma_3(k) e^{2\pi i k\tau}\right] \tag{3}$$

$$g_3(\tau) = \frac{8\pi^6}{27}\left[1 - 504\sum_{k=1}^{\infty} \sigma_5(k) e^{2\pi i k\tau}\right] \tag{4}$$

where $\tau \equiv \omega_2/\omega_2$ and $\sigma_k(n)$ is the DIVISOR FUNCTION (Apostol 1997).

Invariant Manifold

When stable and unstable invariant MANIFOLDS intersect, they do so in a HYPERBOLIC FIXED POINT (SADDLE POINT). The invariant MANIFOLDS are then called SEPARATRICES. A HYPERBOLIC FIXED POINT is characterized by two ingoing stable MANIFOLDS and two outgoing unstable MANIFOLDS. In integrable systems, incoming W^s and outgoing W^u MANIFOLDS all join up smoothly.

A stable invariant MANIFOLD W^s of a FIXED POINT Y^* is the set of all points Y_0 such that the trajectory passing through Y_0 tends to Y^* as $j \to \infty$.

An unstable invariant MANIFOLD W^u of a FIXED POINT Y^* is the set of all points Y_0 such that the trajectory passing through Y_0 tends to Y^* as $j \to -\infty$.

See also HOMOCLINIC POINT

Invariant Point

FIXED POINT (TRANSFORMATION)

Invariant Series

An invariant series of a GROUP G is a NORMAL SERIES

$$I = A_0 \lhd A_1 \lhd \ldots \lhd A_r = G$$

such that each $A_i \lhd G$, where $H \lhd G$ means that H is a NORMAL SUBGROUP of G.

Invariant Subgroup

NORMAL SUBGROUP

Inverse Cosecant

The function $\csc^{-1} x$, also denoted $\operatorname{arccsc}(x)$, where $\csc x$ is the COSECANT and the SUPERSCRIPT -1 denotes an INVERSE FUNCTION, *not* the multiplicative inverse. The inverse cosecant is implemented as `ArcCsc[x]` in *Mathematica*. The inverse cosecant satisfies

$$\csc^{-1} x = \sec^{-1}\left(\frac{x}{\sqrt{x^2 - 1}}\right) \tag{1}$$

for POSITIVE or NEGATIVE x, and

$$\csc^{-1} x = \pi + \csc^{-1}(-x) \tag{2}$$

for $x \geq 0$. The inverse cosecant has TAYLOR SERIES about infinity of

$$\csc^{-1} x = x^{-1} + \tfrac{1}{6}x^{-3} + \tfrac{3}{40}x^{-5} + \tfrac{5}{112}x^{-7} + \ldots. \tag{3}$$

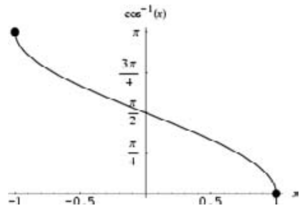
The inverse cosecant is given in terms of other inverse trigonometric functions by

$$\csc^{-1} x = \cos^{-1}\left(\frac{\sqrt{x^2 - 1}}{x}\right) \tag{4}$$

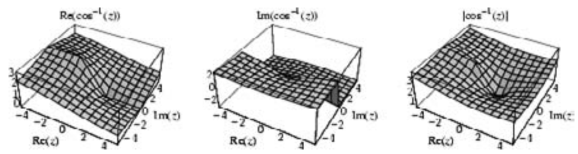
$$= \cot^{-1}\left(\sqrt{x^2 - 1}\right) \tag{5}$$

$$= \tfrac{1}{2}\pi - \sec^{-1} x = -\tfrac{1}{2}\pi - \sec^{-1}(-x) \tag{6}$$

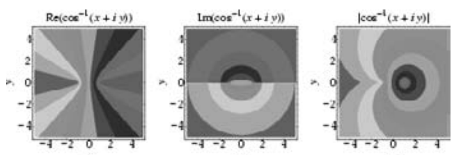
$$= \sin^{-1}\left(\frac{1}{x}\right) \tag{7}$$



for $x \geq 0$.



See also COSECANT, INVERSE SINE, SINE



References

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, pp. 142–143, 1987.

Inverse Cosine

The function $\cos^{-1} x$, where $\cos x$ is the COSINE and the superscript -1 denotes the INVERSE FUNCTION, *not* the multiplicative inverse. The notation $\arccos x$ or Arccos$x$ is sometimes also used. The inverse cosine is implemented as `ArcCos[x]` in *Mathematica*. The inverse cosine satisfies

$$\cos^{-1} x = \pi - \cos^{-1}(-x) \tag{1}$$

for POSITIVE and NEGATIVE x, and

$$\cos^{-1} x = \begin{cases} \tfrac{1}{2}\pi - \cos^{-1}\left(\sqrt{1-x^2}\right) & \text{for } 0 \le x \le 1 \\ \tfrac{1}{2}\pi \ + \cos^{-1}\left(\sqrt{1-x^2}\right) & \text{for } -1 \le x \le 0. \end{cases} \tag{2}$$

The MACLAURIN SERIES for the inverse cosine with $-1 \le x \le 1$ is

$$\cos^{-1} x = \tfrac{1}{2}\pi - x - \tfrac{1}{6}x^3 - \tfrac{3}{40}x^5 - \tfrac{5}{112}x^7 - \tfrac{35}{1152}x^9 - \ldots. \tag{3}$$

The inverse cosine is given in terms of other inverse trigonometric functions by

$$\cos^{-1} x = \cot^{-1}\left(\frac{x}{\sqrt{1-x^2}}\right) \tag{4}$$

$$= \tfrac{1}{2}\pi + \sin^{-1}(-x) = \tfrac{1}{2}\pi - \sin^{-1} x \tag{5}$$

$$= \tfrac{1}{2}\pi - \tan^{-1}\left(\frac{x}{\sqrt{1-x^2}}\right) \tag{6}$$

for POSITIVE or NEGATIVE x, and

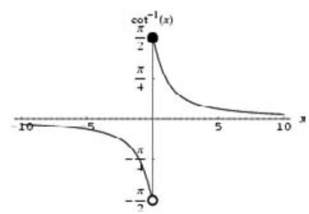
$$\cos^{-1} x = \csc^{-1}\left(\frac{1}{\sqrt{1-x^2}}\right) \tag{7}$$

$$= \sec^{-1}\left(\frac{1}{x}\right) \tag{8}$$

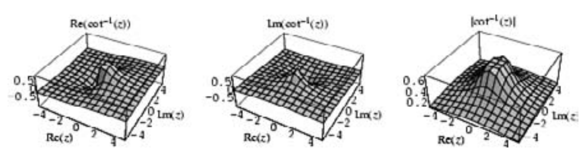
$$= \sin^{-1}\left(\sqrt{1-x^2}\right) \tag{9}$$

$$= \tan^{-1}\left(\frac{\sqrt{1-x^2}}{x}\right) \tag{10}$$

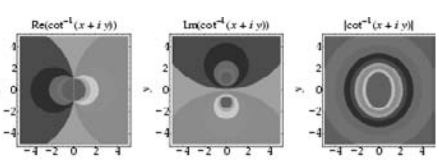
for $x \ge 0$.



See also COSINE, INVERSE SECANT



References



Abramowitz, M. and Stegun, C. A. (Eds.). "Inverse Circular Functions." §4.4 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, pp. 79–83, 1972.

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, pp. 142–143 and 219, 1987.

Inverse Cotangent

The function $\cot^{-1} x$, also denoted $\operatorname{arccot}(x)$, where $\cot x$ is the COTANGENT and the superscript -1 denotes an INVERSE FUNCTION and *not* the multiplicative inverse. The inverse cotangent is implemented as `ArcCot[x]` in *Mathematica*.

The MACLAURIN SERIES of the inverse cotangent is given by

$$\cot^{-1} x = \tfrac{1}{2}\pi - x + \tfrac{1}{3}x^3 - \tfrac{1}{5}x^5 + \tfrac{1}{7}x^7 - \tfrac{1}{9}x^9 + \ldots, \tag{1}$$

and LAURENT SERIES by

$$\cot^{-1} x = x^{-1} - \tfrac{1}{3}x^{-3} + \tfrac{1}{5}x^{-5} - \tfrac{1}{7}x^{-7} + \tfrac{1}{9}x^{-9} + \ldots. \quad (2)$$

Euler derived the INFINITE series

$$\cot^{-1} x = x\left[\frac{1}{x^2+1} + \frac{2}{3(x^2+1)^2} + \frac{2\cdot 4}{3\cdot 5(x^2+1)^3} + \ldots\right] \quad (3)$$

(Wetherfield 1996).

The inverse cotangent satisfies

$$\cot^{-1} x = \tan^{-1}\left(\frac{1}{x}\right) \quad (4)$$

$$= -\cot^{-1}(-x) \quad (5)$$

for POSITIVE and NEGATIVE x, and

$$\cot^{-1} x = \cos^{-1}\left(\frac{x}{\sqrt{x^2+1}}\right) \quad (6)$$

$$= \tfrac{1}{2}\pi - \cot^{-1}\left(\frac{1}{x}\right) \quad (7)$$

$$= \csc^{-1}(\sqrt{x^2+1}) \quad (8)$$

$$= \sec^{-1}\left(\frac{\sqrt{x^2+1}}{x}\right) \quad (9)$$

$$= \sin^{-1}\left(\frac{1}{\sqrt{x^2+1}}\right) \quad (10)$$

$$= \tfrac{1}{2}\pi - \sin^{-1}\left(\frac{x}{\sqrt{x^2+1}}\right) \quad (11)$$

$$= \tfrac{1}{2}\pi + \tan^{-1}(-x) \quad (12)$$

$$= \tfrac{1}{2}\pi - \tan^{-1} x \quad (13)$$

for $x \geq 0$.

A number

$$t_x = \cot^{-1} x, \quad (14)$$

where x is an INTEGER or RATIONAL NUMBER, is sometimes called a GREGORY NUMBER. Lehmer (1938a) showed that $\cot^{-1}(a/b)$ can be expressed as a finite sum of inverse cotangents of INTEGER arguments

$$\cot^{-1}\left(\frac{a}{b}\right) = \sum_{i=1}^{k} (-1)^{i-1}\cot^{-1} n_i, \quad (15)$$

where

$$n_i = \left\lfloor \frac{a_i}{b_i} \right\rfloor, \quad (16)$$

with $\lfloor x \rfloor$ the FLOOR FUNCTION, and

$$a_{i+1} = a_i n + i + b_i \quad (17)$$

$$b_{i+1} = a_i - n_i b_i, \quad (18)$$

with $a_0 = a$ and $b_0 = b$, and where the recurrence is continued until $b_{k+1} = 0$. If an INVERSE TANGENT sum is written as

$$\tan^{-1} n = \sum_{k=1} f_k \tan^{-1} n_k + f \tan^{-1} 1, \quad (19)$$

then equation (15) becomes

$$\cot^{-1} n = \sum_{k=1} f_k \cot^{-1} n_k + c \cot^{-1} 1, \quad (20)$$

where

$$c = 2 - f - 2\sum_{k=1} f_k. \quad (21)$$

Inverse cotangent sums can be used to generate MACHIN-LIKE FORMULAS.

An interesting inverse cotangent identity attributed to Charles Dodgson (Lewis Carroll) by Lehmer (1938b; Bromwich 1965, Castellanos 1988ab) is

$$\cot^{-1}(p+r) + \tan^{-1}(p+q) = \tan^{-1} p, \quad (22)$$

where

$$1 + p^2 = qr. \quad (23)$$

Other inverse cotangent identities include

$$2\cot^{-1}(2x) - \cot^{-1} x = \cot^{-1}(4x^3 + 3x) \quad (24)$$

$$3\cot^{-1}(3x) - \cot^{-1} x = \cot^{-1}\left(\frac{27x^4 + 18x^2 - 1}{8x}\right), \quad (25)$$

as well as many others (Bennett 1926, Lehmer 1938b).

Inverse Curve

Given a circle C with center O and radius k, then two points P and Q are inverse with respect to C if $OP \cdot OQ = k^2$. If P describes a curve C_1, then Q describes a curve C_2 called the inverse of C_1 with respect to the circle C (with inversion center O). The Peaucellier inversor can be used to construct an inverse curve from a given curve.

If the polar equation of C is $r(\theta)$, then the inverse curve has polar equation

$$r = \frac{k^2}{r(\theta)}.$$

If $O = (x_0, y_0)$ and $P = (f(t), g(t))$, then the inverse has equations

$$x = x_0 + \frac{k^2(f - x_0)}{(f - x_0)^2 + (g - y_0)^2}$$

$$y = y_0 + \frac{k^2(g - y_0)}{(f - x_0)^2 + (g - y_0)^2}.$$

Inverse Function

Given a function $f(x)$, its inverse $f^{-1}(x)$ is defined by

$$f(f^{-1}(x)) = f^{-1}(f(x)) \equiv x.$$

Therefore, $f(x)$ and $f^{-1}(x)$ are reflections about the line $y = x$.

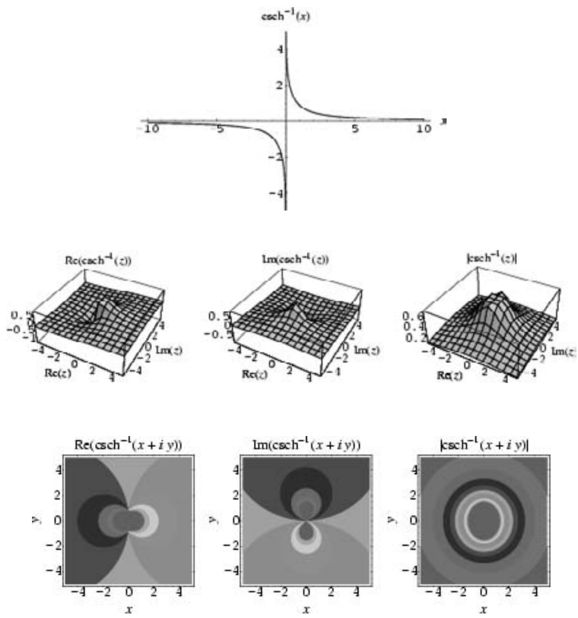
Inverse Function Theorem

Given a smooth function $f : \mathbb{R}^n \to \mathbb{R}^n$, if the Jacobian is invertible at 0, then there is a neighborhood U containing 0 such that $f : U \to f(U)$ is a diffeo-



MORPHISM. That is, there is a smooth inverse $f^{-1}: f(U) \to U$.

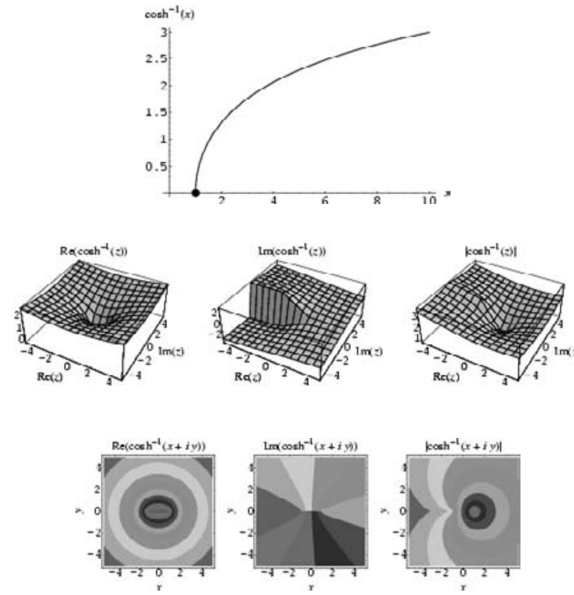
Inverse Hyperbolic Cosecant

The INVERSE FUNCTION of the HYPERBOLIC COSECANT, denoted $\operatorname{csch}^{-1} z$. It can be defined for complex z by

$$\operatorname{csch}^{-1} z = \ln\left(\sqrt{1+\frac{1}{z^2}}+\frac{1}{z}\right), \tag{1}$$

or for real x by

$$\operatorname{csch}^{-1} x = \ln\left(\frac{1 \pm \sqrt{1+x^2}}{x}\right). \tag{2}$$



The inverse hyperbolic cosecant is implemented as `ArcCsch[x]` in *Mathematica*.
The inverse hyperbolic cosecant has TAYLOR SERIES

$$\operatorname{csch}^{-1} x = (\ln 2 - \ln x) + \tfrac{1}{4}x^2 - \tfrac{3}{32}x^4 + \tfrac{5}{96}x^6 + \ldots \tag{3}$$

$$\operatorname{csch}^{-1}\left(\frac{1}{x}\right) = x - \tfrac{1}{6}x^3 + \tfrac{3}{40}x^5 - \tfrac{5}{112}x^7 + \ldots. \tag{4}$$

See also HYPERBOLIC COSECANT, INVERSE HYPERBOLIC FUNCTIONS

Inverse Hyperbolic Cosine

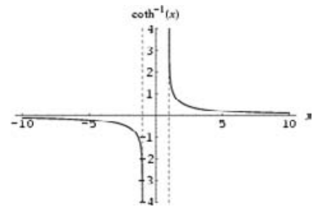
The INVERSE FUNCTION of the HYPERBOLIC COSINE, denoted $\cosh^{-1} z$. It can be defined for complex z by

$$\cosh^{-1} z = \ln\left(z + \sqrt{z+1}\sqrt{z-1}\right), \tag{1}$$

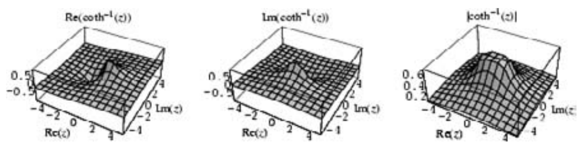
and for real x by

$$\cosh^{-1} x = \ln\left(x \pm \sqrt{x^2-1}\right). \tag{2}$$

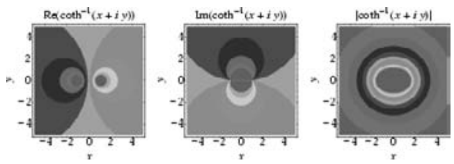
The inverse cosine is implemented as `ArcCosh[x]` in *Mathematica*.



The inverse hyperbolic cosine has the TAYLOR SERIES



$$\cosh^{-1} x = \sqrt{2(x-1)} \times \left[1 - \tfrac{1}{12}(x-1) + \tfrac{3}{160}(x-1)^2 - \tfrac{5}{896}(x-1)^3 + \ldots\right] \tag{3}$$



$$\cosh^{-1}\left(\frac{1}{x}\right) = (\ln 2 - \ln x) - \tfrac{1}{4}x^2 - \tfrac{3}{32}x^4 - \tfrac{5}{96}x^6 + \ldots. \tag{4}$$

See also HYPERBOLIC COSINE, INVERSE HYPERBOLIC FUNCTIONS

Inverse Hyperbolic Cotangent

The INVERSE FUNCTION of the HYPERBOLIC COTANGENT, denoted $\coth^{-1} x$. It can be defined for complex z as

$$\coth^{-1} z = \frac{1}{2}\left[\ln\left(1+\frac{1}{z}\right) - \ln\left(1-\frac{1}{z}\right)\right], \tag{1}$$

and for real x as

$$\coth^{-1} x = \frac{1}{2}\ln\left(\frac{x+1}{x-1}\right). \tag{2}$$

The inverse hyperbolic cotangent is implemented as ArcCoth[x] in *Mathematica*.
It has the special values

$$\coth^{-1} 0 = -\tfrac{1}{2} i\pi \tag{3}$$

$$\coth^{-1} 1 = \infty \tag{4}$$

$$\coth^{-1} \infty = 0. \tag{5}$$

$$\coth^{-1} i = -\tfrac{1}{4}\pi i \tag{6}$$

and the MACLAURIN SERIES

$$\coth^{-1}\left(\frac{1}{x}\right) = x + \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 + \tfrac{1}{7}x^7 + \ldots. \tag{7}$$

See also HYPERBOLIC COTANGENT, INVERSE HYPERBOLIC FUNCTIONS, INVERSE HYPERBOLIC TANGENT

Inverse Hyperbolic Functions

The INVERSE of the HYPERBOLIC FUNCTIONS, denoted $\cosh^{-1} x$, $\coth^{-1} x$, $\operatorname{csch}^{-1} x$, $\operatorname{sech}^{-1} x$, $\sinh^{-1} x$, and $\tanh^{-1} x$. They are defined by

$$\sinh^{-1} z = \ln\left(z + \sqrt{z^2+1}\right) \tag{1}$$

$$\cosh^{-1} z = \ln\left(z \pm \sqrt{z^2-1}\right) \tag{2}$$

$$\tanh^{-1} z = \tfrac{1}{2}\ln\left(\frac{1+z}{1-z}\right) \tag{3}$$

$$\operatorname{csch}^{-1} z = \ln\left(\frac{1 \pm \sqrt{1+z^2}}{z}\right) \tag{4}$$

$$\operatorname{sech}^{-1} z = \ln\left(\frac{1 \pm \sqrt{1+z^2}}{z}\right) \tag{5}$$

$$\coth^{-1} z = \tfrac{1}{2}\ln\left(\frac{z+1}{z-1}\right). \tag{6}$$

Inverse Hyperbolic Secant

The INVERSE FUNCTION of the HYPERBOLIC SECANT,

denoted $\operatorname{sech}^{-1} x$. It can be defined for complex z as

$$\sec^{-1} z = \ln\left(\sqrt{\frac{1}{z}-1}\sqrt{\frac{1}{z}+1}+\frac{1}{z}\right), \tag{1}$$

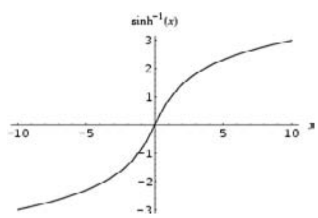
and for real x as

$$\operatorname{sech}^{-1} x = \ln\left(\frac{1 \pm \sqrt{1-x^2}}{x}\right). \tag{2}$$

The inverse hyperbolic secant is implemented as `ArcSech[x]` in *Mathematica*.
It has MACLAURIN SERIES

$$\operatorname{sech}^{-1} x = (\ln 2 - \ln x) - \tfrac{1}{4}x^2 - \tfrac{3}{32}x^4 - \tfrac{5}{96}x^6 - \tfrac{35}{1024}x^8 + \ldots$$

(Sloane's A052468 and A052469) and



$$\operatorname{sech}^{-1}\left(\frac{1}{x}\right) = i\left(\tfrac{1}{2}\pi - x - \tfrac{1}{6}x^3 - \tfrac{3}{40}x^5 + \ldots\right). \tag{3}$$

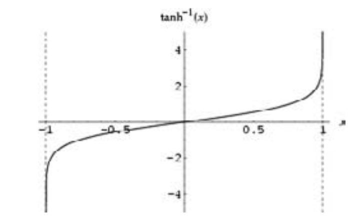
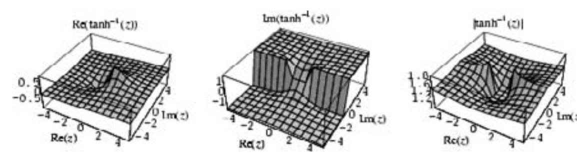
Inverse Hyperbolic Sine

The INVERSE FUNCTION of the HYPERBOLIC SINE, denoted $\sinh^{-1} x$. It can be defined for complex z as

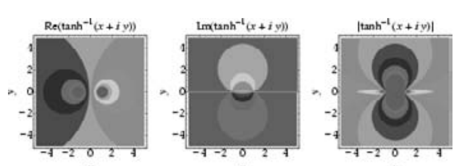
$$\sinh^{-1} z = \ln(z + \sqrt{1+z^2}).$$



The inverse hyperbolic sine is implemented as `ArcSinh[x]` in *Mathematica*.
It has a MACLAURIN SERIES



$$\sinh^{-1} x = x - \tfrac{1}{6}x^3 + \tfrac{3}{40}x^5 - \tfrac{5}{112}x^7 + \tfrac{35}{1152}x^9 + \ldots \tag{1}$$



$$\sinh^{-1}\left(\frac{1}{x}\right) = (\ln 2 - \ln x) + \tfrac{1}{4}x^2 - \tfrac{3}{32}x^4 + \tfrac{5}{96}x^6 - \ldots. \tag{2}$$

See also HYPERBOLIC SINE, INVERSE HYPERBOLIC FUNCTIONS

Inverse Hyperbolic Tangent

The INVERSE FUNCTION of the HYPERBOLIC TANGENT, denoted $\tanh^{-1} x$. It can be defined for complex z as

$$\tanh^{-1} z = \tfrac{1}{2}[\ln(1+z) - \ln(1-z)], \tag{1}$$

and for real x as

$$\tanh^{-1} x = \frac{1}{2}\ln\left(\frac{1+x}{1-x}\right). \tag{2}$$

The inverse hyperbolic tangent is implemented as `ArcTanh[x]` in *Mathematica*.
It has special values

$$\tanh^{-1} 0 = 0 \tag{3}$$

$$\tanh^{-1} 1 = \infty \tag{4}$$

$$\tanh^{-1} \infty = -\tfrac{1}{2}\pi i \tag{5}$$

$$\tanh^{-1} i = \tfrac{1}{4}\pi i \tag{6}$$

and MACLAURIN SERIES

$$\tanh^{-1} x = x + \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 + \tfrac{1}{7}x^7 + \tfrac{1}{9}x^9 + \ldots. \tag{7}$$

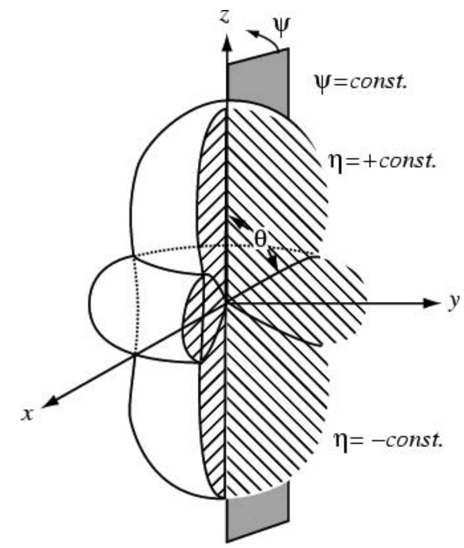
Inverse Nome

Solving the NOME q for the PARAMETER m gives



$$m(q) = \frac{\vartheta_2^4(0, q)}{\vartheta_3^4(0, q)},$$

where $\vartheta_i(z, q)$ is a JACOBI THETA FUNCTION. The inverse nome is implemented as `InverseEllipticNomeQ`[q] in *Mathematica*. It satisfies

$$\lim_{q \to 0+} \frac{dm}{dq} = 16.$$

See also JACOBI THETA FUNCTIONS, NOME

Inverse Oblate Spheroidal Coordinates

A system of coordinates obtained by INVERSION of the oblate spheroids and one-sheeted hyperboloids in OBLATE SPHEROIDAL COORDINATES. The inverse oblate spheroidal coordinates (η, θ, ψ) are given by the transformation equations

$$x = \frac{a \cosh \eta \sin \theta \cos \psi}{\cosh^2 \eta - \cos^2 \theta} \tag{1}$$

$$y = \frac{a \cosh \eta \sin \theta \sin \psi}{\cosh^2 \eta - \cos^2 \theta} \tag{2}$$

$$z = \frac{a \sinh \eta \cos \theta}{\cos^2 \eta - \cos^2 \theta}, \tag{3}$$

where $\eta \geq 0$, $\theta \in [0, \pi]$, and $\psi \in [0, 2\pi)$. Surfaces of constant η are given by the cyclides of rotation

$$x^2 + y^2 + z^2 = a\sqrt{\frac{x^2 + y^2}{\cosh^2 \eta} + \frac{z^2}{\sinh^2 \eta}}, \tag{4}$$

surfaces of constant θ by the cyclides of rotation

$$x^2 + y^2 + z^2 = a\sqrt{\frac{x^2 + y^2}{\sin^2 \theta} - \frac{z^2}{\cos^2 \theta}}, \tag{5}$$

and surfaces of constant ψ by the half-planes

$$\tan \psi = \frac{y}{x}. \tag{6}$$

The metric coefficients are given by

$$g_{\eta\eta} = \frac{a^2(\cosh^2 \eta - \sin^2 \theta)}{(\cosh^2 \eta - \cos^2 \theta)} \quad (7)$$

$$g_{\theta\theta} = \frac{a^2(\cosh^2 \eta - \sin^2 \theta)}{(\cosh^2 \eta - \cos^2 \theta)} \quad (8)$$

$$g_{\psi\psi} = \frac{a^2 \cosh^2 \eta \sin^2 \theta}{(\cosh^2 \eta - \cos^2 \theta)^2}. \quad (9)$$

See also Inverse Prolate Spheroidal Coordinates, Prolate Spheroidal Coordinates

References

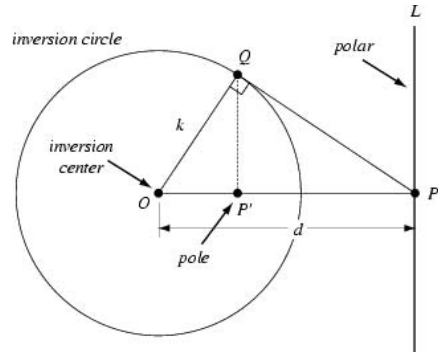
Inverse Permutation

An inverse permutation is a permutation in which each number and the number of the place which it occupies are exchanged. For example,

$$p_1 = \{3, 8, 5, 10, 9, 4, 6, 1, 7, 2\}$$

$$p_2 = \{8, 10, 1, 6, 3, 7, 9, 2, 5, 4\}$$



are inverse permutations, since the positions of 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10 in p_1 are p_2, and the positions of 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10 in p_2 are likewise p_1 (Muir 1960, p. 5). The inverse permutation of a given permutation can be computed using `InversePermutation[p]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``). Inverse permutations are sometimes also called conjugate or reciprocal permutations (Muir 1960, p. 4).

See also Permutation, Permutation Inversion, Self-Conjugate Partition

References

Muir, T. *A Treatise on the Theory of Determinants.* New York: Dover, 1960.

Inverse Points

Points, also called polar reciprocals, which are transformed into each other through inversion about a given inversion circle C (or inversion sphere). The points P and P' are inverse points with respect to the inversion circle if

$$OP \cdot OP' = OQ^2 = k^2$$

(Wenninger 1983, p. 2). In this case, P' is called the pole and the line L through P and perpendicular to OP is called the polar. In the above figure, the quantity k^2 is called the power of the point P relative to the circle C.

The point P' which is the inverse point of a given point P with respect to an inversion circle C may be constructed geometrically using a compass only (Coxeter 1969, p. 78; Courant and Robbins 1996, pp. 144–145).

Inverse points can also be taken with respect to an inversion sphere, which is a natural extension of geometric inversion from the plane to 3-dimensional space.

Inverse Prolate Spheroidal Coordinates

A system of coordinates obtained by INVERSION of the prolate spheroids and two-sheeted hyperboloids in PROLATE SPHEROIDAL COORDINATES. The inverse prolate spheroidal coordinates (η, θ, ψ) are given by the transformation equations

$$x = \frac{a \sinh \eta \sin \theta \cos \psi}{\cosh^2 \eta - \sin^2 \theta} \quad (1)$$

$$y = \frac{a \sinh \eta \sin \theta \sin \psi}{\cosh^2 \eta - \sin^2 \theta} \quad (2)$$

$$z = \frac{a \cosh \eta \cosh \theta}{\cosh^2 \eta - \sin^2 \theta}, \quad (3)$$

with $\eta \geq 0$, $\theta \in [0, \pi]$, and $\psi \in [0, 2\pi)$. Surfaces of constant η are given by the cyclides of rotation

$$x^2 + y^2 + z^2 = a\sqrt{\frac{x^2 + y^2}{\sinh^2 \eta} + \frac{z^2}{\cosh^2 \eta}}, \quad (4)$$

surfaces of constant θ by the cyclides of rotation

$$x^2 + y^2 + z^2 = a\sqrt{-\frac{x^2 + y^2}{\sin^2 \theta} + \frac{z^2}{\cosh^2 \theta}}, \quad (5)$$

and surfaces of constant ψ by the half-planes

$$\tan \psi = \frac{y}{x}. \quad (6)$$

The metric coefficients are given by

$$g_{\eta\eta} = \frac{a^2(\sinh^2 \eta + \sin^2 \theta)}{(\cosh^2 \eta - \sin^2 \theta)^2} \quad (7)$$

$$g_{\theta\theta} = \frac{a^2(\sinh^2 \eta + \sin^2 \theta)}{(\cosh^2 \eta - \sin^2 \theta)^2} \quad (8)$$

$$g_{\psi\psi} = \frac{a^2 \sinh^2 \eta \sinh^2 \theta}{(\cosh^2 \eta - \sin^2 \theta)^2}. \quad (9)$$

Inverse Secant

The function $\sec^{-1} x$, where $\sec x$ is the SECANT and the superscript -1 denotes the INVERSE FUNCTION, *not* the multiplicative inverse. The inverse secant is implemented as `ArcSec[x]` in *Mathematica*. The inverse secant satisfies

$$\sec^{-1} x = \csc^{-1}\left(\frac{x}{\sqrt{x^2-1}}\right) \tag{1}$$

for POSITIVE or NEGATIVE x, and

$$\sec^{-1} x = \pi - \sec^{-1}(-x) \tag{2}$$

for $x \geq 0$. The inverse secant has a TAYLOR SERIES about infinity of

$$\sec^{-1} x = \tfrac{1}{2}\pi - x^{-1} - \tfrac{1}{6}x^{-3} - \tfrac{3}{40}x^{-5} - \tfrac{5}{112}x^{-7} - \ldots. \tag{3}$$

The inverse secant is given in terms of other inverse trigonometric functions by

$$\sec^{-1} x = \cos^{-1}\left(\frac{1}{x}\right) \tag{4}$$

$$= \cot^{-1}\left(\frac{1}{\sqrt{x^2-1}}\right) \tag{5}$$

$$= \tfrac{1}{2}\pi - \csc^{-1} x = -\tfrac{1}{2}\pi = \csc^{-1}(-x) \tag{6}$$

$$= \sin^{-1}\left(\frac{\sqrt{x^2-1}}{x}\right) \tag{7}$$

$$= \tan^{-1}(\sqrt{x^2-1}) \tag{8}$$

for $x \geq 0$.

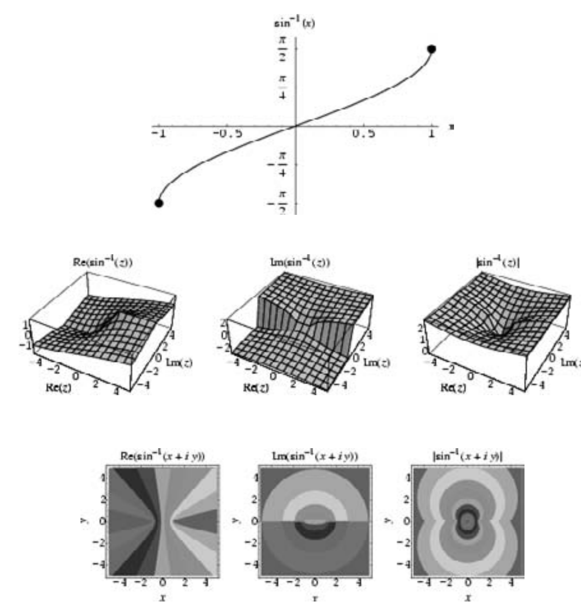
Inverse Semigroup

This entry contributed by NICOLAS BRAY



A SEMIGROUP S is said to be an inverse semigroup if, for every a in S, there is a unique b (called the inverse of a) such that $a = aba$ and $b = bab$. This is equivalent to the condition that every element has at least one inverse and that the IDEMPOTENTS of S COMMUTE (Lawson 1999). Note that if b is an inverse of a, then ba is an IDEMPOTENT.

See also SEMIGROUP

Inverse Sine

The function $\sin^{-1} x$, where $\sin x$ is the SINE and the superscript -1 denotes the INVERSE FUNCTION, *no t* the multiplicative inverse. The notation arcsin x or Arcsin x is sometimes also used. The inverse sine is

implemented as `ArcSin[x]` in *Mathematica*. The inverse sine satisfies

$$\sin^{-1} x = -\sin^{-1}(-x) \tag{1}$$

for POSITIVE and NEGATIVE x, and

$$\sin^{-1} x = \begin{cases} \frac{1}{2}\pi - \sin^{-1}\left(\sqrt{1-x^2}\right) & \text{for } 0 \le x \le 1 \\ -\frac{1}{2}\pi + \sin^{-1}\left(\sqrt{1-x^2}\right) & \text{for } -1 \le x \le 0. \end{cases} \tag{2}$$

The MACLAURIN SERIES for the inverse sine with $-1 \le x \le 1$ is given by

$$\sin^{-1} x = x + \tfrac{1}{6}x^3 + \tfrac{3}{40}x^5 + \tfrac{5}{112}x^7 + \tfrac{35}{1152}x^9 + \ldots. \tag{3}$$

The inverse sine is given in terms of other inverse trigonometric functions by

$$\sin^{-1} x = \cos^{-1}(-x) - \tfrac{1}{2}\pi = \tfrac{1}{2}\pi - \cos^{-1} x \tag{4}$$

$$= \tfrac{1}{2}\pi - \cot^{-1}\left(\frac{x}{\sqrt{1-x^2}}\right) \tag{5}$$

$$= \tan^{-1}\left(\frac{x}{\sqrt{1-x^2}}\right) \tag{6}$$

for POSITIVE or NEGATIVE x, and

$$\sin^{-1} x = \cos^{-1}\left(\sqrt{1-x^2}\right) \tag{7}$$

$$= \cot^{-1}\left(\frac{\sqrt{1-x^2}}{x}\right) \tag{8}$$

$$= \csc^{-1}\frac{1}{x} \tag{9}$$

$$= \sec^{-1}\left(\frac{1}{\sqrt{1-x^2}}\right) \tag{10}$$

for $x \ge 0$.

Inverse Tangent

The inverse tangent is also called the arctangent and is denoted either $\tan^{-1} x$ or arctan x, and is the INVERSE FUNCTION of the TANGENT $\tan x$. The inverse tangent is implemented as `ArcTan[x]` in *Mathematica*.

The ARGUMENT of a COMPLEX NUMBER $z = x + iy$ is often written as

$$\theta = \tan^{-1}\left(\frac{y}{x}\right), \tag{1}$$

where θ, sometimes also denoted ϕ, corresponds to the counterclockwise ANGLE from the POSITIVE REAL AXIS, i.e., the value of θ such that $x = \cos\theta$ and $y = \sin\theta$. This special kind of INVERSE TANGENT takes into account the quadrant in which z lies and is returned by the FORTRAN command `ATAN2(X,Y)` and the *Mathematica* command `ArcTan[x, y]`, and is often restricted to the range $-\pi < \theta \le \pi$. In the degenerate case when $x = 0$,

$$\phi = \begin{cases} -\frac{1}{2}\pi & \text{if } y < 0 \\ \text{undefined} & \text{if } y = 0 \\ \frac{1}{2}\pi & \text{if } y > 0. \end{cases} \tag{2}$$

$\tan^{-1} x$ has the MACLAURIN SERIES for $-1 \le x \le 1$ of

$$\tan^{-1} x = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{2n+1} = x - \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 - \tfrac{1}{7}x^7 + \ldots. \tag{3}$$

A more rapidly converging form due to Euler is given by

$$\tan^{-1} x = \sum_{n=0}^{\infty} \frac{2^{2n}(n!)^2}{(2n+1)!} \frac{x^{2n+1}}{(1+x^2)^{n+1}} \tag{4}$$

(Castellanos 1988).

The inverse tangent satisfies

$$\tan^{-1} x = -\tan^{-1}(-x) \tag{5}$$

for POSITIVE and NEGATIVE x, and

$$\tan^{-1} x = \tfrac{1}{2}\pi - \tan^{-1}\left(\frac{1}{x}\right) \tag{6}$$

for $x \geq 0$. The inverse tangent is given in terms of other inverse trigonometric functions by

$$\tan^{-1} x = \tfrac{1}{2}\pi - \cos^{-1}\left(\frac{x}{\sqrt{x^2+1}}\right) \tag{7}$$

$$= \cot^{-1}(-x) - \tfrac{1}{2}\pi = \tfrac{1}{2}\pi - \cot^{-1} x \tag{8}$$

$$= \sin^{-1}\left(\frac{x}{\sqrt{x^2+1}}\right) \tag{9}$$

for POSITIVE or NEGATIVE x, and

$$\tan^{-1} x = \cos^{-1}\left(\frac{1}{\sqrt{x^2+1}}\right) \tag{10}$$

$$= \cot^{-1}\left(\frac{1}{x}\right) \tag{11}$$

$$= \csc^{-1}\left(\frac{\sqrt{x^2+1}}{x}\right) \tag{12}$$

$$= \sec^{-1}\left(\sqrt{x^2+1}\right) \tag{13}$$

for $x \geq 0$.

In terms of the HYPERGEOMETRIC FUNCTION,

$$\tan^{-1} x = x\, {}_2F_1\left(1, \tfrac{1}{2}; \tfrac{3}{2}; -x^2\right) \tag{14}$$

$$= \frac{x}{1+x^2}\, {}_2F_1\left(1, 1; \tfrac{3}{2}; \frac{x^2}{1+x^2}\right) \tag{15}$$

(Castellanos 1988). Castellanos (1986, 1988) also gives some curious formulas in terms of the FIBONACCI NUMBERS,

$$\tan^{-1} x = \sum_{n=0}^{\infty} \frac{(-1^n) f_{2n+1} t^{2n+1}}{5^n(2n+1)} \tag{16}$$

$$= 5 \sum_{n=0}^{\infty} \frac{(-1)^n f_{2n+1}^2}{(2n+1)\left(u + \sqrt{u^2+1}\right)^{2n+1}} \tag{17}$$

$$= \sum_{n=0}^{\infty} \frac{(-1)^n 5^{n+2} F_{2n+1}^3}{(2n+1)\left(v + \sqrt{v^2+5}\right)^{2n+1}}, \tag{18}$$

where

$$t \equiv \frac{2x}{1 + \sqrt{\frac{4x^2}{5}}} \tag{19}$$

$$u \equiv \frac{5}{4x}\left(1 + \sqrt{1 + \frac{24}{25}x^2}\right), \tag{20}$$

and v is the largest POSITIVE ROOT of

$$8xv^4 - 100v^3 - 450xv^2 + 875v + 625x = 0. \tag{21}$$

The inverse tangent satisfies the addition FORMULA

$$\tan^{-1} x + \tan^{-1} y = \tan^{-1}\left(\frac{x+y}{1-xy}\right) \tag{22}$$

as well as the more complicated FORMULAS

$$\tan^{-1}\left(\frac{1}{a-b}\right) = \tan^{-1}\left(\frac{1}{a}\right) + \tan^{-1}\left(\frac{b}{a^2-ab+1}\right) \tag{23}$$

$$\tan^{-1}\left(\frac{1}{a}\right) = 2\tan^{-1}\left(\frac{1}{2a}\right) - \tan^{-1}\left(\frac{1}{4a^3+3a}\right) \tag{24}$$

$$\tan^{-1}\left(\frac{1}{p}\right) = \tan^{-1}\frac{1}{p+q} + \tan^{-1}\left(\frac{q}{p^2+pq+1}\right), \tag{25}$$

the latter of which was known to Euler. The inverse tangent FORMULAS are connected with many interesting approximations to PI

$$\tan^{-1}(1+x) = \tfrac{1}{4}\pi + \tfrac{1}{2}x - \tfrac{1}{4}x^2 + \tfrac{1}{12}x^3 + \tfrac{1}{40}x^5 + \tfrac{1}{48}x^6 + \tfrac{1}{112}x^7 + \ldots. \tag{26}$$

Euler gave

$$\tan^{-1} x = \frac{y}{x}\left(\frac{2}{3}y + \frac{2\cdot 4}{3\cdot 5}y^2 + \frac{2\cdot 4\cdot 6}{3\cdot 5\cdot 7}y^3 + \ldots\right), \tag{27}$$

where

$$y \equiv \frac{x^2}{1+x^2}. \tag{28}$$

The inverse tangent has CONTINUED FRACTION representations

$$\tan^{-1} x = \cfrac{x}{1 + \cfrac{x^2}{3 + \cfrac{4x^2}{5 + \cfrac{9x^2}{7 + \cfrac{16x^2}{9 + \ldots}}}}} \tag{29}$$

$$= \cfrac{x}{1 + \cfrac{x^2}{3 - x^2 + \cfrac{9x^2}{5 - 3x^2 + \cfrac{25x^2}{7 - 5x^2 + \ldots}}}} \tag{30}$$

To find $\tan^{-1} x$ numerically, the following ARITHMETIC-GEOMETRIC MEAN-like ALGORITHM can be used. Let

$$a_0 = (1 + x^2)^{-1/2} \tag{31}$$

$$b_0 = 1. \tag{32}$$

Then compute

$$a_{i+1} = \tfrac{1}{2}(a_i + b_i) \tag{33}$$

$$b_{i+1} = \sqrt{a_{i+1} b_i}, \tag{34}$$

and the inverse tangent is given by

$$\tan^{-1} x = \lim_{n\to\infty} \frac{x}{\sqrt{1 + x^2} a_n} \tag{35}$$

(Acton 1990).

An inverse tangent $\tan^{-1} n$ with integral n is called reducible if it is expressible as a finite sum OF THE FORM

$$\tan^{-1} n = \sum_{k=1} f_k \tan^{-1} n_k, \tag{36}$$

where f_k are POSITIVE or NEGATIVE INTEGERS and n_i are INTEGERS $< n$. $\tan^{-1} m$ is reducible IFF all the PRIME FACTORS of $1 + m^2$ occur among the PRIME FACTORS of $1 + n^2$ for $n = 1, \ldots, m - 1$. A second NECESSARY and SUFFICIENT condition is that the largest PRIME factor of $1 + m^2$ is less than $2m$. Equivalent to the second condition is the statement that every GREGORY NUMBER $t_x = \cot^{-1} x$ can be uniquely expressed as a sum in terms of t_ms for which m is a STØRMER NUMBER (Conway and Guy 1996). To find this decomposition, write

$$\arg(1 + in) = \arg \prod_{k=1} (1 + n_k i)^{f_k}, \tag{37}$$

so the ratio

$$r = \frac{\prod_{k=1} (1 + n_k i)^{f_k}}{1 + in} \tag{38}$$

is a RATIONAL NUMBER. Equation (38) can also be written

$$r^2 (1 + n^2) = \prod_{k=1} (1 + n_k^2)^{f_k}. \tag{39}$$

Writing (36) in the form

$$\tan^{-1} n = \sum_{k=1} f_k \tan^{-1} n_k + f \tan^{-1} 1 \tag{40}$$

allows a direct conversion to a corresponding INVERSE COTANGENT FORMULA

$$\cot^{-1} n = \sum_{k=1} f_k \cot^{-1} n_k + c \cot^{-1} 1, \tag{41}$$

where

$$c = 2 - f - 2 \sum_{k=1} f_r. \tag{42}$$

Todd (1949) gives a table of decompositions of $\tan^{-1} n$ for $n \le 342$. Conway and Guy (1996) give a similar table in terms of STøRMER NUMBERS.

Arndt and Gosper give the remarkable inverse tangent identity

$$\sin\left(\sum_{k=1}^{2n+1} \tan^{-1} a_k\right) = \frac{(-1)^n}{2n + 1} \frac{\sum_{k=1}^{2n+1} \prod_{j=1}^{2n+1} \left[a_j - \tan\left(\frac{\pi(j-k)}{2n+1}\right)\right]}{\sqrt{\prod_{j=1}^{2n+1} (a_j^2 + 1)}}. \tag{43}$$

Inverse Tangent Integral

The inverse tangent integral $\mathrm{Ti}_2(x)$ is defined in terms of the DILOGARITHM $\mathrm{Li}_2(x)$ by

$$\mathrm{Li}_2(ix) = \tfrac{1}{4}\mathrm{Li}_2(-x^2) + i\ \mathrm{Ti}_2(x) \tag{1}$$

(Lewin 1958, p. 33). It has the series

$$\mathrm{Ti}_2(x) = \sum_{k=1}^{\infty} (-1)^{k-1} \frac{x^{2k-1}}{(2k-1)^2} \tag{2}$$

and gives in closed form the sum

$$\sum_{n=1}^{\infty} \frac{\sin[(4n-2)x]}{(2n-1)^2} = \mathrm{Ti}_2(\tan x) - x \ln(\tan x) \tag{3}$$

that was considered by Ramanujan (Lewin 1958, p. 39). The inverse tangent integral can be expressed in terms of the DILOGARITHM as

$$\mathrm{Ti}_2(x) = \frac{1}{2i}[\mathrm{Li}_2(ix) - \mathrm{Li}_2(-ix)], \tag{4}$$

in terms of LEGENDRE'S CHI-FUNCTION as

$$\mathrm{Ti}_2(x) = -i\chi_2(ix), \tag{5}$$

in terms of the LERCH TRANSCENDENT by

$$\mathrm{Ti}_2(x) = \tfrac{1}{4}x\Phi\left(-x^2, 2, \tfrac{1}{2}\right), \tag{6}$$

and as the integral

$$\mathrm{Ti}_2(x) = \int_0^x \frac{\tan^{-1}(x')}{x'}\,dx'. \tag{7}$$

$\mathrm{Ti}_2(x)$ has derivative

$$\frac{d\mathrm{Ti}_2(x)}{dx} = \frac{\tan^{-1} x}{x}. \tag{8}$$

It satisfies the identities

$$\mathrm{Ti}_2(x) - \mathrm{Ti}_2\left(\frac{1}{x}\right) = \tfrac{1}{2}\pi\ \mathrm{sgn}(x) \ln|x| \tag{9}$$

$$\tfrac{1}{2}\mathrm{Ti}_2\left(\frac{2x}{1-x^2}\right) = \mathrm{Ti}_2(x) + \mathrm{Ti}_2(-x,1) - \mathrm{Ti}_2(x,1), \tag{10}$$

where

$$\mathrm{Ti}_2(x,a) \equiv \int_0^x \frac{\tan^{-1} x'}{a+x'}\,dx' \tag{11}$$

is the generalized inverse tangent function.
$\mathrm{Ti}_2(x)$ has the special value

$$\mathrm{Ti}_2(1) = K, \tag{12}$$

where K is CATALAN'S CONSTANT, and the functional relationships

$$3\ \mathrm{Ti}_2(1) - 2\ \mathrm{Ti}_2\left(\tfrac{1}{2}\right) - \mathrm{Ti}_2\left(\tfrac{1}{3}\right) - \tfrac{1}{2}\mathrm{Ti}_2\left(\tfrac{3}{4}\right) = \tfrac{1}{2}\pi \ln 2, \tag{13}$$

the two equivalent identities

$$3\ \mathrm{Ti}\left(2-\sqrt{3}\right) = 2\ \mathrm{Ti}_2(1) - \tfrac{1}{4}\pi \ln\left(2-\sqrt{3}\right) \tag{14}$$

$$\mathrm{Ti}_2\left(\tan\left(\tfrac{1}{12}\pi\right)\right) = \tfrac{2}{3}\mathrm{Ti}_2\left(\tan\left(\tfrac{1}{4}\pi\right)\right) + \tfrac{1}{12}\pi\ \ln\left(\tan\left(\tfrac{1}{12}\pi\right)\right), \tag{15}$$

and

$$3\ \mathrm{Ti}\left(2+\sqrt{3}\right) = 2\ \mathrm{Ti}_2(1) + \tfrac{5}{4}\pi\ \ln\left(2+\sqrt{3}\right) \tag{16}$$

(Lewin 1958, p. 39). The triplication formula is given by

$$\tfrac{1}{3}\mathrm{Ti}_2\left(\frac{3x-x^3}{1-3x^2}\right) = \mathrm{Ti}_2(x) + \mathrm{Ti}_2\left(\frac{1-x\sqrt{3}}{\sqrt{3}+x}\right) - \mathrm{Ti}_2\left(\frac{1+x\sqrt{3}}{\sqrt{3}-x}\right) + \tfrac{1}{6}\pi\ \ln\left(\frac{(\sqrt{3}+x)(1+x\sqrt{3})}{(1-x\sqrt{3})(\sqrt{3}-x)}\right), \tag{17}$$

which leads to

$$\mathrm{Ti}_2\left(\tan\left(\tfrac{1}{24}\pi\right)\right) - \mathrm{Ti}_2\left(\tan\left(\tfrac{5}{24}\pi\right)\right) + \tfrac{2}{3}\mathrm{Ti}_2\left(\tan\left(\tfrac{1}{8}\pi\right)\right) + \tfrac{1}{6}\pi\ \ln\left(\frac{\tan\left(\frac{5}{24}\pi\right)}{\tan\left(\frac{1}{8}\pi\right)}\right) = 0 \tag{18}$$

and the algebraic form

$$\mathrm{Ti}_2\left(\frac{\sqrt{3}-\sqrt{2}}{\sqrt{2}+1}\right)-\mathrm{Ti}_2\left(\frac{\sqrt{3}-\sqrt{2}}{\sqrt{2}-1}\right)+\tfrac{2}{3}\mathrm{Ti}_2\left(\sqrt{2}-1\right)$$

$$=\tfrac{1}{6}\pi\ \ln\left(\frac{\sqrt{2}-1}{(\sqrt{3}-\sqrt{2})(\sqrt{2}+1)}\right) \quad (19)$$

(Lewin 1958, p. 41).

Inverse Trigonometric Functions

Inverse functions of the trigonometric functions written $\cos^{-1} x$, $\cot^{-1} x$, $\csc^{-1} x$, $\sec^{-1} x$, $\sin^{-1} x$, and $\tan^{-1} x$. As noted by Feynman (1997), the notation $f^{-1}x$ is unfortunate because it conflicts with the common interpretation of a superscripted quantity as indicating a power, i.e., $f^{-1}x=(1/f)x=x/f$.

The inverse trigonometric functions are generally defined on the following domains.

Function	Domain
$\sin^{-1} x$	$-\tfrac{1}{2}\pi \le y \le \tfrac{1}{2}\pi$
$\cos^{-1} x$	$0 \le y \le \pi$
$\tan^{-1} x$	$-\tfrac{1}{2}\pi < y < \tfrac{1}{2}\pi$
$\csc^{-1} x$	$0 \le y \le \tfrac{1}{2}\pi$ or $\pi \le y \le \frac{3\pi}{2}$
$\sec^{-1} x$	$0 \le y \le \pi$
$\cot^{-1} x$	$0 \le y \le \tfrac{1}{2}\pi$ or $-\pi \le y \le -\tfrac{1}{2}\pi$

Inverse-forward identities are

$$\tan^{-1}(\cot x)=\tfrac{1}{2}\pi-x \quad (1)$$

$$\sin^{-1}(\cos x)=\tfrac{1}{2}\pi-x \quad (2)$$

$$\sec^{-1}(\csc x)=\tfrac{1}{2}\pi-x, \quad (3)$$

and forward-inverse identities are

$$\cos(\sin^{-1} x)=\sqrt{1-x^2} \quad (4)$$

$$\cos(\tan^{-1} x)=\frac{1}{\sqrt{1+x^2}} \quad (5)$$

$$\sin(\cos^{-1} x)=\sqrt{1-x^2} \quad (6)$$

$$\sin(\tan^{-1} x)=\frac{x}{\sqrt{1+x^2}} \quad (7)$$

$$\tan(\cos^{-1} x)=\frac{\sqrt{1-x^2}}{x} \quad (8)$$

$$\tan(\sin^{-1} x)=\frac{x}{\sqrt{1-x^2}}. \quad (9)$$

Inverse sum identities include

$$\sin^{-1} x+\cos^{-1} x=\tfrac{1}{2}\pi \quad (10)$$

$$\tan^{-1} x+\cot^{-1} x=\tfrac{1}{2}\pi \quad (11)$$

$$\sec^{-1} x+\csc^{-1} x=\tfrac{1}{2}\pi, \quad (12)$$

where (10) follows from

$$x=\sin(\sin^{-1} x)=\cos\left(\tfrac{1}{2}\pi-\sin^{-1} x\right). \quad (13)$$

Complex inverse identities in terms of logarithms include

$$\sin^{-1}(z)=-i\ \ln\left(iz\pm\sqrt{1-z^2}\right) \quad (14)$$

$$\cos^{-1}(z)=-i\ \ln\left(z\pm i\sqrt{1-z^2}\right) \quad (15)$$

$$\tan^{-1}(z)=-i\ \ln\left(\frac{1+iz}{\sqrt{1+z^2}}\right) \quad (16)$$

$$=\tfrac{1}{2}i\ \ln\left(\frac{1-iz}{1+iz}\right). \quad (17)$$

Inversely Proportional

Two quantities y and x are said to be inversely proportional (or "in inverse proportion") if y is given by a constant multiple of $1/x$, i.e., $y = c/x$ for c a constant. This relationship is commonly written $y \propto x^{-1}$.

See also DIRECTLY PROPORTIONAL, PROPORTIONAL

Inversely Similar

inversely similar

Two figures are said to be SIMILAR when all corresponding ANGLES are equal, and are inversely similar when all corresponding ANGLES are equal and described in the opposite rotational sense.

WEIERSTRASS ELLIPTIC FUNCTION

Inversion

Inversion is the process of transforming points P to a corresponding set of points P' known as their INVERSE POINTS. Two points P and P' are said to be inverses with respect to an INVERSION CIRCLE having INVERSION CENTER $O = (x_0, y_0)$ and INVERSION RADIUS k if P' is the foot of the altitude of ΔOQP, where Q is a point on the circle such that $OQ \perp PQ$. The analogous notation of inversion can be carried to in 3-dimensional space with respect to an INVERSION SPHERE.

If P and P' are inverse points, then the line L through P and perpendicular to OP is sometimes called a "POLAR" with respect to point P, known as the "POLE". In addition, the curve to which a given curve is transformed under inversion is called its INVERSE CURVE (or more simply, its "inverse"). This sort of inversion was first systematically investigated by Jakob Steiner.

From similar triangles, it immediately follows that the inverse points P and P' obey

$$\frac{OP}{k} = \frac{k}{OP'}, \tag{1}$$

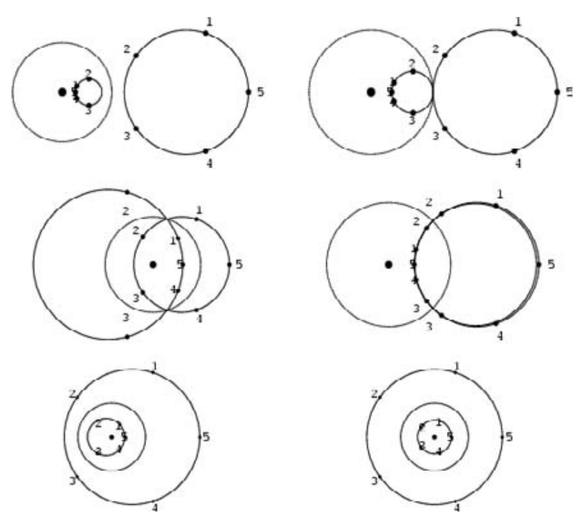
or

$$k^2 = OP \times OP' \tag{2}$$

(Coxeter 1969, p. 78), where the quantity k^2 is known as the POWER (Coxeter 1969, p. 81).

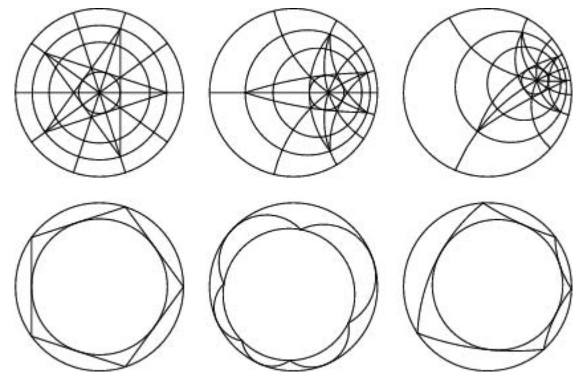
The general equation for the inverse of the point (x, y) relative to the INVERSION CIRCLE with INVERSION

CENTER (x_0, y_0) and INVERSION RADIUS k is given by



$$x' = x_0 + \frac{k^2(x - x_0)}{(x - x_0)^2 + (y - y_0)^2} \tag{3}$$

$$y' = y_0 + \frac{k^2(y - y_0)}{(x - x_0)^2 + (y - y_0)^2}. \tag{4}$$



In vector form,

$$\mathbf{x}' = \mathbf{x}_0 + \frac{k^2(\mathbf{x} - \mathbf{x}_0)}{|\mathbf{x} - \mathbf{x}_0|^2}. \tag{5}$$

Note that a point on the CIRCUMFERENCE of the INVERSION CIRCLE is its own inverse point. In addition, any ANGLE inverts to an opposite ANGLE.

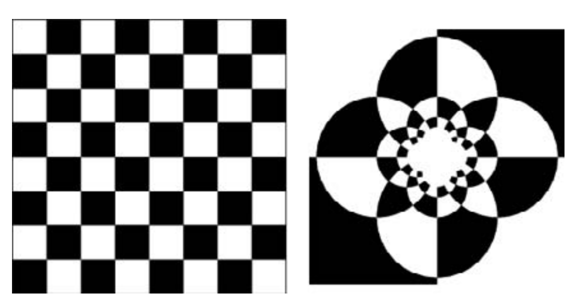
Treating LINES as CIRCLES of INFINITE RADIUS, all CIRCLES invert to CIRCLES (Lachlan 1893, p. 221). Furthermore, any two nonintersecting circles can be inverted into concentric circles by taking the INVERSION CENTER at one of the two so-called LIMITING POINTS of the two circles (Coxeter 1969), and any two circles can be inverted into themselves or into two equal circles (Casey 1888, pp. 97–98). ORTHOGONAL CIRCLES invert to ORTHOGONAL CIRCLES (Coxeter 1969). The INVERSION CIRCLE itself, circles orthogonal to it, and lines through the INVERSION CENTER are invariant under inversion. Furthermore, inversion is a CONFORMAL MAP, so angles are preserved.

The property that inversion transforms circles and lines to circles or lines (and that inversion is conformal) makes it an extremely important tool of plane analytic geometry. By picking a suitable inversion circle, it is often possible to transform one geometric configuration into another simpler one in which a proof is more easily effected. The illustration above shows examples of the results of geometric inversion.

The inverse of a CIRCLE of RADIUS a with CENTER (x, y) with respect to an inversion circle with INVERSION CENTER (x_0, y_0) and INVERSION RADIUS k is another CIRCLE with CENTER

$$x' = x_0 + s(x - x_0) \tag{6}$$

$$y' = y_0 + s(y - y_0) \tag{7}$$



and RADIUS

$$r' = |s|a, \tag{8}$$

where

$$s \equiv \frac{k^2}{(x - x_0)^2 + (y - y_0)^2 - a^2}. \tag{9}$$

These equations can also be naturally extended to inversion with respect to a sphere in 3-dimensional space.

The above plot shows a CHESSBOARD centered at (0, 0) and its inverse about a small circle also centered at (0, 0) (Gardner 1984, pp. 244–245; Dixon 1991).

Inversion Center

The point that INVERSION OF A CURVE is performed with respect to.

See also INVERSE POINTS, INVERSION CIRCLE, INVERSION RADIUS, INVERSIVE DISTANCE, LIMITING POINT, POLAR, POLE (INVERSION), POWER (CIRCLE)

Inversion Circle

The CIRCLE with respect to which an INVERSE CURVE is computed or relative to which INVERSE POINTS are computed. In 3-D, INVERSE POINTS can be computed relative to an INVERSION SPHERE.

See also INVERSE POINTS, INVERSION CENTER, INVERSION RADIUS, INVERSION SPHERE, INVERSIVE DISTANCE, MIDCIRCLE, POLAR, POLE (INVERSION), POWER (CIRCLE)

Inversion Number

In DETERMINANT EXPANSION BY MINORS, the minimal number of TRANSPOSITIONS of adjacent columns in a SQUARE MATRIX needed to turn the matrix representing a permutation of $\{1, 2, \ldots, n\}$ into the IDENTITY MATRIX.

See also DETERMINANT EXPANSION BY MINORS, TRANSPOSITION

References

Inversion Operation

The SYMMETRY OPERATION $(x, y, z) \to (-x, -y, -z)$. When used in conjunction with a ROTATION, it becomes an IMPROPER ROTATION.

Inversion Poset

A relation between permutations p and q that exists if there is a sequence of TRANSPOSITIONS such that each transposition increases the number of inversions (Stanton and White 1986; Skiena 1990, p. 162).

See also PERMUTATION

Inversion Radius

The RADIUS used in performing an INVERSION with respect to an INVERSION CIRCLE.

See also INVERSE POINTS, INVERSION CENTER, INVERSION CIRCLE, INVERSIVE DISTANCE, POLAR, POLE (INVERSION), POWER (CIRCLE)

Inversion Semigroup

INVERSE SEMIGROUP

Inversion Sphere

The SPHERE with respect to which INVERSE POINTS are computed (i.e., with respect to which geometrical INVERSION is performed). For example, the CYCLIDES are inversions in a sphere of TORI. The center of the inversion sphere is called the INVERSION CENTER, and its radius is called the INVERSION RADIUS. When DUAL POLYHEDRA are being considered, the inversion sphere is commonly called the MIDSPHERE (or intersphere, or reciprocating sphere).

In 2-D, the inversion sphere collapses to an INVERSION CIRCLE.

See also CYCLIDE, INVERSE POINTS, INVERSION, INVERSION CENTER, INVERSION CIRCLE, INVERSION RADIUS, INVERSIVE DISTANCE, MIDCIRCLE, MIDSPHERE, POLAR, POLE (INVERSION), POWER (CIRCLE)

Inversion Statistic

Inversion Vector

The number of elements greater than i to the left of i in a PERMUTATION gives the ith element of the inversion vector (Skiena 1990, p. 27). A PERMUTATION p can be converted to an inversion vector using `ToInversionVector[p]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``), and an inversion vector v can be converted to a PERMUTATION using `ToInversionVector[v]`.

Inversive Distance

The inversive distance is the NATURAL LOGARITHM of the ratio of two concentric circles into which the given circles can be inverted. Let c be the distance between the centers of two nonintersecting CIRCLES of RADII a and $b<a$. Then the inversive distance is

$$\delta = \cosh^{-1}\left|\frac{a^2+b^2-c^2}{2ab}\right|$$

(Coxeter and Greitzer 1967).

The inversive distance between the SODDY CIRCLES is given by

$$\delta = 2\cosh^{-1} 2,$$

and the CIRCUMCIRCLE and INCIRCLE of a TRIANGLE with CIRCUMRADIUS R and INRADIUS r are at inversive distance

$$\delta = 2\sinh^{-1}\left(\frac{1}{2}\sqrt{\frac{r}{R}}\right)$$

(Coxeter and Greitzer 1967, pp. 130–131).

Invertible Knot

A knot which can be deformed via an AMBIENT ISOTOPY into itself but with the orientation reversed. No noninvertible knots were known until Trotter (1964) discovered an infinite family, the smallest of which had nine crossings. The simplest noninvertible knot is 08–017, illustrated above. The following table gives the numbers of noninvertible and invertible knots of n crossings.

type	Sloane	counts
noninvertible	A052403	0, 0, 0, 0, 0, 0, 0, 1, 2, 33, 187, 1144, 6919, 38118, 226581, 1309875, ...
invertible	A052402	0, 0, 1, 1, 2, 3, 7, 20, 47, 132, 365, 1032, 3069, 8854, 26712, 78830, ...

No general technique is known for determining if a KNOT is invertible. Burde and Zieschang (1985) give a tabulation from which it is possible to extract the noninvertible knots up to 10 crossings.

Invertible Linear Map

An invertible linear transformation $T: V \to W$ is a map between VECTOR SPACES V and W with an inverse map which is also a LINEAR TRANSFORMATION. When T is given by MATRIX MULTIPLICATION, i.e., $T(v) = \mathsf{A}v$, then T is invertible IFF A is a INVERTIBLE MATRIX. Note that the dimensions of V and W must be the same.

See also INVERTIBLE MATRIX, LINEAR TRANSFORMATION, MATRIX, VECTOR SPACE

Invertible Linear Transformation

INVERTIBLE LINEAR MAP

Invertible Matrix

NONSINGULAR MATRIX

Invertible Polynomial Map

A POLYNOMIAL MAP $\phi_{\mathbf{f}}$, with $\mathbf{f} = (f_1, \ldots, f_n) \in (K[X_1, \ldots, X_n])^m$ in a FIELD K is called invertible if there exist $g_1, \ldots, g_m \in K[X_1, \ldots, x_n]$ such that $g_i(f_1, \ldots, f_n) = X_i$ for $1 \leq n \leq n$ so that $\phi_{\mathbf{g}} \circ \phi_{\mathbf{f}} = \mathrm{id}_{k^n}$ (Becker and Weispfenning 1993, p. 330). GRÖBNER BASES provide a means to decide for given $\mathbf{f}$ whether or not $\phi_{\mathbf{f}}$ is invertible.

See also JACOBIAN CONJECTURE, POLYNOMIAL MAP

References

Becker, T. and Weispfenning, V. *Gröbner Bases: A Computational Approach to Commutative Algebra.* New York: Springer-Verlag, p. 330, 1993.

Involuntary

A LINEAR TRANSFORMATION of period two. Since a LINEAR TRANSFORMATION has the form,

$$\lambda' = \frac{\alpha\lambda + \beta}{\gamma\lambda + \delta}, \tag{1}$$

applying the transformation a second time gives

$$\lambda'' + \frac{\alpha\lambda' + \beta}{\gamma\lambda' + \delta} = \frac{(\alpha^2 + \beta\gamma)\lambda + \beta(\alpha + \delta)}{(\alpha + \delta)\gamma\lambda + \beta\gamma + \delta^2}, \tag{2}$$

For an involuntary, $\lambda'' = \lambda$, so

$$\gamma(\alpha+\delta)\lambda^2+(\delta^2-\alpha^2)\lambda-(\alpha+\delta)\beta=0. \quad (3)$$

Since each COEFFICIENT must vanish separately,

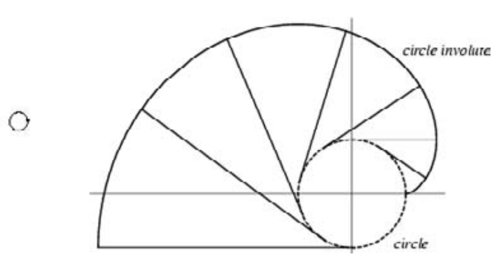
$$\alpha\gamma+\gamma\delta=0 \quad (4)$$

$$\delta^2-\alpha^2=0 \quad (5)$$

$$\alpha\beta+\beta\delta=0. \quad (6)$$

The first equation gives $\delta=\pm\alpha$. Taking $\delta=\alpha$ would require $\gamma=\beta=0$, giving $\lambda=\lambda'$, the identity transformation. Taking $\delta=-\alpha$ gives $\delta=-\alpha$, so

$$\lambda'=\frac{\alpha\lambda+\beta}{\gamma\lambda-\alpha} \quad (7)$$



the general form of an INVOLUTION.

See also CROSS-RATIO, INVOLUTION (LINE)

Involute

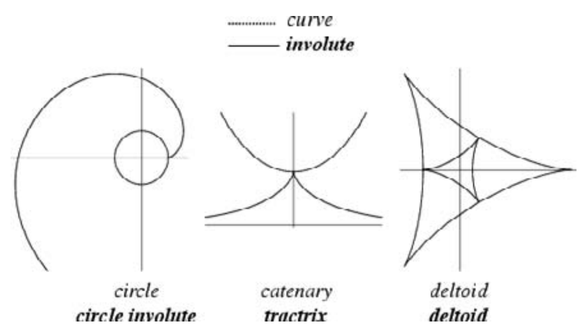
Attach a string to a point on a curve. Extend the string so that it is tangent to the curve at the point of attachment. Then wind the string up, keeping it always taut. The LOCUS of points traced out by the end of the string is the involute of the original curve, and the original curve is called the EVOLUTE of its involute. Although a curve has a unique EVOLUTE, it has infinitely many involutes corresponding to different choices of initial point. An involute can also be thought of as any curve ORTHOGONAL to all the TANGENTS to a given curve.

The equation of the involute is

$$\mathbf{r}_i=\mathbf{r}-s\hat{\mathbf{T}}, \quad (1)$$

where $\hat{\mathbf{T}}$ is the TANGENT VECTOR

$$\hat{\mathbf{T}}=\frac{\frac{d\mathbf{r}}{dt}}{\left|\frac{d\mathbf{r}}{dt}\right|} \quad (2)$$



and s is the ARC LENGTH

$$s=\int ds=\int\frac{ds}{dt}dt=\int\frac{\sqrt{ds^2}}{dt}dt=\int\sqrt{f'^2+g'^2}\,dt. \quad (3)$$

This can be written for a parametrically represented function $(f(t), g(t))$ as

$$x(t)=f-\frac{sf'}{\sqrt{f'^2+g'^2}} \quad (4)$$

$$y(t)=g-\frac{sg'}{\sqrt{f'^2+g'^2}}. \quad (5)$$

The following table lists the involutes of some common curves, some of which are illustrated above.

Curve	Involute
ASTROID	ASTROID 1/2 as large
CARDIOID	CARDIOID 3 times as large
CATENARY	TRACTRIX
CIRCLE CATACAUSTIC for a point source	LIMAÇON
CIRCLE	CIRCLE INVOLUTE (a SPIRAL)
CYCLOID	equal CYCLOID
DELTOID	DELTOID 1/3 as large
ELLIPSE	ELLIPSE INVOLUTE
EPICYCLOID	reduced EPICYCLOID
HYPOCYCLOID	similar HYPOCYCLOID
LOGARITHMIC SPIRAL	equal LOGARITHMIC SPIRAL
NEILE'S PARABOLA	PARABOLA
NEPHROID	CAYLEY'S SEXTIC
NEPHROID	NEPHROID 2 times as large

Involution

An OPERATOR of period 2, i.e., an OPERATOR $*$ which satisfies $((a)^*)^* = a$.

Involution (Group)

An element of order 2 in a GROUP (i.e., an element A of a GROUP such that $A^2 = I$, where I is the IDENTITY ELEMENT).

See also GROUP, IDENTITY ELEMENT

Involution (Line)

Pairs of points of a line, the product of whose distances from a FIXED POINT is a given constant. This is more concisely defined as a PROJECTIVITY of period two.

If $\{AA', BB', CC'\}$ is a range in involution, then the ranges $\{AA', BC\}$ and $\{A'A, B'C'\}$ are EQUICROSS, and conversely.

See also EQUICROSS, INVOLUTORY

Involution (Operator)

An OPERATOR of period 2, i.e., an OPERATOR $\bar{3}$ which satisfies

$$\sin^{-1} x = x + \tfrac{1}{6}x^3 + \tfrac{3}{40}x^5 + \tfrac{5}{112}x^7 + \tfrac{35}{1152}x^9 + \ldots.$$

Involution (Permutation)

An involution of a SET S is a PERMUTATION of S which does not contain any CYCLES of length > 2 (i.e., it consists exclusively of fixed points and TRANSPOSITIONS). Involutions are in one-to-one correspondence with self-conjugate permutations (i.e, permutations that are their own INVERSE PERMUTATION). For example, the unique permutation involution on 1 element is $\{1\}$, the two involution permutations on 2 elements are $\{1,2\}$ and $\{2,1\}$, and the four involution permutations on 3 elements are $\{1,2,3\}$, $\{1,3,2\}$, $\{2,1,3\}$, and $\{3,2,1\}$. A PERMUTATION p can be tested to determine if it is a permutation using `InvolutionQ[p]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

The PERMUTATION MATRICES of an involution are SYMMETRIC. The number of involutions on n elements is the same as the number of distinct YOUNG TABLEAUX on n elements (Skiena 1990, p. 32).

In general, the number of involution permutations on n letters is given by the formula

$$I(n) = 1 + \sum_{k=0}^{\lfloor (n-2)/2 \rfloor} \frac{1}{(k+1)!} \binom{n-2i}{2}, \tag{1}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT (Muir 1960, p. 5), or alternatively by

$$I(n) = n! \sum_{k=0}^{\lfloor n \rfloor} \frac{1}{2^k k!(n-2k)!} \tag{2}$$

(Skiena 1990, p. 32). Although the number of involutions on n symbols cannot be expressed as a fixed number of hypergeometric terms (Petkovsek *et al.* 1996, p. 160), it can be written in terms of the CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND $U(a,b,z)$ as

$$I(n) = (-i)^n 2^{n/2} U\left(-\tfrac{1}{2}n, \tfrac{1}{2}, -\tfrac{1}{2}\right). \tag{3}$$

Breaking this up into n even and odd gives

$$I(n) = \begin{cases} (-2)^k U\left(-k, \tfrac{1}{2}, -\tfrac{1}{2}\right) & \text{for } n = 2k \\ (-2)^k U\left(-k, \tfrac{3}{2}, -\tfrac{1}{2}\right) & \text{for } n = 2k+1 \end{cases} \tag{4}$$

The number of involutions $I(n)$ of a SET containing the first n integers is given by the RECURRENCE RELATION

$$I(n) = I(n-1) + (n-1)I(n-2) \tag{5}$$

(Muir 1960, pp. 3–7; Skiena 1990, p. 32). For $n = 1, 2, \ldots$, the first few values of $I(n)$ are 1, 2, 4, 10, 26, 76, ... (Sloane's A000085).

Involution (Transformation)

A TRANSFORMATION of period 2.

Involution Principle

GARSIA-MILNE INVOLUTION PRINCIPLE

Involutory

A LINEAR TRANSFORMATION of period two. Since a LINEAR TRANSFORMATION has the form,

$$\lambda' = \frac{\alpha\lambda + \beta}{\gamma\lambda + \delta}, \tag{1}$$

applying the transformation a second time gives

$$\lambda'' = \frac{\alpha\lambda' + \beta}{\gamma\lambda' + \delta} = \frac{(\alpha^2 + \beta\gamma)\lambda + (\beta\alpha + \delta)}{(\alpha + \delta)\gamma\lambda + \beta\gamma + \delta^2}. \tag{2}$$

For an involutory, $\lambda'' = \lambda$, so

$$\gamma(\alpha + \delta)\lambda^2 + (\delta^2 - \alpha^2)\lambda - (\alpha + \delta)\beta = 0. \tag{3}$$

Since each COEFFICIENT must vanish separately,

$$\gamma(\alpha + \delta) = 0 \tag{4}$$

$$\delta^2 - \alpha^2 = 0 \tag{5}$$

$$\beta(\alpha + \delta) = 0. \tag{6}$$

Equation (5) requires $\delta = \pm\alpha$. Taking $\delta = \alpha$ in turn requires that $\gamma = \beta = 0$, giving $\lambda = \lambda'$, i.e., the IDENTITY MAP, while taking $\delta = -\alpha$ gives $\delta = -\alpha$, so

$$\lambda' = \frac{\alpha\lambda + \beta}{\gamma\lambda - \alpha}, \tag{7}$$

which is the general form of an INVOLUTION.

Irradiation Illusion

The ILLUSION shown above which was discovered by Helmholtz in the 19th century. Despite the fact that the two above figures are identical in size, the white hole looks bigger than the black one in this ILLUSION.

See also ILLUSION

References

Pappas, T. "Irradiation Optical Illusion." *The Joy of Mathematics.* San Carlos, CA: Wide World Publ./Tetra, p. 199, 1989.

Irrational Number

A number which cannot be expressed as a FRACTION p/q for any INTEGERS p and q. The most famous irrational number is $\sqrt{2}$, sometimes called PYTHAGORAS'S CONSTANT. Legend has it that the Pythagorean philosopher Hippasus used geometric methods to demonstrate the irrationality of $\sqrt{2}$ while at sea and, upon notifying his comrades of his great discovery, was immediately thrown overboard by the fanatic Pythagoreans . Other examples include $\sqrt{3}$, e, π, etc.

Every TRANSCENDENTAL NUMBER is irrational. Numbers OF THE FORM $n^{1/m}$ are irrational unless n is the mth POWER of an INTEGER. Numbers OF THE FORM $\log_n m$, where log is the LOGARITHM, are irrational if m and n are INTEGERS, one of which has a PRIME factor which the other lacks. e^r is irrational for rational $r \neq 0$. $\cos r$ is irrational for every nonnegative rational number r (Niven 1956, Stevens 1999), and $\cos(\theta)$ (for θ measured in degrees) is irrational for every rational $0° < \theta < 90°$ with the exception of $\theta = 60°$ (Niven 1956). $\tan r$ is irrational for every rational $r \neq 0$ (Stevens 1999).

The irrationality of E was proven by Lambert in 1761; for the general case, see Hardy and Wright (1979,

p. 46). π^n is irrational for POSITIVE integral n. The irrationality of PI itself was proven by Lambert in 1760; for the general case, see Hardy and Wright (1979, p. 47). APÉRY'S CONSTANT $\zeta(3)$ (where $\zeta(z)$ is the RIEMANN ZETA FUNCTION) was proved irrational by Apéry (Apéry 1979, van der Poorten 1979). In addition, T. Rivoal (2000) recently proved that there are infinitely many integers n such that $\zeta(2n+1)$ is irrational.

From GELFOND'S THEOREM, a number OF THE FORM a^b is TRANSCENDENTAL (and therefore irrational) if a is ALGEBRAIC $\neq 0$, 1 and b is irrational and ALGEBRAIC. This establishes the irrationality of e^π (since $(-1)^{-i} = (e^{i\pi})^{-i} = e^\pi$)), $2^{\sqrt{2}}$, and $e\pi$. Nesterenko (1996) proved that $\pi + e^\pi$ is irrational. In fact, he proved that π, e^π and $\Gamma(1/4)$ are ALGEBRAICALLY INDEPENDENT, but it was not previously known that $\pi + e^\pi$ was irrational.

Given a POLYNOMIAL equation

$$x^m + c_{m-1}x^{m-1} + \ldots + c_0, \tag{1}$$

where c_i are INTEGERS, the roots x_i are either integral or irrational. If $\cos(2\theta)$ is irrational, then so are $\cos\theta$, $\sin\theta$, and $\tan\theta$.

Irrationality has not yet been established for 2^e, π^e, $\pi^{\sqrt{2}}$, or γ (where γ is the EULER-MASCHERONI CONSTANT).

QUADRATIC SURDS are irrational numbers which have periodic CONTINUED FRACTIONS.

HURWITZ'S IRRATIONAL NUMBER THEOREM gives bounds OF THE FORM

$$\left|\alpha - \frac{p}{q} < \frac{1}{l_n q^2}\right| \tag{2}$$

for the best rational approximation possible for an arbitrary irrational number α, where the l_n are called LAGRANGE NUMBERS and get steadily larger for each "bad" set of irrational numbers which is excluded.

The SERIES

$$\sum_{n=1}^{\infty} \frac{\sigma_k(n)}{n!}, \tag{3}$$

where $\sigma_k(n)$ is the DIVISOR FUNCTION, is irrational for $k=1$ and 2, and the series

$$\sum_{n=1}^{\infty} \frac{1}{2^n - 1} = \sum_{n=1}^{\infty} \frac{d(n)}{2^n}, \tag{4}$$

where $d(n)$ is the number of divisors of n, is also irrational (Guy 1994).

Irrationality Measure

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let x be a REAL NUMBER, and let R be the SET of POSITIVE REAL NUMBERS for which

$$\left|x - \frac{p}{q}\right| < q^{-r} \tag{1}$$

has (at most) finitely many solutions p/q for p and q INTEGERS. Then the irrationality measure, sometimes called the Liouville-Roth constant, is defined as the threshold at which LIOUVILLE'S APPROXIMATION THEOREM kicks in and x is no longer approximable by RATIONAL NUMBERS,

$$r(x) \equiv \inf_{r \in R} r. \tag{2}$$

There are three regimes:

$$\begin{cases} r(x)=1 & x \text{ is rational} \\ r(x)=2 & x \text{ is algebraic} \\ r(x)\geq 3 & x \text{ is transcendental} \end{cases} \quad (3)$$

Exact values include

$$r(L)=\infty$$

$$r(e)=2,$$

where L is LIOUVILLE'S CONSTANT. The best known upper bounds for other common constants are summarized in the following table, where $\zeta(3)$ is APÉRY'S CONSTANT, $Ln_q(2)$ and $h_q(1)$ are Q-HARMONIC SERIES, and the lower bounds are 2.

constant x	upper bound	reference
π	8.0161	Hata (1992)
π^2	6.3489	Hata (1992)
ln 2	4.13	
$\zeta(3)$	7.377956	Hata (2000)
$Ln_q(2)$	4.80	Amdeberhan and Zeilberger (1998)
$h_q(1)$	4.80	Amdeberhan and Zeilberger (1998)

Irrationality Sequence

A sequence of POSITIVE INTEGERS $\{a_n\}$ such that $\Sigma\, 1/(a_n b_n)$ is IRRATIONAL for all integer sequences $\{b_n\}$. Erdos showed that $\{2^{2^n}\}=\{1,2,4,16,256,\ldots,\}$ (Sloane's A001146) is an irrationality sequence.

Irreducible Matrix

A SQUARE MATRIX which is not REDUCIBLE is said to be irreducible.

See also REDUCIBLE MATRIX

Irreducible Polynomial

A POLYNOMIAL is said to be irreducible if it cannot be factored into nontrivial polynomials over the same FIELD.

For example, in the FIELD of rational polynomials $\mathbb{Q}[x]$ (i.e., polynomials $f(x)$ with rational coefficients), a $f(x)$ is said to be irreducibility if there do not exist two nonconstant polynomials $g(x)$ and $h(x)$ in x with rational coefficients such that

$$f(x)=g(x)h(x)$$

(Nagell 1951, p. 160). Similarly, in the FINITE FIELD GF(2), x^2+x+1 is irreducible, but x^2+1 is not, since $(x+1)(x+1)=x^2+2x+1\equiv x^2+1 \pmod 2$. A polynomial can be tested to see if it is primitive using the *Mathematica* function

```
IrreducibleQ[p_,n_] := SameQ[Factor[p, Modulus->n], p]
```

In general, the number of irreducible polynomials of degree n over the FINITE FIELD GF(q) is given by

$$L_q(n)=\frac{1}{n}\sum_{d|n}\mu\left(\frac{n}{d}\right)q^d,$$

where $\mu(n)$ is the MÖBIUS FUNCTION.

The number of irreducible polynomials of degree n over GF(2) is equal to the number of n-bead fixed aperiodic NECKLACES of two colors and the number of binary LYNDON WORDS of length n. The first few values for $n=1$, 2, ... are 2, 1, 2, 3, 6, 9, 18, ... (Sloane's A001037). The following table lists the irreducible polynomials (mod 2) of degrees 1 through 5.

n	irreducible polynomials
1	$1, x$
2	$1+x+x^2$
3	$1+x+x^3$, $1+x^2+x^3$
4	$1+x+x^4$, $1+x+x^2+x^3+x^4$, $1+x^3+x^4$
5	$1+x^2+x^5$, $1+x+x^2+x^3+x^5$, $1+x^3+x^5$, $1+x+x^3+x^4+x^5$, $1+x^2+x^3+x^4+x^5$, $1+x+x^2+x^4+x^5$

Irreducible Representation

An irreducible representation of a GROUP is a REPRESENTATION that has no nontrivial invariant subspaces. For example, the ORTHOGONAL GROUP $O(n)$ has an irreducible representation on $\mathbb{R}^n$.

Any representation of a finite or SEMISIMPLE LIE GROUP breaks up into a DIRECT SUM of irreducible representations. But in general, this is not the case, e.g., $(\mathbb{R},+)$ has a representation on $\mathbb{R}^2$ by

$$\phi(a)=\begin{bmatrix}1 & a\\ 0 & 1\end{bmatrix},$$

i.e., $\phi(a)(x,y)=(x+ay,y)$. But the subspace $y=0$ is fixed, hence ϕ is not irreducible, but there is no complementary invariant subspace.

The irreducible representation has a number of remarkable properties, as formalized in the GROUP ORTHOGONALITY THEOREM. Let the ORDER of a GROUP be h, and the dimension of the ith representation (the order of each constituent matrix) be l_i (a POSITIVE INTEGER). Let any operation be denoted R, and let the mth row and nth column of the matrix corresponding to a matrix R in the ith IRREDUCIBLE REPRESENTATION be $\Gamma_i(R)_{mn}$. The following properties can be derived from the GROUP ORTHOGONALITY THEOREM,

$$\sum_R \Gamma_i(R)_{mn}\Gamma_j(R)^*_{m'n'}=\frac{h}{\sqrt{l_i l_j}}\delta_{ij}\delta_{mm'}\delta_{nn'}. \quad (1)$$

1. The DIMENSIONALITY THEOREM:

$$h=\sum_i l_i^2=l_1^2+l_2^2+l_3^2+\ldots=\sum_i \chi_i^2(I), \quad (2)$$

where each l_i must be a POSITIVE INTEGER and χ is the CHARACTER (trace) of the representation.

2. The sum of the squares of the CHARACTERS in any IRREDUCIBLE REPRESENTATION i equals h,

$$h=\sum_R \chi_i^2(R). \quad (3)$$

3. ORTHOGONALITY of different representations

$$\sum_R \chi_i(R)\chi_i(R)=0 \quad \text{for } i\neq j. \quad (4)$$

4. In a given representation, reducible or irreducible, the CHARACTERS of all MATRICES belonging to operations in the same class are identical (but differ from those in other representations).

5. The number of IRREDUCIBLE REPRESENTATIONS of a GROUP is equal to the number of CONJUGACY CLASSES in the GROUP. This number is the dimension of the Γ MATRIX (although some may have zero elements).

6. A one-dimensional representation with all 1s (totally symmetric) will always exist for any GROUP.

7. A 1-D representation for a GROUP with elements expressed as MATRICES can be found by taking the CHARACTERS of the MATRICES.

8. The number a_i of IRREDUCIBLE REPRESENTATIONS χ_i present in a reducible representation c is given by

$$a_i=\frac{1}{h}\sum_R \chi(R)\chi_i(R), \quad (5)$$

where h is the ORDER of the GROUP and the sum must be taken over all elements in each class. Written explicitly,

$$a_i=\frac{1}{h}\sum_R \chi(R)\chi_i'(R)n_R, \quad (6)$$

where χ_i' is the CHARACTER of a single entry in the CHARACTER TABLE and n_R is the number of elements in the corresponding CONJUGACY CLASS.

Irreducible representations can be indicated using MULLIKEN SYMBOLS.

Irreducible Semiperfect Number

PRIMITIVE PSEUDOPERFECT NUMBER

Irreducible Tensor

Given a general second RANK TENSOR A_{ij} and a METRIC g_{ij}, define

$$\theta \equiv A_{ij} g^{ij} = A_i^i \quad (1)$$

$$\omega^i \equiv \epsilon^{ijk} A_{jk} \quad (2)$$

$$\sigma_{ij} \equiv \tfrac{1}{2}(A_{ij} + A_{ji}) - \tfrac{1}{3} g_{ij} A_k^k, \quad (3)$$

where δ_{ij} is the KRONECKER DELTA and ϵ^{ijk} is the LEVI-CIVITA SYMBOL. Then

$$\begin{aligned}&\sigma_{ij} + \tfrac{1}{3}\theta g_{ij} + \tfrac{1}{2}\epsilon_{ijk}\omega^k \\ &= \left[\tfrac{1}{2}(A_{ij} + A_{ji}) - \tfrac{1}{3} g_{ij} A_k^k\right] + \tfrac{1}{3} A_k^k g_{ij} + \tfrac{1}{2}\epsilon_{ijk}\left[\epsilon^{\lambda\mu k} A_{\lambda\mu}\right] \\ &= \tfrac{1}{2}(A_{ij} + A_{ji}) + \tfrac{1}{2}\left(\delta_i^\lambda \delta_j^\mu - \delta_i^\mu \delta_j^\lambda\right) A_{\lambda\mu} \\ &= \tfrac{1}{2}(A_{ij} + A_{ji}) + \tfrac{1}{2}(A_{ij} - A_{ji}) = A_{ij}, \quad (4)\end{aligned}$$

where θ, ω^i, and σ_{ij} are TENSORS of RANK 0, 1, and 2.

Irreducible Variety

An ALGEBRAIC VARIETY is called irreducible if it cannot be written as the union of nonempty algebraic varieties. For example, the set of solutions to $xy = 0$ is reducible because it is the union of the solutions to $x = 0$ and the solutions to $y = 0$.

See also ALGEBRAIC SET, ALGEBRAIC VARIETY, PROJECTIVE VARIETY

Irredundant Ramsey Number

Let G_1, G_2, ..., G_t be a t-EDGE coloring of the COMPLETE GRAPH K_n, where for each $i = 1, 2, \ldots, t$, G_i is the spanning SUBGRAPH of K_n consisting of all EDGES colored with the ith color. The irredundant Ramsey number $s(q_1, \ldots, q_t)$ is the smallest INTEGER n such that for any t-EDGE coloring of K_n, the COMPLEMENT GRAPH $\overline{G_i}$ has an irredundant set of size q_i for at least one $i = 1, \ldots, t$. Irredundant Ramsey numbers were introduced by Brewster *et al.* (1989) and satisfy

$$s(q_1, \cdots q_t) \leq R(q_1, \ldots q_t).$$

For a summary, see Mynhardt (1992).

Irreflexive

A RELATION R on a SET S is irreflexive provided that no element is related to itself; in other words, xRx for no x in S.

See also RELATION

Irregular Pair

If p divides the NUMERATOR of the BERNOULLI NUMBER B_{2k} for $0 < 2k < p-1$, then $(p, 2k)$ is called an irregular pair. For $p < 30000$, the irregular pairs of various forms are $p = 16843$ for $(p, p-3)$, $p = 37$ for $(p, p-5)$, none for $(p, p-7)$, and $p = 67,877$ for $(p, p-9)$.

Irregular Prime

PRIMES for which Kummer's theorem on the unsolvability of FERMAT'S LAST THEOREM does not apply. An irregular prime p divides the NUMERATOR of one of the BERNOULLI NUMBERS $B_0, B_2, \ldots, B_{p-3}$, as shown by Kummer in 1850. The FERMAT EQUATION has no solutions for REGULAR PRIMES.

An INFINITE number of irregular primes exist, as proven in 1915 by Jensen. The first few irregular primes are 37, 59, 67, 101, 103, 131, 149, 157, ... (Sloane's A000928). Of the 283,145 PRIMES less than 4×10^6, 111,597 (or 39.41%) are irregular. The conjectured FRACTION is $1 - e^{-1/2} \approx 39.35\%$ (Ribenboim 1996, p. 415).

Irregular Singularity

Consider a second-order ORDINARY DIFFERENTIAL EQUATION

$$y'' + P(x)y' + Q(x)y = 0.$$

If $P(x)$ and $Q(x)$ remain FINITE at $x = x_0$, then x_0 is called an ORDINARY POINT. If either $P(x)$ or $Q(x)$ diverges as $x \to x_0$, then x_0 is called a singular point. If $P(x)$ diverges more quickly than $1/(x - x_0)$, so $(x - x_0)P(x)$ approaches INFINITY as $x \to x_0$, or $Q(x)$ diverges more quickly than $1/(x - x_0)^2 Q$ so that $(x - x_0)^2 Q(x)$ goes to INFINITY as $x \to x_0$, then x_0 is called an IRREGULAR SINGULARITY (or ESSENTIAL SINGULARITY).

Wiley	0–471

The International Standard Book Number (ISBN) is a 10-digit CODE which is used to uniquely identify a book. The digits d_i are arranged in four groups, which are sometimes (but not always) separated by hyphens. The first group is a single digit which codes country or language in which a publisher is incorporated: 0 for English, 2 for French, 3 for German, 4 for Japanese, 8 for Indian publishers, etc. The next group of digits specifies the publisher, and may range in length from two to seven digits, with fewer digits used for larger publishers. Some publishers with offices in more than one country (at least when different languages are spoken in those countries) have multiple publisher codes and initial digits.

The third group of digits specifies an individual book, and may be from one to six digits in length. The actual number is eight minus the number of digits in the publisher group, so that small publishers may have only 10 books, while large ones can have up to a millions books. The last digit d_{10} is a check digit which may be in the range 0–9 or X (where X is the ROMAN NUMERAL for 10). The check digit is computed from the equation

$$10d_1 + 9d_2 + 8d_3 + \ldots + 2d_9 + d_{10} \equiv 0 \pmod{11}.$$

For example, the number for this book is 0–8493–9640–9, and

$$10\cdot 0 + 9\cdot 8 + 8\cdot 4 + 7\cdot 9 + 6\cdot 3 + 5\cdot 9$$

$$+4\cdot 6 + 3\cdot 4 + 2\cdot 0 + 1\cdot 9 = 275 = 25\cdot 11 \equiv 0 \pmod{11}.$$

as required.

The ISBN is error-detecting, but not error-correcting (unless it is known that only a single digit is erroneous). The ISBN detects any single-digit error, as well as any two-digit error resulting from transposing two digits.

Iseki's Formula

Let $\Re[z] > 0$, $0 \leq \alpha, \beta \leq 1$, and

$$\Lambda(\alpha, \beta, z) \equiv \sum_{r=0}^{\infty} [\lambda((r+\alpha)z - i\beta) + \lambda((r+1-\alpha)z + i\beta)], \quad (1)$$

where

$$\lambda(x) \equiv -\ln\left(1 - e^{-2\pi x}\right) = \sum_{m=1}^{\infty} \frac{e^{-2\pi m x}}{m}. \quad (2)$$

Then if either $0 \leq \alpha \leq 1$ and $0 < \beta < 1$, or $0 < \alpha < 1$ and $0 \leq \beta \leq 1$,

$$\Lambda(\alpha, \beta, z)$$

$$= \Lambda\left(1-\beta, \alpha, z^{-1}\right) - \pi z \sum_{n=0}^{2} \binom{2}{n} (iz)^{-n} B_{2-n}(\alpha) B_n(\beta), \quad (3)$$

where $B_k(x)$ is a BERNOULLI POLYNOMIAL, and the second term on the right side can be written explicitly as

$$-\pi z\left(\alpha^2\alpha + \tfrac{1}{6}\right) + \frac{\pi}{z}\left(\beta^2 - \beta + \tfrac{1}{6}\right) + 2\pi i\left(\alpha - \tfrac{1}{2}\right)(\beta - h). \quad (4)$$

SIGNATURE (RECURRENCE RELATION)

Island

If an integrable QUASIPERIODIC system is slightly perturbed so that it becomes nonintegrable, only a finite number of n-CYCLES remain as a result of MODE LOCKING. One will be elliptical and one will be hyperbolic.

Surrounding the ELLIPTIC FIXED POINT is a region of stable ORBITS which circle it, as illustrated above in the STANDARD MAP with $K=1.5$. As the map is iteratively applied, the island is mapped to a similar structure surrounding the next point of the elliptic cycle. The map thus has a chain of islands, with the FIXED POINT alternating between ELLIPTIC (at the center of the islands) and HYPERBOLIC (between islands). Because the unperturbed system goes through an INFINITY of rational values, the perturbed system must have an INFINITE number of island chains.

Isodynamic Points

The first and second isodynamic points of a TRIANGLE ΔABC can be constructed by drawing the triangle's ANGLE BISECTORS and EXTERIOR ANGLE BISECTORS. Each pair of bisectors intersects a side of the triangle (or its extension) in two points D_{i1} and D_{i2}, for $i = 1, 2, 3$. The three CIRCLES having $D_{11}D_{12}$, $D_{21}D_{22}$, and $D_{31}D_{32}$ as DIAMETERS are the APOLLONIUS CIRCLES C_1, C_2, and C_3. The points S and S' in which the three APOLLONIUS CIRCLES intersect are the first and second isodynamic points, respectively.

S and S' have TRIANGLE CENTER FUNCTIONS

$$\alpha = \sin\left(A \pm \tfrac{1}{3}\pi\right),$$

respectively. The ANTIPEDAL TRIANGLES of both points are EQUILATERAL and have AREAS

$$\Delta' = 2\Delta\left[\cot\omega \cot\left(\tfrac{1}{3}\pi\right)\right],$$

where ω is the BROCARD ANGLE.

The isodynamic points are ISOGONAL CONJUGATES of the FERMAT POINTS. They lie on the BROCARD AXIS. The distances from either isodynamic point to the VERTICES are inversely proportional to the sides. The PEDAL TRIANGLE of either isodynamic point is an EQUILATERAL TRIANGLE. An INVERSION with either isodynamic point as the INVERSION CENTER transforms the triangle into an EQUILATERAL TRIANGLE.

The CIRCLE which passes through both the isodynamic points and the CENTROID of a TRIANGLE is known as the PARRY CIRCLE.

Isoenergetic Nondegeneracy

The condition for isoenergetic nondegeneracy for a Hamiltonian

$$H = H_0(\mathbf{I}) + \epsilon H_1(\mathbf{I}, \boldsymbol{\theta})$$

is

$$\begin{vmatrix} \dfrac{\partial^2 H_0}{\partial I_i \partial I_j} & \dfrac{\partial H_0}{\partial I_i} \\ \dfrac{\partial H_0}{\partial I_j} & 0 \end{vmatrix} \neq 0,$$

which guarantees the EXISTENCE on every energy level surface of a set of invariant tori whose complement has a small MEASURE.

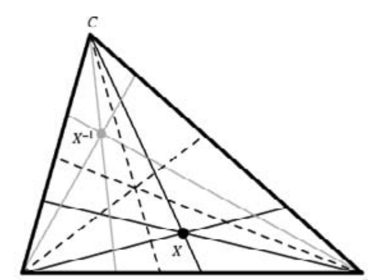
Isogeny



A rational homomorphism $\varphi G \to G'$ defined over a FIELD is called an isogeny when $\dim G = \dim G'$. Two GROUPS G and G' are then called isogenous if there exists a third group G'' and isogenies $G'' \to G$ and $G'' \to G'$.

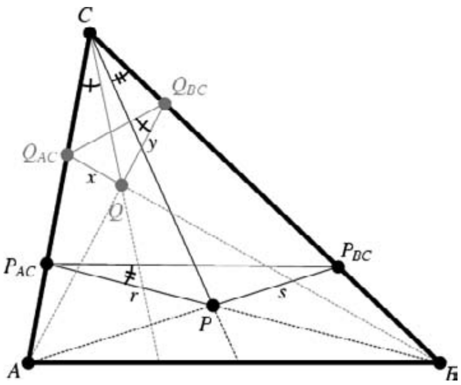
Isogonal Conjugate



The isogonal conjugate X^{-1} of a point X in the plane of the TRIANGLE ΔABC is constructed by reflecting the lines AX, BX, and CX about the ANGLE BISECTORS at A, B, and C. The three reflected lines then CONCUR at the isogonal conjugate (Honsberger 1995, pp. 55–56). The TRILINEAR COORDINATES of the isogonal conjugate of the point with coordinates

$$\alpha : \beta : \gamma$$

are

$$\alpha^{-1} : \beta^{-1} : \gamma^{-1}.$$

In the above figure with P and Q isogonal conjugates,

$$\frac{x}{y} = \frac{s}{r} \tag{1}$$

(Honsberger 1995, pp. 54–55).

Isogonal conjugation maps the interior of a TRIANGLE onto itself. This mapping transforms lines onto CONIC SECTIONS that CIRCUMSCRIBE the TRIANGLE. The type of CONIC SECTION is determined by whether the line d meets the CIRCUMCIRCLE C',

1. If d does not intersect C', the isogonal transform is an ELLIPSE;
2. If d is tangent to C', the transform is a PARABOLA;
3. If d cuts C', the transform is a HYPERBOLA, which is a RECTANGULAR HYPERBOLA if the line passes through the CIRCUMCENTER

(Casey 1893, Vandeghen 1965).

The isogonal conjugate of a point on the CIRCUMCIRCLE is a POINT AT INFINITY (and conversely). The sides of the PEDAL TRIANGLE of a point are PERPENDICULAR to the connectors of the corresponding VERTICES with the isogonal conjugate. The isogonal conjugate of a set of points is the LOCUS of their isogonal conjugate points.

The product of ISOTOMIC and isogonal conjugation is a COLLINEATION which transforms the sides of a TRIANGLE to themselves (Vandeghen 1965).

Isogonal Line

The line L' through a TRIANGLE VERTEX obtained by reflecting an initial line L (also through a VERTEX) about the ANGLE BISECTOR. If three lines from the VERTICES of a TRIANGLE ΔABC are CONCURRENT at $X = L_1L_2L_3$, then their isogonal lines are also CONCURRENT, and the point of concurrence $X' = L'_1L'_2L'_3$ is called the ISOGONAL CONJUGATE point.

Isogonic Centers

FERMAT POINTS

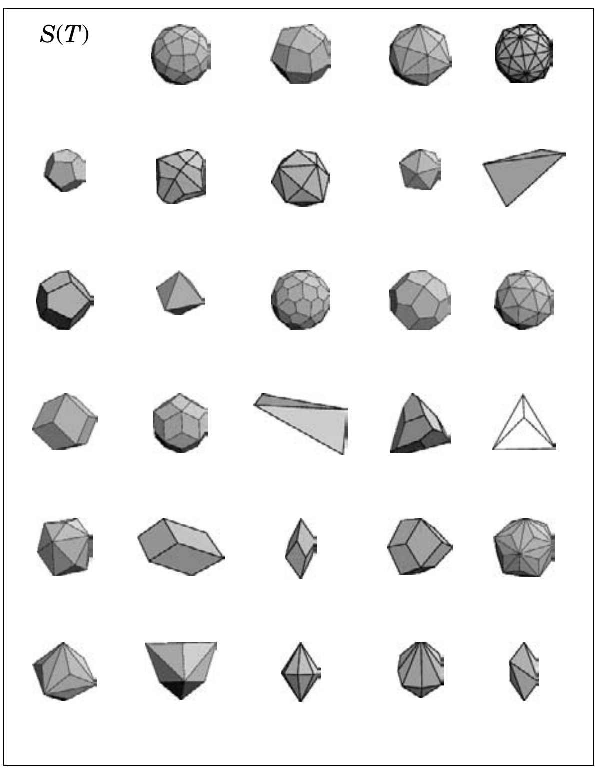
Isograph

The substitution of $re^{i\theta}$ for z in a POLYNOMIAL $p(z)$. $p(z)$ is then plotted as a function of θ for a given r in the COMPLEX PLANE. By varying r so that the curve passes through the ORIGIN, it is possible to determine a value for one ROOT of the POLYNOMIAL.

Isohedral Tiling

Let $S(T)$ be the group of symmetries which map a MONOHEDRAL TILING T onto itself. The TRANSITIVITY

CLASS of a given tile T is then the collection of all tiles to which T can be mapped by one of the symmetries of $S(T)$. If T has k TRANSITIVITY CLASSES, then T is said to be k-isohedral. Berglund (1993) gives examples of k-isohedral tilings for $k = 1$, 2, and 4.



See also ANISOHEDRAL TILING

Isohedron

A convex POLYHEDRON with symmetries acting transitively on its faces. Every isohedron has an EVEN number of faces (Grünbaum 1960). The isohedra make fair DICE, and there are 30 of them, many of which are PLATONIC SOLIDS, ARCHIMEDEAN SOLIDS, or duals of ARCHIMEDEAN SOLIDS.

The 30 isohedra are the CUBE, DISDYAKIS DODECAHEDRON, DELTOIDAL HEXECONTAHEDRON, DELTOIDAL ICOSITETRAHEDRON, DISDYAKIS TRIACONTAHEDRON, DODECAHEDRON, dyakis dodecahedron, hexakis tetrahedron, ICOSAHEDRON, isosceles tetrahedron, octahedral pentagonal dodecahedron, OCTAHEDRON, PENTAGONAL HEXECONTAHEDRON, PENTAGONAL ICOSITETRAHEDRON, PENTAKIS DODECAHEDRON, RHOMBIC DODECAHEDRON, RHOMBIC TRIACONTAHEDRON, scalene tetrahedron, tetragonal pentagonal dodecahedron, TETRAHEDRON, TETRAKIS HEXAHEDRON, trapezoidal dihedron, trapezoidal dihedron (skewed), trapezoidal dodecahedron, TRIAKIS ICOSAHEDRON, TRIAKIS OCTAHEDRON, TRIAKIS TETRAHEDRON, triangular dihedron, triangular dihedron (skewed in-out), triangular dihedron (skewed up-down).

A 2-D LAMINA such as a COIN can also be viewed as a degenerate case of a fair 2-sided solid.

Isolated Point

An isolated point on a curve, also known as an ACNODE or HERMIT POINT, is a point which has no other points in its NEIGHBORHOOD.

An isolated point of a GRAPH is a node of degree 1 (Harary 1994, p. 15). The number of n-node graphs with no isolated points are 0, 1, 2, 7, 23, 122, 888, ... (Sloane's A002494), the first few of which are illustrated below.

An isolated point of a DISCRETE SET S is a member of S (Krantz 1999, p. 63).

Isolated Singular Point

ISOLATED SINGULARITY

Isolated Singularity

An isolated singularity is a SINGULARITY for which there exists a (small) REAL NUMBER ϵ such that there are no other SINGULARITIES within a NEIGHBORHOOD of radius ϵ centered about the SINGULARITY. Isolated singularities are also known as conic double points.

The types of isolated singularities possible for CUBIC SURFACES have been classified (Schläfli 1864, Cayley 1869, Bruce and Wall 1979) and are summarized in the following table from Fischer (1986).

Name	Symbol	Normal Form	COXETER DIAGRAM
conic double point	C_2	$x^2+y^2+z^2$	A_1
biplanar double point	B_3	$x^2+y^2+z^3$	A_2
biplanar double point	B_4	$x^2+y^2+z^4$	A_3
biplanar double point	B_5	$x^2+y^2+z^5$	A_4
biplanar double point	B_6	$x^2+y^2+z^6$	A_5
uniplanar double point	U_6	$x^2+z(y^2+z^2)$	D_4
uniplanar double point	U_7	$x^2+z(y^2+z^3)$	D_5
uniplanar double point	U_8	$x^2+y^3+z^4$	E_6
elliptic cone point	–	$xy^2-4z^3-g_2x^2y+g_3x^3$	$\tilde{E}_6$

Isolating Integral

An integral of motion which restricts the PHASE SPACE available to a DYNAMICAL SYSTEM.

Isometric

A METRIC SPACE X is isometric to a METRIC SPACE Y if there is a BIJECTION f between X and Y that preserves distances. That is, $d(a,b)=d(f(a),f(b))$. In the context of RIEMANNIAN GEOMETRY, two manifolds M and N are isometric if there is a DIFFEOMORPHISM such that the RIEMANNIAN METRIC from one pulls back to the metric on the other. Since the GEODESICS define a distance, a RIEMANNIAN METRIC makes the MANIFOLD M a METRIC SPACE. An isometry between Riemannian manifolds is also an isometry between the two manifolds, considered as metric spaces.

Isometric spaces are considered isomorphic. For instance, the circle of radius one around the origin is isometric to the circle of radius one around $(0,3)$.

See also ISOMETRIC LATITUDE, ISOMETRY, METRIC SPACE, RIEMANNIAN METRIC, TOPOLOGICAL SPACE

Isometric Latitude

An AUXILIARY LATITUDE which is directly proportional to the spacing of parallels of LATITUDE from the equator on an ellipsoidal MERCATOR PROJECTION. It is defined by

$$\psi = \ln\left|\tan\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\phi\right)\left(\frac{1 - e\sin\phi}{1 + e\sin\phi}\right)^{e/2}\right|, \qquad (1)$$

where the symbol τ is sometimes used instead of ψ. The isometric latitude is related to the CONFORMAL LATITUDE by

$$\psi = \ln\tan\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\chi\right). \qquad (2)$$

The inverse is found by iterating

$$\phi = 2\tan^{-1}\left[\exp(\psi)\left(\frac{1 + e\sin\phi}{1 - e\sin\phi}\right)^{e/2}\right] - \tfrac{1}{2}\pi, \qquad (3)$$

with the first trial as

$$\phi_0 = 2\tan^{-1}(e^{\psi}) - \tfrac{1}{2}\pi. \qquad (4)$$

Isometry

A BIJECTIVE MAP between two METRIC SPACES that preserves distances, i.e.,

$$d(f(x), f(y)) = d(x, y),$$

where f is the MAP and $d(a, b)$ is the DISTANCE function. Isometries are sometimes also called congruence transformations. Two figures that can be transformed into each other by an isometry are said to be CONGRUENT (Coxeter and Greitzer 1967, p. 80).

An isometry of the PLANE is a linear transformation which preserves length. Isometries include ROTATION, TRANSLATION, REFLECTION, GLIDES, and the IDENTITY MAP. If an isometry has more than one FIXED POINT, it must be either the identity transformation or a reflection. Every isometry of period two (two applications of the transformation preserving lengths in the original configuration) is either a reflection or a half-turn rotation. Every isometry in the plane is the product of at most three reflections (at most two if there is a FIXED POINT). Every finite group of isometries has at least one FIXED POINT.

Isomorphic

The term "isomorphic" means "having the same form," and is used in many branches of mathematics to identify mathematical objects which have the same structural properties. Objects which may be represented (or "embedded") differently but which have the same essential structure are often said to be "identical up to an isomorphism." The statement "A is isomorphic to B" is denoted $A \cong B$ (Harary 1994, p. 161).

References

Harary, F. *Graph Theory.* Reading, MA: Addison-Wesley, 1994.

Isomorphic Graphs

Two GRAPHS which contain the same number of VERTICES connected in the same way are said to be isomorphic. Formally, two graphs G and H with VERTICES $V_n = \{1, 2, \ldots, n\}$ are said to be isomorphic if there is a PERMUTATION p of V_n such that $\{u, v\}$ is in the set of EDGES $E(G)$ IFF $\{p(u), p(v)\}$ is in the set of EDGES $E(H)$.

Determining if two GRAPHS are isomorphic is thought to be an NP-HARD PROBLEM (Skiena 1990, p. 181), although this has not been proved. However, a polynomial-time algorithm is known when the maximum VERTEX DEGREE is bounded by a constant (Luks 1980; Skiena 1990, p. 181). The equivalence or nonequivalence of two graphs can be ascertained using `IsomorphicQ[`*g1*`, `*g2*`]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Isomorphic Groups

Two GROUPS are isomorphic if the correspondence between them is ONE-TO-ONE and the "multiplication" table is preserved. For example, the POINT GROUPS C_2 and D_1 are isomorphic GROUPS, written $C_2 \cong D_1$ or $C_2 \rightleftharpoons D_1$ (Shanks 1993).

See also JORDAN-HÖLDER THEOREM

References
Shanks, D. *Solved and Unsolved Problems in Number Theory, 4th ed.* New York: Chelsea, 1993.

Isomorphic Posets

Two POSETS are said to be isomorphic if their "structures" are entirely analogous. Formally, POSETS $P = (X, \leq)$ and $Q = (X, \leq')$ are isomorphic if there is a BIJECTION f from X to X' such that $x \leq x'$ precisely when $f(x) \leq' f(x')$.

Isomorphism

Isomorphism is a very general concept which appears in several areas of mathematics. The word derives from the Greek $\iota\sigma o$ (*iso*), meaning "equal," and $\mu o\rho\varphi\omega\sigma\iota\varsigma$ (*morphosis*), meaning "to form" or "to shape." Formally, an isomorphism is BIJECTIVE MORPHISM. Informally, an isomorphism is a map which preserves sets and relations among elements. "A is isomorphic to B" is written $A \cong B$. Unfortunately, this symbol is also used to denote geometric CONGRUENCE.

A space isomorphism is a VECTOR SPACE in which addition and scalar multiplication are preserved. An isomorphism of a TOPOLOGICAL SPACE is called a HOMEOMORPHISM.

Two groups G_1 and G_2 with binary operators $+$ and $\times$ are isomorphic if there exists a map $f : G_1 \to G_2$ which satisfies

$$f(x+y) = f(x) \times f(y).$$

An isomorphism preserves the identities and inverses of a GROUP. An isomorphism of a GROUP onto itself is called an AUTOMORPHISM.

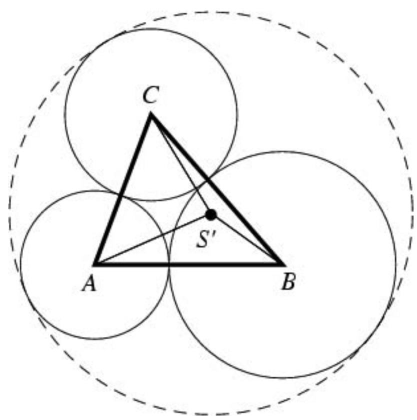
Isoperimetric Inequality

Let a PLANE figure have AREA A and PERIMETER p. Then



$$Q \equiv \frac{4\pi A}{p^2} \leq 1,$$

where Q is known as the ISOPERIMETRIC QUOTIENT. The equation becomes an EQUALITY only for a CIRCLE.

See also ISOPERIMETRIC QUOTIENT

References

Isoperimetric Point

The point S' which makes the PERIMETERS of the TRIANGLES $\Delta BS'C$, $\Delta CS'A$, and $\Delta AS'B$ equal. The isoperimetric point exists IFF the largest ANGLE of the triangle satisfies

$$\max(A, B, C) < 2\sin^{-1}\left(\tfrac{4}{5}\right) \approx 1.85459 \text{ rad} \approx 106.26°,$$

or equivalently

$$a + b + c > 4R + r,$$

where a, b, and c are the side lengths of ΔABC, r is the INRADIUS, and R is the CIRCUMRADIUS. The isoperimetric point is also the center of the outer SODDY CIRCLE of ΔABC and has TRIANGLE CENTER

FUNCTION

$$\alpha = 1 - \frac{2\Delta}{a(b+c-a)} = \sec\left(\tfrac{1}{2}A\right)\cos\left(\tfrac{1}{2}B\right)\cos\left(\tfrac{1}{2}C\right) - 1.$$

Isoperimetric Problem

Find a closed plane curve of a given PERIMETER which encloses the greatest AREA. The solution is a CIRCLE. If the class of curves to be considered is limited to smooth curves, the isoperimetric problem can be stated symbolically as follows: find an arc with PARAMETRIC EQUATIONS $x = x(t)$, $y = y(t)$ for $t \in |t_1, t_2|$ such that $x(t_1) = x(t_2)$, $y(t_1) = y(t_2)$ (where no further intersections occur) constrained by

$$l = \int_{t_1}^{t_2} \left(\sqrt{x'^2 + y'^2}\right) dt$$

such that

$$A = \tfrac{1}{2}\int_{t_1}^{t_2} (xy' - x'y)\, dt$$

is a MAXIMUM.

Zenodorus proved that the AREA of the CIRCLE is larger than that of any POLYGON having the same PERIMETER, but the problem was not rigorously solved until Steiner published several proofs in 1841 (Wells 1991).

Isoperimetric Quotient

Portions of this entry contributed by HERMANN KREMER

The isoperimetric quotient of a closed curve is defined as the ratio of the curve area to the area of a circle with same perimeter as the curve,

$$Q \equiv \frac{4\pi A}{p^2}, \tag{1}$$

where A is the area of the plane figure and p is its PERIMETER. The ISOPERIMETRIC INEQUALITY gives $Q \leq 1$, with equality only in the case of the CIRCLE.

For a regular n-gon with INRADIUS r, the area is given by

$$A = nr^2 \tan\left(\frac{\pi}{n}\right), \tag{2}$$

edge length by

$$a = 2r \tan\left(\frac{\pi}{n}\right), \tag{3}$$

and the perimeter is given by

$$p = na = 2nr \tan\left(\frac{\pi}{n}\right). \tag{4}$$

Thus,

$$Q_n = \frac{\pi}{n \tan\left(\frac{\pi}{n}\right)}, \tag{5}$$

which converges to 1 for $n \to \infty$.

See also ISOPERIMETRIC INEQUALITY

Isosceles Tetrahedron

A nonregular TETRAHEDRON in which each pair of opposite EDGES are equal such that all triangular faces are congruent. A TETRAHEDRON is isosceles IFF the sum of the face angles at each VERTEX is 180°, and IFF its INSPHERE and CIRCUMSPHERE are concentric.

The only way for all the faces of a general TETRAHEDRON to have the same PERIMETER or to have the same AREA is for them to be fully congruent, in which case the tetrahedron is isosceles. If the CIRCUMCENTER and the INCENTER of a general TETRAHEDRON coincide, then the TETRAHEDRON is isosceles (Altshiller-Court 1930, p. 97).

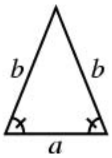
Isosceles Trapezoid



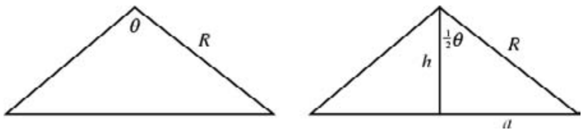
A TRAPEZOID in which the base angles are equal.

See also TRAPEZOID

References

Harris, J. W. and Stocker, H. *Handbook of Mathematics and Computational Science.* New York: Springer-Verlag, p. 83, 1998.

Isosceles Triangle

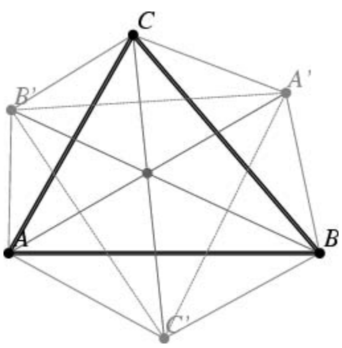


A TRIANGLE with two equal sides (and two equal ANGLES). The name derives from the Greek *iso* (same) and *skelos* (LEG). The height of the above isosceles triangle can be found from the PYTHAGOREAN THEOREM as

$$h = \sqrt{b^2 - \tfrac{1}{4}a^2}. \tag{1}$$

The AREA is therefore given by

$$A = \tfrac{1}{2}ah = \tfrac{1}{2}a\sqrt{b^2 - \tfrac{1}{4}a^2}. \qquad (2)$$



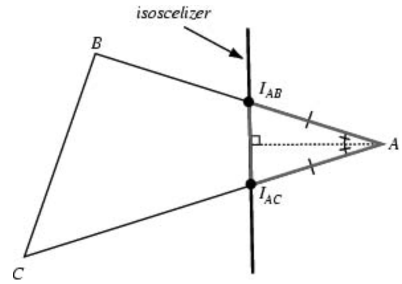
There is a surprisingly simple relationship between the AREA and VERTEX ANGLE θ. As shown in the above diagram, simple TRIGONOMETRY gives

$$h = R\cos\left(\tfrac{1}{2}\theta\right) \qquad (3)$$

$$a = R\sin\left(\tfrac{1}{2}\theta\right), \qquad (4)$$

so the AREA is

$$A = \tfrac{1}{2}(2a)h = ah = R^2\cos\left(\tfrac{1}{2}\theta\right)\sin\left(\tfrac{1}{2}\theta\right) = \tfrac{1}{2}R^2\sin\theta. \qquad (5)$$



Erecting similar isosceles triangles on the edges of an initial triangle ΔABC gives another triangle $\Delta A'B'C'$ such that AA', BB', and CC' concur. The triangles are therefore PERSPECTIVE TRIANGLES.

No set of $n > 6$ points in the PLANE can determine only ISOSCELES TRIANGLES.

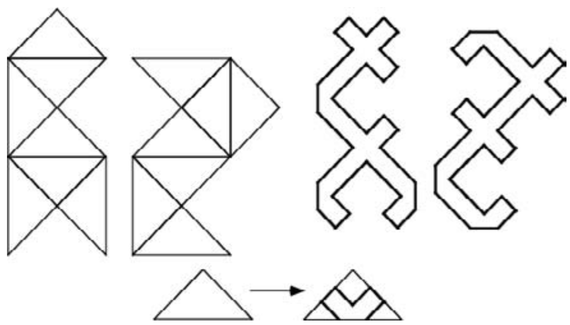
Isoscelizer

An isoscelizer of an (interior) ANGLE A in a TRIANGLE ΔABC is a LINE through points $I_{AB}I_{AC}$ where I_{AB} lies on AB and I_{AC} on AC such that $\Delta AI_{AB}I_{AC}$ is an ISOSCELES TRIANGLE. An isoscelizer is therefore a line perpendicular to an ANGLE BISECTOR, and if the angle is A, the line is known as an A-isoscelizer. There are obviously an infinite number of isoscelizers for any given angle. Isoscelizers were invented by P. Yff in 1963.

Through any point P draw the line parallel to BC as well as the corresponding ANTIPARALLEL. Then the A-isoscelizer through P bisects the angle formed by the parallel and the antiparallel. Another way of saying this is that an isoscelizer is a line which is both parallel and antiparallel to itself (P. Yff).

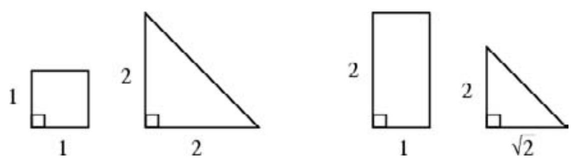
Let $\mathbf{u}_1 = (u_{1x}, u_{1y})$ and $\mathbf{u}_2 = (u_{2x}, u_{2y})$ be the unit vectors from a given vertex $\mathbf{v} = (v_x, v_y)$, let $X = (x, y)$ be a point in the interior of a triangle through which an isoscelizer passes, and the side lengths of the isosceles triangle be l. Then setting the POINT-LINE DISTANCE from the vector (u_1, u_2) to the point $\mathbf{x}$ equal to 0 gives

$$(y_2 - y_1)(x_0 - x_1) - (x_2 - x_1)(y_0 - y_1) = 0 \qquad (1)$$



$$l(u_{2y} - u_{1y})[(x - v_x) - lu_{1x}]$$

$$-l(u_{2x} - u_{1x})[(y - v_y) - lu_{1y}] = 0 \qquad (2)$$



$$l = \frac{(x - v_x)(u_{2y} - u_{1y}) - (y - v_y)(u_{2x} - u_{1x})}{u_{1x}u_{2y} - u_{2x}u_{1y}}. \qquad (3)$$

Isospectral Manifolds

DRUMS that sound the same, i.e., have the same eigenfrequency spectrum. Two drums with differing AREA, PERIMETER, or GENUS can always be distinguished. However, Kac (1966) asked if it was possible to construct differently shaped drums which have the same eigenfrequency spectrum. This question was answered in the affirmative by Gordon *et al.* (1992). Two such isospectral manifolds are shown in the right figure above (Cipra 1992).

Furthermore, pairs of separate drums (having the same total area) can be constructed which have the same eigenfrequency spectrum when played together (illustrated above). Therefore, you cannot hear the shape of a two-piece band (Zwillinger 1995, p. 426).

Isothermal Parameterization

A parameterization is isothermal if, for $\zeta \equiv u + iv$ and

$$\phi_k(\zeta) = \frac{\partial x_k}{\partial u} - i\frac{\partial x_k}{\partial v},$$

the identity

$$\phi_1^2(\zeta) + \phi_2^2(\zeta) + \phi_3^2(\zeta) = 0$$

holds.

Isotomic Conjugate Point

The point of concurrence Q of the ISOTOMIC LINES relative to a point P. The isotomic conjugate $\alpha' : \beta' : \gamma'$ of a point with TRILINEAR COORDINATES $\alpha : \beta : \gamma$ is

$$(a^2\alpha)^{-1} : (b^2\beta)^{-1} : (c^2\gamma)^{-1}. \quad (1)$$

The isotomic conjugate of a LINE d having trilinear equation

$$l\alpha + m\beta + n\gamma \quad (2)$$

is a CONIC SECTION circumscribed on the TRIANGLE ΔABC (Casey 1893, Vandeghen 1965). The isotomic conjugate of the LINE AT INFINITY having trilinear equation

$$a\alpha + b\beta + c\gamma = 0 \quad (3)$$

is STEINER'S ELLIPSE

$$\frac{\beta'\gamma'}{a} + \frac{\gamma'\alpha'}{b} + \frac{\alpha'\beta'}{c} = 0 \quad (4)$$

(Vandeghen 1965). The type of CONIC SECTION to which d is transformed is determined by whether the line d meets STEINER'S ELLIPSE E.

1. If d does not intersect E, the isotomic transform is an ELLIPSE.
2. If d is tangent to E, the transform is a PARABOLA.
3. If d cuts E, the transform is a HYPERBOLA, which is a RECTANGULAR HYPERBOLA if the line passes through the isotomic conjugate of the ORTHOCENTER

(Casey 1893, Vandeghen 1965).

There are four points which are isotomically self-conjugate: the CENTROID M and each of the points of intersection of lines through the VERTICES PARALLEL to the opposite sides. The isotomic conjugate of the EULER LINE is called JERABEK'S HYPERBOLA (Casey 1893, Vandeghen 1965).

Vandeghen (1965) calls the transformation taking points to their isotomic conjugate points the CEVIAN TRANSFORM. The product of isotomic and ISOGONAL is a COLLINEATION which transforms the sides of a TRIANGLE to themselves (Vandeghen 1965).

Isotomic Lines

Given a point P in the interior of a TRIANGLE $\Delta A_1A_2A_3$, draw the CEVIANS through P from each VERTEX which meet the opposite sides at P_1, P_2, and P_3. Now, mark off point Q_1 along side A_2A_3 such that $A_3P_1 = A_2Q_1$, etc., i.e., so that Q_i and P_i are equidistance from the MIDPOINT of A_jA_k. The lines A_1Q_1, A_2Q_2, and A_3Q_3 then coincide in a point Q known as the ISOTOMIC CONJUGATE POINT.

See also CEVIAN, ISOTOMIC CONJUGATE POINT, MIDPOINT

Isotone Map

A MAP which is monotone increasing and therefore order-preserving.

Isotope

To rearrange without cutting or pasting.

Isotopy

A HOMOTOPY from one embedding of a MANIFOLD M in N to another such that at every time, it is an embedding. The notion of isotopy is category independent, so notions of topological, piecewise-linear, smooth, isotopy (and so on) exist. When no explicit mention is made, "isotopy" usually means "smooth isotopy."

Isotropic Line

A LINE in the COMPLEX PLANE with SLOPE $\pm i$.

References

Graustein, W. C. *Introduction to Higher Geometry.* New York: Macmillan, p. 121, 1930.

Isotropic Tensor

A TENSOR which has the same components in all rotated coordinate systems. All rank-0 TENSORS (SCALARS) are isotropic, but no rank-1 TENSORS (VECTORS) are. The unique rank-2 isotropic tensor is the KRONECKER DELTA. The number of isotropic tensors of rank 0, 1, 2, ... are 1, 0, 1, 1, 3, 6, 15, 36, 91, 232, ... (Sloane's A005043). These numbers are called the Motzkin sum numbers and are given by the RECURRENCE RELATION

$$a(n) = \frac{(n-1)[2a(n-1) + 3a(n-2)]}{n+1}$$

with $a(1) = 0$ and $a(2) = 1$.

Starting at rank 5, SYZYGIES play a role in restricting the number of isotropic tensors. In particular, SYZYGIES occur at rank 5, 7, 8, and all higher ranks.

Isotropy Group

Some elements of a GROUP G ACTING on a space X may fix a point x. These group elements form a SUBGROUP called the isotropy group, defined by

$$G_x = \{g \in G \text{ such that } gx = x\}.$$

For example, consider the group $SO(3)$ of all rotations of a sphere $\mathbb{S}^2$. Let x be the north pole $(0, 0, 1)$. Then a rotation which does not change x must turn about the usual axis, leaving the north pole and the south pole fixed. These rotations correspond to the action of the circle group $\mathbb{S}^1$ on the equator.

When two points x and y are on the same ORBIT, say $y = gx$, then the isotropy groups are CONJUGATE SUBGROUPS. More precisely, $G_y = gG_xg^{-1}$. In fact, any subgroup conjugate to G_x occurs as an isotropy group G_y to some point y on the same orbit as x.

Isovolume Problem

Find the surface enclosing the maximum VOLUME per unit SURFACE AREA, $I \equiv V/S$. The solution is a SPHERE, which has

$$I_{\text{sphere}} = \frac{\frac{4}{3}\pi r^3}{4\pi r^2} = \tfrac{1}{3}r.$$

The fact that a sphere solves the isovolume problem was only proved as recently as 1882 by Schwarz (Haas 2000).

Iverson Bracket

Let S be a mathematical statement, then the Iverson bracket is defined by

$$[S] \equiv \begin{cases} 0 & \text{if } S \text{ is false} \\ 1 & \text{if } S \text{ is true.} \end{cases}$$

This notation conflicts with the brackets sometimes used to denote the FLOOR FUNCTION. (However, because of the elegant symmetry of the FLOOR FUNCTION and CEILING FUNCTION symbols $\lfloor x \rfloor$ and $\lceil x \rceil$, the use of $[x]$ to denote the FLOOR FUNCTION should be deprecated.) The Iverson bracket is implemented in *Mathematica* 4.1 as `Boole[S]`.

Jackson's Theorem

Jackson's theorem is a statement about the error $E_n(f)$ of the best uniform approximation to a REAL FUNCTION $f(x)$ on $[-1, 1]$ by REAL POLYNOMIALS of degree at most n. Let $f(x)$ be of bounded variation in $[-1, 1]$ and let M' and V' denote the least upper bound of $|f(x)|$ and the total variation of $f(x)$ in $[-1, 1]$, respectively. Given the function

$$F(x) = F(-1) + \int_{-1}^{x} f(x)dx, \tag{1}$$

then the coefficients

$$a_n = \tfrac{1}{2}(2n+1)\int_{-1}^{1} F(x)P_n(x)dx \tag{2}$$

of its LEGENDRE SERIES, where $P_n(x)$ is a LEGENDRE POLYNOMIAL, satisfy the inequalities

$$|a_n| < \begin{cases} \dfrac{6}{\sqrt{\pi}}(M'+V')n^{-3/2} & \text{for } n \geq 1 \\ \dfrac{4}{\sqrt{\pi}}(M'+V')n^{-3/2} & \text{for } n \geq 1 \end{cases} \tag{3}$$

Moreover, the LEGENDRE SERIES of $F(x)$ converges uniformly and absolutely to $F(x)$ in $[-1, 1]$.

Bernstein strengthened Jackson's theorem to

$$2nE_{2n}(\alpha) \leq \frac{4n}{\pi(2n+1)} < \frac{2}{\pi} = 0.6366. \tag{4}$$

A specific application of Jackson's theorem shows that if

$$\alpha(x) = |x|, \tag{5}$$

then

$$E_n(\alpha) \leq \frac{6}{n}. \tag{6}$$

Jacobi Differential Equation

$$(1-x^2)y''+[\beta-\alpha-(\alpha+\beta+2)x]y' +n(n+\alpha+\beta+1)y=0 \tag{1}$$

or

$$\frac{d}{dx}\left[(1-x)^{\alpha+1}(1+x)^{\beta+1}y'\right]+n(n+\alpha+\beta+1) \times(1-x)^{\alpha}(1+x)^{\beta}y=0. \tag{2}$$

The solutions are JACOBI POLYNOMIALS $P_n^{(\alpha,\beta)}(x)$ or, in terms of hypergeometric functions, as

$$y(x)=C_1\,{}_2F_1\left(-n,n+1+\alpha+\beta,1+\alpha,\tfrac{1}{2}(x-1)\right) +2^{\alpha}(x-1)^{-\alpha}C_2\,{}_2F_1\left(-n-\alpha,n+1+\beta,1-\alpha,\tfrac{1}{2}(1-x)\right). \tag{3}$$

The equation (2) can be transformed to

$$\frac{d^2y}{dx^2}+\left[\frac{1}{4}\frac{1-\alpha^2}{(1-x)^2}+\frac{1}{4}\frac{1-\beta^2}{(1+x)^2} +\frac{n(n+\alpha+\beta+1)+\frac{1}{2}(\alpha+1)(\beta+1)}{1-x^2}\right]u=0, \tag{4}$$

where

$$u(x)=(1-x)^{(\alpha+1)/2}(1+x)^{(\beta+1)/2}P_n^{(\alpha,\beta)}(x), \tag{5}$$

and

$$\frac{d^2u}{d\theta^2}+\left[\frac{\frac{1}{4}-\alpha^2}{4\sin^2\left(\frac{1}{2}\theta\right)}+\frac{\frac{1}{4}-\beta^2}{4\cos^2\left(\frac{1}{2}\theta\right)}+\left(n+\frac{\alpha+\beta+1}{2}\right)^2\right]u =0, \tag{6}$$

where

$$u(\theta)=\sin^{\alpha+1/2}\left(\tfrac{1}{2}\theta\right)\cos^{\beta+1/2}\left(\tfrac{1}{2}\theta\right)P_n^{(\alpha,\beta)}(\cos\theta). \tag{7}$$

Zwillinger (1997, p. 123) gives a related differential equation he terms Jacobi's equation

$$x(1-x)y''+[\gamma-(\alpha+1)x]y'+n(\alpha+n)y=0 \tag{8}$$

(Iyanaga and Kawada 1980, p. 1480), which has solution

$$y=C_1\,{}_2F_1(-n,n+\alpha,\gamma,x) -(-1)^{-\gamma}x^{1-\gamma}C_2\,{}_2F_1(1-n-\gamma,1+n+\alpha-\gamma,2-\gamma,x). \tag{9}$$

Zwillinger (1997, p. 120; duplicated twice) also gives another types of ordinary differential equation called a Jacobi equation,

$$(a_1+b_1x+c_1y)(xy'-y)-(a_2+b_2x+c_2y)y' +(a_3+b_3x+c_3y)=0 \tag{10}$$

(Ince 1956, p. 22).
In the CALCULUS OF VARIATIONS, the PARTIAL DIFFERENTIAL EQUATION

$$\frac{d}{dx}\Omega_{\eta'}-\Omega_{\eta}=\frac{d}{dx}\left(f_{y'y}\eta+f_{y'y}\eta'\right)-\left(f_{yy}\eta+f_{yy'}\eta'\right)=0, \tag{11}$$

where

$$\Omega(x,\eta,\eta')\equiv\tfrac{1}{2}\left(f_{yy}\eta^2+2f_{yy'}\eta\eta'+f_{y'y}\eta'^2\right) \tag{12}$$

is called the Jacobi differential equation.

Jacobi Differential Equation (Calculus of Variations)

$$u(x)=(1-x)^{(\alpha+1)/2}(1+x)^{(\beta+1)/2}P_n^{(\alpha,\beta)}(x),$$

where

$$\frac{d^2u}{d\theta^2}+\left[\frac{\frac{1}{4}-\alpha^2}{4\sin^2\left(\frac{1}{2}\theta\right)}+\frac{\frac{1}{4}-\beta^2}{4\cos^2\left(\frac{1}{2}\theta\right)}+\left(n+\frac{\alpha+\beta+1}{2}\right)^2\right]u =0,$$

This equations arises in the CALCULUS OF VARIATIONS.

Jacobi Elliptic Functions

The Jacobi elliptic functions are standard forms of ELLIPTIC FUNCTIONS. The three basic functions are

denoted $\mathrm{cn}(u,k)$, $\mathrm{dn}(u,k)$, and $\mathrm{sn}(u,k)$, where k is known as the MODULUS. The arise from the inversion of the ELLIPTIC INTEGRAL OF THE FIRST KIND,

$$u = F(\phi, k) = \int_o^{\phi} \frac{dt}{\sqrt{1 - k^2 \sin^2 t}}, \tag{1}$$

where $0 < k^2 < 1$, $k = \mathrm{mod}\ u$ is the MODULUS, and $\phi = \mathrm{am}(u,k) = \mathrm{am}(u)$ is the AMPLITUDE, giving

$$\phi = F^{-1}(u,k) = \mathrm{am}(u,k) = \mathrm{am}(u). \tag{2}$$

From this, it follows that

$$\sin\phi = \sin(\mathrm{am}(u,k)) = \sin(\mathrm{am}\ u) = \mathrm{sn}(u,k) = \mathrm{sn}(u) \tag{3}$$

$$\cos\phi = \cos(\mathrm{am}(u,k)) = \cos(\mathrm{am}\ u) = \mathrm{cn}(u,k) = \mathrm{cn}(u) \tag{4}$$

$$\sqrt{1-k^2\sin^2\phi} = \sqrt{1-k^2\sin^2(\mathrm{am}(u,k))} = \sqrt{1-k^2\,\mathrm{sn}^2\,u} = \mathrm{dn}(u,k) = \mathrm{dn}(u). \tag{5}$$

These functions are doubly periodic generalizations of the trigonometric functions satisfying

$$\mathrm{sn}(u,0) = \sin u \tag{6}$$

$$\mathrm{cn}(u,0) = \cos u \tag{7}$$

$$\mathrm{dn}(u,0) = 1. \tag{8}$$

In terms of JACOBI THETA FUNCTIONS,

$$\mathrm{sn}(u,k) = \frac{\vartheta_3}{\vartheta_4}\frac{\vartheta_1(u\vartheta_3^{-2})}{\vartheta_4(u\vartheta_3^{-2})} \tag{9}$$

$$\mathrm{cn}(u,k) = \frac{\vartheta_4}{\vartheta_2}\frac{\vartheta_2(u\vartheta_3^{-2})}{\vartheta_4(u\vartheta_3^{-2})} \tag{10}$$

$$\mathrm{dn}(u,k) = \frac{\vartheta_4}{\vartheta_3}\frac{\vartheta_3(u\vartheta_3^{-2})}{\vartheta_4(u\vartheta_3^{-2})} \tag{11}$$

(Whittaker and Watson 1990, p. 492), where $\vartheta_i \equiv \vartheta_i(0)$ (Whittaker and Watson 1990, p. 464). Ratios of Jacobi elliptic functions are denoted by combining the first letter of the NUMERATOR elliptic function with the first of the DENOMINATOR elliptic function. The multiplicative inverses of the elliptic functions are denoted by reversing the order of the two letters. These combinations give a total of 12 functions: cd, cn, cs, dc, dn, ds, nc, nd, ns, sc, sd, and sn. The AMPLITUDE ϕ is defined in terms of sn u by

$$y = \sin\phi = \mathrm{sn}(u,k). \tag{12}$$

The k argument is often suppressed for brevity so, for example, $\mathrm{sn}(u,k)$ can be written as sn u.

The Jacobi elliptic functions are periodic in $K(k)$ and $K'(k)$ as

$$\mathrm{sn}(u + 2mK + 2niK', k) = (-1)^m\,\mathrm{sn}(u,k) \tag{13}$$

$$\mathrm{cn}(u + 2mK + 2niK', k) = (-1)^{m+n}\,\mathrm{cn}(u,k) \tag{14}$$

$$\mathrm{dn}(u + 2mK + 2niK', k) = (-1)^n\,\mathrm{dn}(u,k), \tag{15}$$

where $K(k)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND, $K'(k) \equiv K(k')$, and $k' \equiv \sqrt{1-k^2}$ (Whittaker and Watson 1990, p. 503).

The cn x, dn x, and sn x functions may also be defined as solutions to the differential equations

$$\frac{d^2y}{dx^2} = -(1+k^2)y + 2k^2y^3 \tag{16}$$

$$\frac{d^2y}{dx^2} = -(1-2k^2)y - 2k^2y^3 \tag{17}$$

$$\frac{d^2y}{dx^2} = (2-k^2)y - 2y^3. \tag{18}$$

The standard Jacobi elliptic functions satisfy the identities

$$\mathrm{sn}^2\,u + \mathrm{cn}^2\,u = 1 \tag{19}$$

$$k^2\,\mathrm{sn}^2\,u + \mathrm{dn}^2\,u = 1 \tag{20}$$

$$k^2\,\mathrm{cn}^2\,u + k'^2 = \mathrm{dn}^2\,u \tag{21}$$

$$\mathrm{cn}^2\,u + k'^2\,\mathrm{sn}^2\,u = \mathrm{dn}^2\,u. \tag{22}$$

Special values include

$$\mathrm{cn}(0,k) = \mathrm{cn}(0) = 1 \tag{23}$$

$$\mathrm{cn}(K(k),k) = \mathrm{cn}(K(k)) = 0 \tag{24}$$

$$\mathrm{dn}(0,k) = \mathrm{dn}(0) = 1 \tag{25}$$

$$\mathrm{dn}(K(k),k) = \mathrm{dn}(K(k)) = k' \equiv \sqrt{1-k^2}, \tag{26}$$

$$\mathrm{sn}(0,k) = \mathrm{sn}(0) = 0 \tag{27}$$

$$\mathrm{sn}(K(k),k) = \mathrm{sn}(K(k)) = 1, \tag{28}$$

where $K = K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND and $k' = \sqrt{1-k^2}$ is the complementary MODULUS (Whittaker and Watson 1990, pp. 498–99), and

$$\mathrm{cn}(u,1) = \mathrm{sech}\ u \tag{29}$$

$$\mathrm{dn}(u,1) = \mathrm{sech}\ u \tag{30}$$

$$\mathrm{sn}(u,1) = \tanh u. \tag{31}$$

In terms of integrals,

$$u = \int_0^{\mathrm{sn}\ u} (1-t^2)^{-1/2}(1-k^2t^2)^{-1/2}\,dt \tag{32}$$

$$= \int_{\mathrm{ns}\ u}^{\infty} (t^2-1)^{-1/2}(t^2-l^2)^{-1/2}\,dt \tag{33}$$

$$= \int_{\mathrm{cn}\ u}^{1} (1-t^2)^{-1/2}(k'^2+k^2t^2)^{-1/2}\,dt \tag{34}$$

$$= \int_1^{\mathrm{nc}\ u} (t^2-1)^{-1/2}(k'^2t^2+k^2)^{-1/2}\,dt \tag{35}$$

$$= \int_{\mathrm{dn}\ u}^1 (1-t^2)^{-1/2}(t^2-k'^2)^{-1/2}\,dt \tag{36}$$

$$= \int_1^{\mathrm{nd}\ u} (t^2-1)^{-1/2}(1-k'^2t^2)^{-1/2}\,dt \tag{37}$$

$$= \int_0^{\mathrm{sc}\ u} (1+t^2)^{-1/2}(1+k'^2t^2)^{-1/2}\,dt \tag{38}$$

$$= \int_{\mathrm{cs}\ u}^\infty (t^2+1)^{-1/2}(t^2+k'^2)^{-1/2}\,dt \tag{39}$$

$$= \int_0^{\mathrm{sd}\ u} (1-k'^2t^2)^{-1/2}(1+k^2t^2)^{-1/2}\,dt \tag{40}$$

$$= \int_{\mathrm{ds}\ u}^\infty (t^2-k'^2)^{-1/2}(t^2+k^2)^{-1/2}\,dt \tag{41}$$

$$= \int_1^{\mathrm{cd}\ u} (1-t^2)^{-1/2}(1-k^2t^2)^{-1/2}\,dt \tag{42}$$

$$= \int_{\mathrm{dc}\ u}^1 (t^2-1)^{-1/2}(t^2-k^2)^{-1/2}\,dt \tag{43}$$

(Whittaker and Watson 1990, p. 494).

Jacobi elliptic functions addition formulas include

$$\mathrm{sn}(u+v) = \frac{\mathrm{sn}\ u\ \mathrm{cn}\ v\ \mathrm{dn}\ v + \mathrm{sn}\ v\ \mathrm{cn}\ u\ \mathrm{dn}\ u}{1 - k^2\ \mathrm{sn}^2\ u\ \mathrm{sn}^2\ v} \tag{44}$$

$$\mathrm{cn}(u+v) = \frac{\mathrm{cn}\ u\ \mathrm{cn}\ v - \mathrm{sn}\ u\ \mathrm{sn}\ v\ \mathrm{dn}\ u\ \mathrm{dn}\ v}{1 - k^2\ \mathrm{sn}^2\ u\ \mathrm{sn}^2\ v} \tag{45}$$

$$\mathrm{dn}(u+v) = \frac{\mathrm{dn}\ u\ \mathrm{dn}\ v - k^2\mathrm{sn}\ u\ \mathrm{sn}\ v\ \mathrm{cn}\ u\ \mathrm{cn}\ v}{1 - k^2\ \mathrm{sn}^2\ u\ \mathrm{sn}^2\ v}. \tag{46}$$

Extended to integral periods,

$$\mathrm{sn}(u+K) = \frac{\mathrm{cn}\ u}{\mathrm{dn}\ u} \tag{47}$$

$$\mathrm{cn}(u+K) = \frac{k'\ \mathrm{sn}\ u}{\mathrm{dn}\ u} \tag{48}$$

$$\mathrm{dn}(u+K) = \frac{k'}{\mathrm{dn}\ u} \tag{49}$$

$$\mathrm{sn}(u+2K) = -\mathrm{sn}\ u \tag{50}$$

$$\mathrm{cn}(u+2K) = -\mathrm{cn}\ u \tag{51}$$

$$\mathrm{dn}(u+2K) = \mathrm{dn}\ u \tag{52}$$

For COMPLEX arguments,

$$\mathrm{sn}(u+iv) = \frac{\mathrm{sn}(u,k)\ \mathrm{dn}(v,k')}{1-\mathrm{dn}^2(u,k)\ \mathrm{sn}^2(v,k')} + \frac{i\ \mathrm{cn}(u,k)\ \mathrm{dn}(u,k)\ \mathrm{sn}(v,k')\ \mathrm{cn}(v,k')}{1-\mathrm{dn}^2(u,k)\ \mathrm{sn}^2(v,k')} \tag{53}$$

$$\mathrm{cn}(u+iv) = \frac{\mathrm{cn}(u,k)\ \mathrm{cn}(v,k')}{1-\mathrm{dn}^2(u,k)\ \mathrm{sn}^2(v,k')} + \frac{i\ \mathrm{sn}(u,k)\ \mathrm{dn}(u,k)\ \mathrm{sn}(v,k')\ \mathrm{dn}(v,k')}{1-\mathrm{dn}^2(u,k)\ \mathrm{sn}^2(v,k')} \tag{54}$$

$$\mathrm{dn}(u+iv) = \frac{\mathrm{dn}(u,k)\ \mathrm{cn}(v,k')\ \mathrm{dn}(v,k')}{1-\mathrm{dn}^2(u,k)\ \mathrm{sn}^2(v,k')} + \frac{ik^2\ \mathrm{sn}(u,k)\ \mathrm{cn}(u,k)\ \mathrm{sn}(v,k')}{1-\mathrm{dn}^2(u,k)\ \mathrm{sn}^2(v,k')} \tag{55}$$

DERIVATIVES of the Jacobi elliptic functions include

$$\frac{d\ \mathrm{sn}\ u}{du} = \mathrm{cn}\ u\ \mathrm{dn}\ u \tag{56}$$

$$\frac{d\ \mathrm{cn}\ u}{du} = -\mathrm{sn}\ u\ \mathrm{dn}\ u \tag{57}$$

$$\frac{d\ \mathrm{dn}\ u}{du} = -k^2\ \mathrm{sn}\ u\ \mathrm{cn}\ u \tag{58}$$

(Hille 1969, p. 66; Zwillinger 1997, p. 136).

Double-period formulas involving the Jacobi elliptic functions include

$$\mathrm{sn}(2u) = \frac{2\ \mathrm{sn}\ u\ \mathrm{cn}\ u\ \mathrm{dn}\ u}{1 - k^2\ \mathrm{sn}^4\ u} \tag{59}$$

$$\mathrm{cn}(2u) = \frac{1 - 2\ \mathrm{sn}^2\ u + k^2\ \mathrm{sn}^4\ u}{1 - k^2\ \mathrm{sn}^4\ u} \tag{60}$$

$$\mathrm{dn}(2u) = \frac{1 - 2k^2\ \mathrm{sn}^2\ u + k^2\ \mathrm{sn}^4\ u}{1 - k^2\ \mathrm{sn}^4\ u}. \tag{61}$$

Half-period formulas involving the Jacobi elliptic functions include

$$\mathrm{sn}\left(\tfrac{1}{2}K\right) = \frac{1}{\sqrt{1+k'}} \tag{62}$$

$$\mathrm{cn}\left(\tfrac{1}{2}K\right) = \sqrt{\frac{k'}{1+k'}} \tag{63}$$

$$\mathrm{dn}\left(\tfrac{1}{2}K\right) = \sqrt{k'}. \tag{64}$$

Squared formulas include

$$\mathrm{sn}^2\ u = \frac{1 - \mathrm{cn}(2u)}{1 + \mathrm{dn}(2u)} \tag{65}$$

$$\mathrm{cn}^2\ u = \frac{\mathrm{dn}(2u) + \mathrm{cn}(2u)}{1 + \mathrm{dn}(2u)} \tag{66}$$

$$\mathrm{dn}^2 u = \frac{\mathrm{dn}(2u)+\mathrm{cn}(2u)}{1+\mathrm{cn}(2u)}. \tag{67}$$

Jacobi Function of the First Kind

JACOBI POLYNOMIAL

Jacobi Function of the Second Kind

$$Q_n^{(\alpha,\beta)}(x) = 2^{-n-1}(x-1)^{-\alpha}(x+1)^{-\beta} \times \int_{-1}^{1}(1-t)^{n+\alpha}(1+t)^{n+\beta}(x-t)^{-n-1}\,dt.$$

In the exceptional case $n=0$, $\alpha+\beta+1=0$, a nonconstant solution is given by

$$Q^{(\alpha)}(x) = \ln(x+1) + \pi^{-1}\sin(\pi\alpha)(x-1)^{-\alpha}(x+1)^{-\beta} \times \int_{-1}^{1}\frac{(1-t)^{\alpha}(1+t)^{\beta}}{x-t}\ln(1+t)\,dt.$$

Jacobi Identities

"The" Jacobi identity is a relationship

$$[A,[B,C]]+[B,[C,A]]+[C,[A,B]]=0, \tag{1}$$

between three elements A, B, and C, where $[A, B]$ is the COMMUTATOR. The elements of a LIE ALGEBRA satisfy this identity.

Relationships between the Q-FUNCTIONS Q_i are also known as Jacobi identities:

$$Q_1Q_2Q_3 = 1, \tag{2}$$

equivalent to the JACOBI TRIPLE PRODUCT (Borwein and Borwein 1987, p. 65) and

$$Q_2^8 = 16qQ_1^8 + Q_3^8, \tag{3}$$

where

$$q \equiv e^{-\pi K'(k)/K(k)}, \tag{4}$$

$K=K(k)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND, and $K'(k)=K(k')=K\left(\sqrt{1-k^2}\right)$. Using WEBER FUNCTIONS

$$f_1 = q^{-1/24}Q_3 \tag{5}$$

$$f_2 = 2^{1/2}q^{1/12}Q_1 \tag{6}$$

$$f = q^{-1/24}Q_2, \tag{7}$$

(5) and (6) become

$$f_1f_2f = \sqrt{2} \tag{8}$$

$$f^8 = f_1^8 + f_2^8 \tag{9}$$

(Borwein and Borwein 1987, p. 69).

Jacobi Matrix

JACOBI ROTATION MATRIX, JACOBIAN

Jacobi Method

A method of diagonalizing a MATRIX A using JACOBI ROTATION MATRICES P_{pq}. It consists of a sequence of ORTHOGONAL SIMILARITY TRANSFORMATIONS OF THE FORM

$$\mathsf{A}' = \mathsf{P}_{pq}^T \mathsf{A} \mathsf{P}_{pq},$$

each of which eliminates one off-diagonal element. Each application of P_{pq} affects only rows and columns of A, and the sequence of such matrices is chosen so as to eliminate the off-diagonal elements.

See also JACOBI ALGORITHM, JACOBI ROTATION MATRIX

Jacobi Polynomial

Also known as the HYPERGEOMETRIC POLYNOMIALS, they occur in the study of ROTATION GROUPS and in the solution to the equations of motion of the symmetric top. They are solutions to the JACOBI DIFFERENTIAL EQUATION. Plugging

$$y = \sum_{\nu=0}^{\infty} a_\nu (x-1)^\nu \quad (1)$$

into the differential equation gives the RECURRENCE RELATION

$$[\gamma - \nu(\nu+\alpha+\beta+1)]a_\nu - 2(\nu+1)(\nu+\alpha+1)a_{\nu+1} = 0 \quad (2)$$

for $\nu = 0, 1, \ldots$, where

$$\gamma \equiv n(n+\alpha+\beta+1). \quad (3)$$

Solving the RECURRENCE RELATION gives

$$P_n^{(\alpha+\beta)}(x) = \frac{(-1)^n}{2^n n!}(1-x)^{-\alpha}(1+x)^{-\beta}\frac{d^n}{dx^n} \times \left[(1-x)^{\alpha+n}(1+x)^{\beta+n}\right] \quad (4)$$

for $\alpha, \beta > -1$. They form a complete orthogonal system in the interval $[-1, 1]$ with respect to the weighting function

$$w_n(x) = (1-x)^\alpha (1+x)^\beta, \quad (5)$$

and are normalized according to

$$P_n^{(\alpha,\beta)}(1) = \binom{n+\alpha}{n}, \quad (6)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. Jacobi polynomials can also be written

$$P_n^{\alpha,\beta} = \frac{\Gamma(2n+\alpha+\beta+1)}{n!\,\Gamma(n+\alpha+\beta+1)} G_n\left(\alpha+\beta+1, \beta+1, \tfrac{1}{2}(x+1)\right), \quad (7)$$

where $\Gamma(z)$ is the GAMMA FUNCTION and

$$G_n(p,q,x) \equiv \frac{n!\,\Gamma(n+p)}{\Gamma(2n+p)} P_n^{(p-q,q-1)}(2x-1). \quad (8)$$

Jacobi polynomials are ORTHOGONAL satisfying

$$\int_{-1}^{1} P_m^{(\alpha,\beta)} P_n^{(\alpha,\beta)} (1-x)^\alpha (1+x)^\beta \, dx = \frac{2^{\alpha+\beta+1}}{2n+\alpha+\beta+1} \frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}{n!\,\Gamma(n+\alpha+\beta+1)} \delta_{mn}. \quad (9)$$

The COEFFICIENT of the term x^n in $P_n^{(\alpha,\beta)}(x)$ is given by

$$A_n = \frac{\Gamma(2n+\alpha+\beta+1)}{2^n n!\,\Gamma(n+\alpha+\beta+1)}. \quad (10)$$

They satisfy the RECURRENCE RELATION

$$\begin{aligned} &2(n+1)(n+\alpha+\beta+1)(2n+\alpha+\beta)P_{n+1}^{(\alpha,\beta)}(x) \\ &= \left[(2n+\alpha+\beta+1)(\alpha^2-\beta^2) + (2n+\alpha+\beta)_3 x\right] P_n^{(\alpha,\beta)}(x) \\ &\quad -2(n+\alpha)(n+\beta)(2n+\alpha+\beta+2)P_{n-1}^{(\alpha,\beta)}(x), \end{aligned} \quad (11)$$

where $(m)_n$ is the RISING FACTORIAL

$$(m)_n \equiv m(m+1)\cdots(m+n-1) = \frac{(m+n-1)!}{(m-1)!}. \quad (12)$$

The DERIVATIVE is given by

$$\frac{d}{dx}\left[P_n^{(\alpha,\beta)}(x)\right] = \tfrac{1}{2}(n+\alpha+\beta+1)P_{n-1}^{(\alpha+1,\beta+1)}(x). \quad (13)$$

The ORTHOGONAL POLYNOMIALS with WEIGHTING FUNCTION $(b-x)^\alpha (x-a)^\beta$ on the CLOSED INTERVAL $[a, b]$ can be expressed in the form

$$[\text{const.}]P_n^{(\alpha,\beta)}\left(2\frac{x-a}{b-a} - 1\right) \quad (14)$$

(Szego 1975, p. 58).

Special cases with $\alpha = \beta$ are

$$P_{2\nu}^{(\alpha,\alpha)}(x) = \frac{\Gamma(2\nu+\alpha+1)\Gamma(\nu+1)}{\Gamma(\nu+\alpha+1)\Gamma(2\nu+1)} P_\nu^{(\alpha,-1/2)}(2x^2-1) \quad (15)$$

$$= (-1)^\nu \frac{\Gamma(2\nu+\alpha+1)\Gamma(\nu+1)}{\Gamma(\nu+\alpha+1)\Gamma(2\nu+1)} P_\nu^{(-1/2,\alpha)}(1-2x^2) \quad (16)$$

$$P_{2\nu+1}^{(\alpha,\alpha)}(x)=\frac{\Gamma(2\nu+\alpha+2)\Gamma(\nu+1)}{\Gamma(\nu+\alpha+1)\Gamma(2\nu+2)}xP_{\nu}^{(\alpha,1/2)}(2x^2-1) \quad (17)$$

$$=(-1)^{\nu}\frac{\Gamma(2\nu+\alpha+2)\Gamma(\nu+1)}{\Gamma(\nu+\alpha+1)\Gamma(2\nu+2)}xP_{\nu}^{(1/2,\alpha)}(1-2x^2). \quad (18)$$

Further identities are

$$P_n^{(\alpha+1,\beta)}(x)=\frac{2}{2n+\alpha+\beta+2}\times\frac{(n+\alpha+1)P_n^{(\alpha,\beta)}-(n+1)P_{n+1}^{(\alpha,\beta)}(x)}{1-x} \quad (19)$$

$$P_n^{(\alpha+\beta+1)}(x)=\frac{2}{2n+\alpha+\beta+2}\times\frac{(n+\beta+1)P_n^{(\alpha,\beta)}(x)+(n+1)P_{n+1}^{(\alpha,\beta)}(x)}{1+x} \quad (20)$$

$$\sum_{\nu=0}^{n}\frac{2\nu+\alpha+\beta+1}{2^{\alpha+\beta+1}}\times\frac{\Gamma(\nu+1)\Gamma(\nu+\alpha+\beta+1)}{\Gamma(\nu+\alpha+1)\Gamma(\nu+\beta+1)}P_\nu^{(\alpha,\beta)}(x)Q_\nu^{(\alpha,\beta)}(y)$$
$$=\frac{1}{2}\frac{(y-1)^{\sim\alpha}(y+1)^{\sim\beta}}{y-x}+\frac{2^{\sim\alpha\sim\beta}}{2n+\alpha+\beta+2}\times\frac{\Gamma(n+2)\Gamma(n+\alpha+\beta+2)}{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}\times\frac{P_{n+1}^{(\alpha,\beta)}(x)Q_n^{(\alpha,\beta)}(y)-P_n^{(\alpha,\beta)}(x)Q_{n+1}^{\alpha,\beta}(y)}{x-y} \quad (21)$$

(Szego 1975, p. 79).

The KERNEL POLYNOMIAL is

$$K_n^{(\alpha,\beta)}(x,y)=\frac{2^{\sim\alpha\sim\beta}}{2n+\alpha+\beta+2}\times\frac{\Gamma(n+2)\Gamma(n+\alpha+\beta+2)}{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}\times\frac{P_{n+1}^{(\alpha,\beta)}(x)P_n^{(\alpha,\beta)}(y)-P_n^{(\alpha,\beta)}(x)P_{n+1}^{(\alpha,\beta)}(y)}{x-y} \quad (22)$$

(Szego 1975, p. 71).

The DISCRIMINANT is

$$D_n^{(\alpha,\beta)}=2^{-n(n-1)}\prod_{\nu=1}^{n}\nu^{\nu-2n+2}(\nu+\alpha)^{\nu-1}(\nu+\beta)^{\nu-1}\times(n+\nu+a+\beta)^{n-\nu} \quad (23)$$

(Szego 1975, p. 143).

For $\alpha=\beta=0$, $P_n^{(0,0)}(x)$ reduces to a LEGENDRE POLYNOMIAL. The GEGENBAUER POLYNOMIAL

$$G_n(p,q,x)=\frac{n!\Gamma(n+p)}{\Gamma(2n+p)}P_n^{(p-q,q-1)}(2x-1) \quad (24)$$

and CHEBYSHEV POLYNOMIAL OF THE FIRST KIND can also be viewed as special cases of the Jacobi polynomials. In terms of the HYPERGEOMETRIC FUNCTION,

$$P_n^{(\alpha,\beta)}(x)=\binom{n+\alpha}{n}{}_2F_1(-n,n+\alpha+\beta;\ \alpha+1;\ \tfrac{1}{2}(1-x)) \quad (25)$$

$$=\frac{(\alpha+1)_n}{n!}{}_2F_1\left(-n,n+\alpha+\beta;\alpha+1;\tfrac{1}{2}(1-x)\right) \quad (26)$$

$$=\binom{n+\alpha}{n}\left(\frac{x+1}{2}\right)^2\times{}_2F_1\left(-n,-n-\beta;\alpha+1;\frac{x-1}{x+1}\right), \quad (27)$$

where $(\alpha)_n$ is the POCHHAMMER SYMBOL (Koekoek 1998).

Let N_1 be the number of zeros in $x\in(-1,1)$, N_2 the number of zeros in $x\in(-\infty,-1)$, and N_3 the number of zeros in $x\in(1,\infty)$. Define Klein's symbol

$$E(u)=\begin{cases}0 & \text{if } u\leq 0\\ \lfloor u\rfloor & \text{if } u \text{ positive and nonintegral}\\ u-1 & \text{if } u=1,2\ldots,\end{cases} \quad (28)$$

where $\lfloor x\rfloor$ is the FLOOR FUNCTION, and

$$X(\alpha,\beta)=E\left[\tfrac{1}{2}(|2n+\alpha+\beta+1|-|\alpha|-|\beta|+1)\right] \quad (29)$$

$$Y(\alpha,\beta)=E\left[\tfrac{1}{2}(-|2n+\alpha+\beta+1|+|\alpha|-|\beta|+1)\right] \quad (30)$$

$$Z(\alpha,\beta)=E\left[\tfrac{1}{2}(-|2n+\alpha+\beta+1|-|\alpha|+|\beta|+1)\right]. \quad (31)$$

If the cases $\alpha=-1, -2, ..., -n$, $\beta=-1, -2, ..., -n$, and $n+\alpha+\beta=-1, -2, ..., -n$ are excluded, then the number of zeros of $P_n^{(\alpha,\beta)}$ in the respective intervals are

$$N_1(\alpha,\beta)=\begin{cases}2\left\lfloor\tfrac{1}{2}(X+1)\right\rfloor & \text{for } (-1)^n\binom{n+\alpha}{n}\binom{n+\beta}{n}>0\\ 2\left\lfloor\tfrac{1}{2}X\right\rfloor+1 & \text{for } (-1)^n\binom{n+\alpha}{n}\binom{n+\beta}{n}<0\end{cases} \quad (32)$$

$$N_2(\alpha,\beta)=\begin{cases}2\left\lfloor\tfrac{1}{2}(Y+1)\right\rfloor & \text{for } \binom{2n+\alpha+\beta}{n}\binom{n+\beta}{n}>0\\ 2\left\lfloor\tfrac{1}{2}Y\right\rfloor+1 & \text{for } \binom{2n+\alpha+\beta}{n}\binom{n+\beta}{n}<0\end{cases} \quad (33)$$

$N_3(\alpha,\beta)$

$$= \begin{cases} 2\left\lfloor \frac{1}{2}(Z+1) \right\rfloor & \text{for } \binom{2n+\alpha+\beta}{n}\binom{n+\alpha}{n} > 0 \\ 2\left\lfloor \frac{1}{2}Z \right\rfloor + 1 & \text{for } \binom{2n+\alpha+\beta}{n}\binom{n+\alpha}{n} < 0 \end{cases} \quad (34)$$

(Szego 1975, pp. 144–46).

The first few POLYNOMIALS are

$$P_0^{(\alpha,\beta)}(x) = 1 \quad (35)$$

$$P_1^{(\alpha,\beta)}(x) = \tfrac{1}{2}[2(\alpha+1) + (\alpha+\beta+2)(x-1)] \quad (36)$$

$$P_2^{(\alpha,\beta)}(x) = \tfrac{1}{8}[4(\alpha+1)^{(2)} + 4(\alpha+\beta+3)(\alpha+2)(x-1) + (\alpha+\beta+3)(2)(x-1)^2], \quad (37)$$

where $(m)_n$ is a RISING FACTORIAL (Abramowitz and Stegun 1972, p. 793).

See Abramowitz and Stegun (1972, pp. 782–93) and Szego (1975, Ch. 4) for additional identities.

Jacobi Quadrature

JACOBI-GAUSS QUADRATURE

Jacobi Rotation Matrix

A MATRIX used in the JACOBI TRANSFORMATION method of diagonalizing MATRICES. The Jacobi rotation matrix P_{pq} contains 1s along the DIAGONAL, except for the two elements $\cos\phi$ in rows and columns p and q. In addition, all off-diagonal elements are zero except the elements $\sin\phi$ and $-\sin\phi$. The rotation angle ϕ for an initial matrix A is chosen such that

$$\cot(2\phi) = \frac{a_{qq} - a_{pp}}{2a_{pq}}.$$

Then the corresponding Jacobi rotation matrix which annihilates the off-diagonal element a_{pq} is

$$\mathsf{P}_{pq} \equiv \begin{bmatrix} 1 & & & & & & 0 \\ & \ddots & & \vdots & & ⋰ & \\ & & \cos\phi & \cdots & 0 & \cdots & \sin\phi \\ & \cdots & 0 & \cdots & 1 & \cdots & 0 & \cdots \\ & & -\sin\phi & \cdots & 0 & \cdots & \cos\phi \\ & ⋰ & & \vdots & & \ddots & \\ 0 & & & & & & 1 \end{bmatrix}$$

Jacobi Symbol

The product of LEGENDRE SYMBOLS (n/p_i) for each of the PRIME FACTORS p_i such that $m = \prod_i p_i$, denoted (n/m) or $\left(\frac{n}{m}\right)$. When m is a PRIME, the Jacobi symbol reduces to the LEGENDRE SYMBOL. (The Legendre symbol is equal to ± 1 depending on whether m is a QUADRATIC RESIDUE modulo m.) Analogously to the Legendre symbol, the Jacobi symbol is commonly generalized to have value

$$\left(\frac{n}{m}\right) = 0 \text{ if } m|n, \quad (1)$$

giving

$$\left(\frac{n}{n}\right) = 0 \quad (2)$$

as a special case. Note that the Jacobi symbol is *not defined* for $m \le 0$ or m EVEN. The Jacobi symbol is implemented in *Mathematica* as `JacobiSymbol[n, m]`.

Use of the Jacobi symbol provides the generalization of the QUADRATIC RECIPROCITY THEOREM

$$\left(\frac{m}{n}\right)\left(\frac{n}{m}\right) = (-1)^{(m-1)(n-1)/4} \quad (3)$$

for m and n RELATIVELY PRIME ODD INTEGERS with $n \ge 3$ (Nagell 1951, pp. 147–48). Written another way,

$$\left(\frac{m}{n}\right) = (-1)^{(m-1)(n-1)/4}\left(\frac{n}{m}\right) \quad (4)$$

or

$$\left(\frac{n}{m}\right) = \begin{cases} \left(\frac{m}{n}\right) & \text{for } m \text{ or } n \equiv 1 \pmod 4 \\ -\left(\frac{m}{n}\right) & \text{for } m, n \equiv 3 \pmod 4 \end{cases}. \quad (5)$$

The Jacobi symbol satisfies the same rules as the LEGENDRE SYMBOL

$$\left(\frac{n}{m}\right)\left(\frac{n}{m'}\right) = \left(\frac{n}{(mm')}\right) \quad (6)$$

$$\left(\frac{n}{m}\right)\left(\frac{n'}{m}\right) = \left(\frac{(nn')}{m}\right) \quad (7)$$

$$\left(\frac{n^2}{m}\right) = \left(\frac{n}{m^2}\right) = 1 \quad \text{if } (m,n) = 1 \quad (8)$$

$$\left(\frac{n}{m}\right) = \left(\frac{n'}{m}\right) \quad \text{if } n \equiv n' \pmod m \quad (9)$$

$$\left(\frac{-1}{m}\right) = (-1)^{(m-1)/2} = \begin{cases} 1 & \text{for } m \equiv 1 \pmod 4 \\ -1 & \text{for } m \equiv -1 \pmod 4 \end{cases} \quad (10)$$

$$\left(\frac{2}{m}\right) = (-1)^{(m^2-1)/8} = \begin{cases} 1 & \text{for } m \equiv \pm 1 \pmod 8 \\ -1 & \text{for } m \equiv \pm 3 \pmod 8 \end{cases} \quad (11)$$

Bach and Shallit (1996) show how to compute the Jacobi symbol in terms of the SIMPLE CONTINUED FRACTION of a RATIONAL NUMBER n/m.

Jacobi Theta Function

THETA FUNCTIONS

Jacobi Theta Functions

The Jacobi theta functions are the elliptic analogs of the EXPONENTIAL FUNCTION, and may be used to express the JACOBI ELLIPTIC FUNCTIONS. The theta functions are quasi-doubly periodic, and are most commonly denoted $\vartheta_n(z,q)$ in modern texts, although the notations $\Theta_n(z,q)$ and $\theta_n(z,q)$ (Borwein and Borwein 1987) are sometimes also used. Whittaker and Watson (1990, p. 487) gives a table summarizing notations used by various earlier writers. The theta functions are given in *Mathematica* by `EllipticTheta[n, z, q]`.

The theta functions may be expressed in terms of the NOME q, denoted $\vartheta_n(z,q)$, or the HALF-PERIOD RATIO τ, denoted $\vartheta_n(z|\tau)$, where $|q| < 1$ and q and τ are related by

$$q \equiv e^{i\pi\tau}. \quad (1)$$

Let the many-valued function q^{λ} be interpreted to stand for $e^{\lambda\pi i\tau}$. Then for a complex number z, the Jacobi theta functions are defined as

$$\vartheta_1(z,q) \equiv \sum_{n=-\infty}^{\infty} (-1)^{n-1/2} q^{(n+1/2)^2} e^{(2n+1)iz} \quad (2)$$

$$\vartheta_2(z,q) \equiv \sum_{n=-\infty}^{\infty} q^{(n+1/2)^2} e^{(2n+1)iz} \quad (3)$$

$$\vartheta_3(z,q) \equiv \sum_{n=-\infty}^{\infty} q^{n^2} e^{2niz} \quad (4)$$

$$\vartheta_4(z,q) \equiv \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} e^{2niz}. \quad (5)$$

Writing the doubly infinite sums as singly infinite sums gives the slightly less symmetrical forms

$$\vartheta_1(z,q) = 2\sum_{n=0}^{\infty} (-1)^n q^{(n+1/2)^2} \sin[(2n+1)z] \quad (6)$$

$$= 2q^{1/4}\sum_{n=0}^{\infty} (-1)^n q^{n(n+1)} \sin[(2n+1)z] \quad (7)$$

$$\vartheta_2(z,q) = 2\sum_{n=0}^{\infty} q^{(n+1/2)^2} \cos[(2n+1)z] \quad (8)$$

$$= 2q^{1/4}\sum_{n=0}^{\infty} q^{n(n+1)} \cos[(2n+1)z] \quad (9)$$

$$\vartheta_3(z,q) = 1 + 2\sum_{n=0}^{\infty} q^{n^2} \cos(2nz) \quad (10)$$

$$\vartheta_4(z,q) = 1 + 2\sum_{n=0}^{\infty}(-1)^n q^{n^2}\cos(2nz) \tag{11}$$

(Whittaker and Watson 1990, p. 463–64). Explicitly writing out the series gives

$$\vartheta_1(z,q) = 2q^{1/4}\sin z - 2q^{9/4}\sin(3z) + 2q^{25/4}\sin(5z) + \ldots \tag{12}$$

$$\vartheta_2(z,q) = 2q^{1/4}\cos z + 2q^{9/4}\cos(3z) + 2q^{25/4}\cos(5z) + \ldots \tag{13}$$

$$\vartheta_3(z,q) = 1 + 2q\cos(2z) + 2q^4\cos(4z) + 2q^9\cos(6z) + \ldots \tag{14}$$

$$\vartheta_4(z,q) = 1 - 2q\cos(2z) + 2q^4\cos(4z) - 2q^9\cos(6z) + \ldots \tag{15}$$

(Borwein and Borwein 1987, p. 52; Whittaker and Watson 1990, p. 464). $\vartheta_1(z,q)$ is an ODD FUNCTION of z, while the other three are even functions of z.

The following table illustrates the quasi-double periodicity of the Jacobi theta functions.

ϑ_i	$\vartheta_i(z+\pi)/\vartheta_i(z)$	$\vartheta_i(z+\tau\pi)/\vartheta_i(z)$
ϑ_1	-1	$-N$
ϑ_2	-1	N
ϑ_3	1	N
ϑ_4	1	$-N$

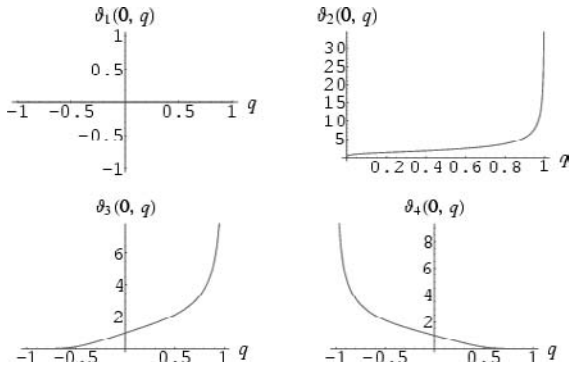
Here,

$$N \equiv q^{-1}e^{-2iz}. \tag{16}$$

The quasi-periodicity can be established as follows for the specific case of ϑ_4,

$$\vartheta_4(z+\pi,q) = \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} e^{2niz} e^{2ni\pi}$$
$$= \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} e^{2niz} = \vartheta_4(z,q) \tag{17}$$

$$\vartheta_4(z+\pi\tau,q) = \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} e^{2ni\pi t} e^{2niz}$$
$$= \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} q^{2n} e^{2niz}$$
$$= -q^{-1}e^{-2iz}\sum_{n=-\infty}^{\infty}(-1)^{n+1} q^{(n+1)^2} q^{2(n+1)iz}$$
$$= -q^{-1}e^{-2iz}\sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} q^{2niz}$$
$$= -q^{-1}e^{-2iz}\vartheta_4(z,q). \tag{18}$$



The Jacobi theta functions can be written in terms of each other:

$$\vartheta_1(z,q) = -ie^{iz+\pi i\tau/4}\vartheta_4\left(z+\tfrac{1}{4}\pi\tau, q\right) \tag{19}$$

$$\vartheta_2(z,q) = \vartheta_1\left(z+\tfrac{1}{2}\pi, q\right) \tag{20}$$

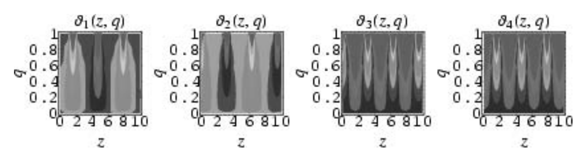
$$\vartheta_3(z,q) = \vartheta_4\left(z+\tfrac{1}{2}\pi, q\right) \tag{21}$$

Any Jacobi theta function of given arguments can be expressed in terms of any other two Jacobi theta functions with the same arguments.

Define

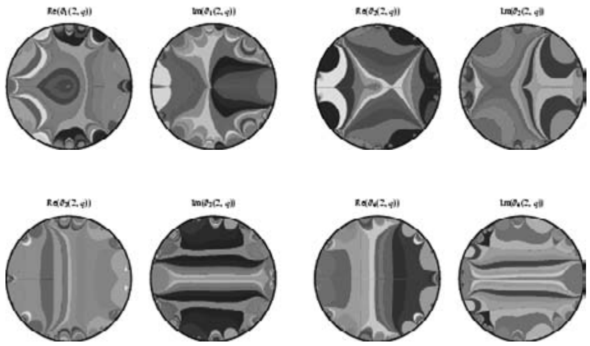
$$\vartheta_i(q) \equiv \vartheta_i(z=0,q) \tag{22}$$

to be the Jacobi theta functions with argument $z=0$, plotted above. Then the doubly infinite sums (2) to (5) take on the particularly simple forms



$$\vartheta_1(q) = 0 \tag{23}$$

$$\vartheta_2(q) = \sum_{n=-\infty}^{\infty} q^{(n+1/2)^2} \tag{24}$$



$$\vartheta_3(q) = \sum_{n=-\infty}^{\infty} q^{n^2} \tag{25}$$

$$\vartheta_4(q) = \sum_{n=-\infty}^{\infty}(-1)^n q^{n^2} \tag{26}$$

(Borwein and Borwein 1987, p. 33).

The plots above show the Jacobi theta functions plotted as a function of argument z and NOME q restricted to real values.

Particularly beautiful plots are obtained by examining the REAL and IMAGINARY PARTS of $\vartheta_i(z,q)$ for fixed z in the complex plane for $|q|<1$, illustrated above.

The Jacobi theta functions satisfy an almost bewilderingly large number of identities involving the four functions, their derivatives, multiples of their arguments, and sums of their arguments. Among the unusual identities given by Whittaker and Watson (1990) are

$$\vartheta_3(z,q)=\vartheta_3(2z,q^4)+\vartheta_2(2z,q^4) \tag{27}$$

$$\vartheta_3(z,q)=\vartheta_3(2z,q^4)-\vartheta_2(2z,q^4) \tag{28}$$

(Whittaker and Watson 1990, p. 464) and

$$\frac{\vartheta_k'(z+\pi)}{\vartheta_k(z+\pi)}=\frac{\vartheta_k'(z)}{\vartheta_k(z)} \tag{29}$$

$$\frac{\vartheta_k'(z+\pi\gamma)}{\vartheta_k(z+\pi\gamma)}=-2i+\frac{\vartheta_k'(z)}{\vartheta_k(z)} \tag{30}$$

(Whittaker and Watson 1990, p. 465), for $k=1, ..., 4$, where $\vartheta_k(z)\equiv\vartheta_k(z,q)$ and $\vartheta_i\equiv\vartheta_i(0,q)$. A class of identities involving the squares of Jacobi theta functions are

$$\vartheta_1^2(z)\vartheta_4^2=\vartheta_3^2(z)\vartheta_2^2-\vartheta_2^2(z)\vartheta_3^2 \tag{31}$$

$$\vartheta_2^2(z)\vartheta_4^2=\vartheta_4^2(z)\vartheta_2^2-\vartheta_1^2(z)\vartheta_3^2 \tag{32}$$

$$\vartheta_3^2(z)\vartheta_4^2=\vartheta_4^2(z)\vartheta_3^2-\vartheta_1^2(z)\vartheta_2^2 \tag{33}$$

$$\vartheta_4^2(z)\vartheta_4^2=\vartheta_3^2(z)\vartheta_3^2-\vartheta_2^2(z)\vartheta_2^2 \tag{34}$$

(Whittaker and Watson 1990, p. 466). Taking $z=0$ in (34) gives the special case

$$\vartheta_4^4=\vartheta_3^4-\vartheta_2^4, \tag{35}$$

which is the only identity of this type.

In addition,

$$\vartheta_3(x)=\sum_{n=-\infty}^{\infty}x^{n^2}=1+2x+2x^4+2x^9+\ldots \tag{36}$$

$$\vartheta_3^2(x)=1+4\left(\frac{x}{1-x}-\frac{x^3}{1-x^3}+\frac{x^5}{1-x^5}-\frac{x^7}{1-x^7}+\ldots\right) \tag{37}$$

$$\vartheta_3^4(x)=1+8\left(\frac{x}{1-x}+\frac{2x^2}{1-x^2}+\frac{3x^3}{1-x^3}+\frac{4x^4}{1-x^4}+\ldots\right) \tag{38}$$

The Jacobi theta functions obey addition rules such as

$$\begin{aligned}\vartheta_1(y+z)\vartheta_1(y-z)\vartheta_4^2&=\vartheta_3^2(y)\vartheta_2^2(z)-\vartheta_2^2(y)\vartheta_3^2(z)\\&=\vartheta_1^2(y)\vartheta_4^2(z)-\vartheta_4^2(y)\vartheta_1^2(z)\end{aligned} \tag{39}$$

$$\begin{aligned}\vartheta_2(y+z)\vartheta_2(y-z)\vartheta_4^2&=\vartheta_4^2(y)\vartheta_2^2(z)-\vartheta_1^2(y)\vartheta_3^2(z)\\&=\vartheta_2^2(y)\vartheta_4^2(y)-\vartheta_3^2(y)\vartheta_1^2(z)\end{aligned} \tag{40}$$

$$\begin{aligned}\vartheta_3(y+z)\vartheta_3(y-z)\vartheta_4^2&=\vartheta_4^2(y)\vartheta_3^2(z)-\vartheta_1^2(y)\vartheta_2^2(z)\\&=\vartheta_3^2(y)\vartheta_4^2(z)-\vartheta_2^2(y)\vartheta_1^2(z)\end{aligned} \tag{41}$$

$$\begin{aligned}\vartheta_4(y+z)\vartheta_4(y-z)\vartheta_4^2&=\vartheta_3^2(y)\vartheta_3^2(z)-\vartheta_2^2(y)\vartheta_2^2(z)\\&=\vartheta_4^2(y)\vartheta_4^2(z)-\vartheta_1^2(y)\vartheta_1^2(z)\end{aligned} \tag{42}$$

(Whittaker and Watson 1990, p. 487), and

$$\begin{aligned}\vartheta_3(y+z)\vartheta_3(y-z)\vartheta_2^2&=\vartheta_3^2(y)\vartheta_2^2(z)+\vartheta_4^2(y)\vartheta_1^2(z)\\&=\vartheta_2^2(y)\vartheta_3^2(z)+\vartheta_1^2(y)\vartheta_4^2(z)\end{aligned}$$

$$\begin{aligned}\vartheta_3(y+z)\vartheta_3(y-z)\vartheta_3^2&=\vartheta_1^2(y)\vartheta_1^2(z)+\vartheta_3^2(y)\vartheta_3^2(z)\\&=\vartheta_2^2(y)\vartheta_2^2(z)-\vartheta_4(y)\vartheta_4^2(z)\end{aligned}$$

$$\begin{aligned}\vartheta_4(y+z)\vartheta_4(y-z)\vartheta_2^2&=\vartheta_4^2(y)\vartheta_2^2(z)+\vartheta_3^2(y)\vartheta_1^2(z)\\&=\vartheta_2^2(y)\vartheta_4^2(z)+\vartheta_1^2(y)\vartheta_3^2(z)\end{aligned} \tag{43}$$

$$\begin{aligned}\vartheta_4(y+z)\vartheta_4(y-z)\vartheta_3^2&=\vartheta_4^2(y)\vartheta_3^2(z)+\vartheta_2^2(y)\vartheta_1^2(z)\\&=\vartheta_3^2(y)\vartheta_4^2(z)+\vartheta_1^2(y)\vartheta_2^2(z)\end{aligned} \tag{44}$$

(Whittaker and Watson 1990, p. 488).

$$\begin{aligned}&\vartheta_1(y\pm z)\vartheta_2(y\mp z)\vartheta_3\vartheta_4\\&\quad=\vartheta_1(y)\vartheta_2(y)\vartheta_3(z)\vartheta_4(z)\pm\vartheta_3(y)\vartheta_4(y)\vartheta_1(z)\vartheta_2(z)\end{aligned} \tag{45}$$

$$\begin{aligned}&\vartheta_1(y\pm z)\vartheta_3(y\mp z)\vartheta_2\vartheta_4\\&\quad=\vartheta_1(y)\vartheta_3(y)\vartheta_2(z)\vartheta_4(z)\pm\vartheta_2(y)\vartheta_4(y)\vartheta_1(z)\vartheta_3(z)\end{aligned} \tag{46}$$

$$\begin{aligned}&\vartheta_1(y\pm z)\vartheta_4(y\mp z)\vartheta_2\vartheta_3\\&\quad=\vartheta_1(y)\vartheta_4(y)\vartheta_2(z)\vartheta_3(z)\pm\vartheta_2(y)\vartheta_3(y)\vartheta_1(z)\vartheta_4(z)\end{aligned} \tag{47}$$

$$\begin{aligned}&\vartheta_2(y\pm z)\vartheta_3(y\mp z)\vartheta_2\vartheta_3\\&\quad=\vartheta_2(y)\vartheta_3(y)\vartheta_2(z)\vartheta_3(z)\mp\vartheta_1(y)\vartheta_4(y)\vartheta_1(z)\vartheta_4(z)\end{aligned} \tag{48}$$

$$\vartheta_2(y\pm z)\vartheta_4(y\mp z)\vartheta_2\vartheta_4 = \vartheta_2(y)\vartheta_4(y)\vartheta_2(z)\vartheta_4(z)\mp\vartheta_1(y)\vartheta_3(y)\vartheta_1(z)\vartheta_3(z) \quad (49)$$

$$\vartheta_3(y\pm z)\vartheta_4(y\pm z)\vartheta_3\vartheta_4 = \vartheta_3(y)\vartheta_4(y)\vartheta_3(z)\vartheta_4(z)\mp\vartheta_1(y)\vartheta_2(y)\vartheta_1(z)\vartheta_2(z) \quad (50)$$

(Whittaker and Watson 1990, p. 488).

There are also a series of DUPLICATION FORMULAS

$$\vartheta_3(2z)\vartheta_3^3=\vartheta_3^4(z)+\vartheta_1^4(z) \quad (51)$$

$$\vartheta_2(2z)\vartheta_2\vartheta_4^2=\vartheta_2^2(z)\vartheta_4^2(z)-\vartheta_1^2(z)\vartheta_3^2(z) \quad (52)$$

$$\vartheta_3(2z)\vartheta_3\vartheta_4^2=\vartheta_3^2(z)\vartheta_4^2(z)-\vartheta_1^2(z)\vartheta_2^2(z) \quad (53)$$

$$\vartheta_4(2z)\vartheta_4^3=\vartheta_3^4(z)-\vartheta_2^4(z) \quad (54)$$

$$=\vartheta_4^4(z)-\vartheta_1^4(z) \quad (55)$$

$$\vartheta_1(2z)\vartheta_2\vartheta_3\vartheta_4=2\vartheta_1(z)\vartheta_2(z)\vartheta_3(z)\vartheta_4(z) \quad (56)$$

(Whittaker and Watson 1990, p. 488).

Ratios of Jacobi theta function derivatives to the functions themselves have the simple forms

$$\frac{\vartheta_1'(z)}{\vartheta_1(z)}=\cot z+4\sum_{n=1}^{\infty}\frac{q^{2n}}{1-q^{2n}}\sin(2nz) \quad (57)$$

$$\frac{\vartheta_2'(z)}{\vartheta_2(z)}=-\tan z+4\sum_{n=1}^{\infty}(-1)^n\frac{q^{2n}}{1-q^{2n}}\sin(2nz) \quad (58)$$

$$\frac{\vartheta_3'(z)}{\vartheta_3(z)}=4\sum_{n=1}^{\infty}(-1)^n\frac{q^{n}}{1-q^{2n}}\sin(2nz) \quad (59)$$

$$\frac{\vartheta_4'(z)}{\vartheta_4(z)}=\sum_{n=1}^{\infty}\frac{q^{2n-1}\sin(2z)}{1-2q^{2n-1}\cos(2z)+q^{4n-2}} \quad (60)$$

$$=\sum_{n=1}^{\infty}\frac{4q^n\sin(2nz)}{1-q^{2n}} \quad (61)$$

(Whittaker and Watson 1990, p. 489).

The Jacobi theta functions can be expressed as products instead of sums by

$$\vartheta_1(z)=2Gq^{1/4}\sin z\prod_{n=1}^{\infty}\left[1-2q^{2n}\cos(2z)+q^{4n}\right] \quad (62)$$

$$\vartheta_2(z)=2Gq^{1/4}\cos z\prod_{n=1}^{\infty}\left[1+2q^{2n}\cos(2z)+q^{4n}\right] \quad (63)$$

$$\vartheta_3(z)=G\prod_{n=1}^{\infty}\left[1+2q^{2n-1}\cos(2z)+q^{4n-2}\right] \quad (64)$$

$$\vartheta_4(z)=G\prod_{n=1}^{\infty}\left[1-2q^{2n-1}\cos(2z)+q^{4n-2}\right], \quad (65)$$

where

$$G\equiv\prod_{n=1}^{\infty}(1-q^{2n}) \quad (66)$$

(Whittaker and Watson 1990, pp. 469–70).

The Jacobi theta functions satisfy the PARTIAL DIFFERENTIAL EQUATION

$$\tfrac{1}{4}\pi i\frac{\partial^2 y}{\partial z^2}+\frac{\partial y}{\partial\tau}=0, \quad (67)$$

where $y\equiv\vartheta_i(z|\tau)$. Ratios of the Jacobi theta functions with ϑ_4 in the DENOMINATOR also satisfy differential equations

$$\frac{d}{dz}\left[\frac{\vartheta_1(z)}{\vartheta_4(z)}\right]=\vartheta_4^2\frac{\vartheta_2(z)\vartheta_3(z)}{\vartheta_4^2(z)} \quad (68)$$

$$\frac{d}{dz}\left[\frac{\vartheta_2(z)}{\vartheta_4(z)}\right]=-\vartheta_3^2\frac{\vartheta_1(z)\vartheta_3(z)}{\vartheta_4^2(z)} \quad (69)$$

$$\frac{d}{dz}\left[\frac{\vartheta_3(z)}{\vartheta_4(z)}\right]=\vartheta_2^2\frac{\vartheta_1(z)\vartheta_2(z)}{\vartheta_4^2(z)} \quad (70)$$

JACOBI'S IMAGINARY TRANSFORMATION expresses $\vartheta_i(z/\tau|-1/\tau)$ in terms of $\vartheta_i(z|\tau)$. There are a large number of beautiful identities involving Jacobi theta functions of arguments w, x, y, and z and w', x', y', and z', related by

$$2w'=-w+x+y+z \quad (71)$$

$$2x'=w-x-y+z \quad (72)$$

$$2y'=w+x-y+z \quad (73)$$

$$2z'=w+x+y-z \quad (74)$$

(Whittaker and Watson 1990, pp. 467–69, 488, and 490). Using the notation

$$\vartheta_i(w+\pi/2,q)\vartheta_j(x+\pi/2,q)\vartheta_k(y,q)\vartheta_l(z,q)\equiv[ijkl] \quad (75)$$

$$\vartheta_i(w',q)\vartheta_j(x',q)\vartheta_k(y'+\pi/2,q)\vartheta_l(z'+\pi/2,q)\equiv ijkl, \quad (76)$$

gives a whopping 288 identities of the form

$$\pm[a_1a_2a_3a_4]\pm[b_1b_2b_3b_4]=\pm a_1'a_2'a_3'a_4'\pm b_1'b_2'b_3'b_4'. \quad (77)$$

The complete ELLIPTIC INTEGRALS OF THE FIRST and SECOND KINDS can be expressed using Jacobi theta functions. Let

$$\xi\equiv\frac{\vartheta_1(z)}{\vartheta_4(z)}, \quad (78)$$

and plug into (68)

$$\left(\frac{d\xi}{dz}\right)^2=(\vartheta_2^2-\xi^2\vartheta_3^2)(\vartheta_3^2-\xi^2\vartheta_2^2). \quad (79)$$

Now write

$$\xi \frac{\vartheta_3}{\vartheta_2} \equiv y \tag{80}$$

and

$$z\vartheta_3^2 \equiv u. \tag{81}$$

Then

$$\left(\frac{dy}{du}\right)^2 = (1-y^2)(1-k^2y^2), \tag{82}$$

where the MODULUS is defined by

$$k = k(q) = \frac{\vartheta_2^2(q)}{\vartheta_3^2(q)}. \tag{83}$$

Define also the complementary MODULUS

$$k' = k'(q) = \frac{\vartheta_4^2(-q)}{\vartheta_3^2(q)}. \tag{84}$$

Now, since

$$\vartheta_2^4 + \vartheta_4^4 = \vartheta_3^4, \tag{85}$$

we have shown

$$k^2 + k'^2 = 1. \tag{86}$$

The solution to the equation is

$$y = \frac{\vartheta_3}{\vartheta_2} \frac{\vartheta_1(u\vartheta_3^{-2}|r)}{\vartheta_4(u\vartheta_3^{-2}|r)} \equiv \operatorname{sn}(u,k), \tag{87}$$

which is a JACOBI ELLIPTIC FUNCTION with periods

$$4K(k) = 2\pi\vartheta_3^2(q) \tag{88}$$

and

$$2iK'(k) = \pi r\vartheta_3^2(q). \tag{89}$$

Here, K is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND,

$$K(k) = \tfrac{1}{2}\pi\vartheta_3^2(q). \tag{90}$$

The Jacobi theta functions provide analytic solutions to many tricky problems in mathematics and mathematical physics. For example, the Jacobi theta functions are related to the SUM OF SQUARES FUNCTION $r_2(n)$ giving the number of representations of n by two squares via

$$\vartheta_3^2(q) = \sum_{n=0}^{\infty} r_2(n)q^n \tag{91}$$

$$\vartheta_4^2(q) = \sum_{n=0}^{\infty} (-1)^n r_2(n)q^n \tag{92}$$

(Borwein and Borwein 1987, p. 34). The general QUINTIC EQUATION is solvable in terms of Jacobi theta functions, and these functions also provide a uniformly convergent form of the GREEN'S FUNCTION for a rectangular region (Oberhettinger and Magnus 1949). Finally, Jacobi theta functions can be used to uniformize all elliptic and hyperelliptic curves, the classical example being

$$y^2 - x(x^4-1) = 0, \tag{93}$$

with

$$x = -\frac{\vartheta_3(0|\tfrac{1}{2}\tau)}{\vartheta_4(0|\tfrac{1}{2}\tau)} \tag{94}$$

$$y = \frac{i\vartheta_3^{1/2}(0|\tfrac{1}{2}\tau)\vartheta_2^2(0|\tfrac{1}{2}\tau)}{\vartheta_4^{5/2}(0|\tfrac{1}{2}\tau)}. \tag{95}$$

Jacobi Transformation

JACOBI METHOD

Jacobi Triple Product

The Jacobi triple product is the beautiful identity

$$\prod_{n=1}^{\infty}(1-x^{2n})(1+x^{2n-1}z^2)\left(1+\frac{x^{2n-1}}{z^2}\right) = \sum_{m=-\infty}^{\infty} x^{m^2}z^{2m}. \tag{1}$$

In terms of the Q-FUNCTION, (1) is written

$$Q_1Q_2Q_3 = 1, \tag{2}$$

which is one of the two JACOBI IDENTITIES. In q-SERIES notation, the Jacobi triple product identity is written

$$(q,-xq,-1/x;q)_\infty = \sum_{k=-\infty}^{\infty} x^k q^{(k^2+k)/2} \tag{3}$$

for $0<|q|<1$ and $x \neq 0$ (Gasper and Rahman 1990, p. 12; Leininger and Milne 1997). Another form of the identity is

$$\sum_{n=-\infty}^{\infty}(-1)^n a^n q^{(n^2-n)/2} = \prod_{n=1}^{\infty}(1-aq^{n-1})(1-a^{-1}q^n)(1-q^n) \tag{4}$$

(Hirschhorn 1999).

Dividing (4) by $1-a$ and letting $a \to 1$ gives the limiting case

$$(q,q)_\infty^3 = \sum_{n=0}^{\infty}(-1)^n(2n+1)q^{n(n+1)/2} \tag{5}$$

$$= \tfrac{1}{2}\sum_{n=-\infty}^{\infty}(-1)^n(2n+1)q^{n(n+1)/2} \tag{6}$$

(Jacobi 1829; Hardy and Wright 1979; Leininger and Milne 1997; Hardy 1999, p. 87; Hirschhorn 1999).

For the special case of $z=1$, (1) becomes

$$\varphi(x) \equiv G(1) = \prod_{n=1}^{\infty}(1+x^{2n-1})^2(1-x^{2n}) = \sum_{m=-\infty}^{\infty} x^{m^2} = 1 + 2\sum_{m=1}^{\infty} x^{m^2}, \tag{7}$$

where $\varphi(x)$ is the one-variable RAMANUJAN THETA FUNCTION. In terms of the two-variable RAMANUJAN THETA FUNCTION $f(a,b)$, the Jacobi triple product is equivalent to

$$f(a,b) = (-a;ab)_\infty(-b;ab)_\infty(ab;ab)_\infty \tag{8}$$

(Berndt *et al.*).

One method of proof for the Jacobi identity proceeds by defining the function

$$F(z) \equiv \prod_{n=1}^{\infty}(1+x^{2n-1}z^2)\left(1+\frac{x^{2n-1}}{z^2}\right) = (1+xz^2)\left(1+\frac{x}{z^2}\right)(1+x^3z^2)\left(1+\frac{x^3}{z^2}\right)(1+x^5z^2) \times \left(1+\frac{x^5}{z^2}\right)\cdots, \tag{9}$$

Then

$$F(xz) = (1+x^3z^2)\left(1+\frac{1}{xz^2}\right)(1+x^5z^2)\left(1+\frac{x}{z^2}\right) \times (1+x^7z^2)\left(1+\frac{x^3}{z^2}\right)\cdots. \tag{10}$$

Taking (10) ÷ (9),

$$\frac{F(xz)}{F(z)} = \left(1+\frac{1}{xz^2}\right)\left(\frac{1}{1+xz^2}\right) = \frac{xz^2+1}{xz^2}\,\frac{1}{1+xz^2} = \frac{1}{xz^2}, \tag{11}$$

which yields the fundamental relation

$$xz^2F(xz) = F(z). \tag{12}$$

Now define

$$G(z) \equiv F(z)\prod_{n=1}^{\infty}(1-x^{2n}) \tag{13}$$

$$G(xz) = F(xz)\prod_{n=1}^{\infty}(1-x^{2n}). \tag{14}$$

Using (12), (14) becomes

$$G(xz) = \frac{F(z)}{xz^2}\prod_{n=1}^{\infty}(1-x^{2n}) = \frac{G(z)}{xz^2}, \tag{15}$$

so

$$G(z) = xz^2 G(xz). \quad (16)$$

Expand G in a LAURENT SERIES. Since G is an EVEN FUNCTION, the LAURENT SERIES contains only even terms.

$$G(z) = \sum_{m=-\infty}^{\infty} a_m z^{2m}. \quad (17)$$

Equation (16) then requires that

$$\sum_{m=-\infty}^{\infty} a_m z^{2m} = xz^2 \sum_{m=-\infty}^{\infty} a_m (xz)^{2m}$$

$$= \sum_{m=-\infty}^{\infty} a_m x^{2m+1} z^{2m+2}. \quad (18)$$

This can be re-indexed with $m' \equiv m-1$ on the left side of (18)

$$\sum_{m=-\infty}^{\infty} a_m z^{2m} = \sum_{m=-\infty}^{\infty} a_m x^{2m-1} z^{2m}, \quad (19)$$

which provides a RECURRENCE RELATION

$$a_m = a_{m-1} x^{2m-1}, \quad (20)$$

so

$$a_1 = a_0 x \quad (21)$$

$$a_2 = a_1 x^3 = a_0 x^{3+1} = a_0 x^4 = a_0 x^{2^2} \quad (22)$$

$$a_3 = a_2 x^5 = a_0 x^{5+4} = a_0 x^9 = a_0 x^{3^2}. \quad (23)$$

The exponent grows greater by $(2m-1)$ for each increase in m of 1. It is given by

$$\sum_{n=1}^{m} (2m-1) = 2\frac{m(m+1)}{2} - m = m^2. \quad (24)$$

Therefore,

$$a_m = a_0 x^{m^2}. \quad (25)$$

This means that

$$G(z) = a_0 \sum_{m=-\infty}^{\infty} x^{m^2} z^{2m}. \quad (26)$$

The COEFFICIENT a_0 must be determined by going back to (9) and (13) and letting $z = 1$. Then

$$F(1) = \prod_{n=1}^{\infty} (1 + x^{2n-1})(1 + x^{2n-1})$$

$$= \prod_{n=1}^{\infty} (1 + x^{2n-1})^2 \quad (27)$$

$$G(1) = F(1) \prod_{n=1}^{\infty} (1 - x^{2n})$$

$$= \prod_{n=1}^{\infty} (1 + x^{2n-1})^2 \prod_{n=1}^{\infty} (1 - x^{2n})$$

$$= \prod_{n=1}^{\infty} (1 + x^{2n-1})^2 (1 - x^{2n}), \quad (28)$$

since multiplication is ASSOCIATIVE. It is clear from this expression that the a_0 term must be 1, because all other terms will contain higher POWERS of x. Therefore,

$$a_0 = 1, \quad (29)$$

so we have the Jacobi triple product,

$$G(z) = \prod_{n=1}^{\infty} (1 - x^{2n})(1 + x^{2n-1} z^2)\left(1 + \frac{x^{2n-1}}{z^2}\right)$$

$$= \sum_{m=-\infty}^{\infty} x^{m^2} z^{2m}. \quad (30)$$

Jacobi Zeta Function

Denoted $\mathrm{zn}(u,k)$ or $Z(u)$.

$$Z(\phi|m) \equiv E(\phi|m) - \frac{E(m)F(\phi|m)}{K(m)},$$

where ϕ is the AMPLITUDE, m is the PARAMETER, and $F(\phi|m)$ and $K(m)$ are ELLIPTIC INTEGRALS OF THE FIRST KIND, and $e(m)$ is an ELLIPTIC INTEGRAL OF THE SECOND KIND. See Gradshteyn and Ryzhik (2000, p. xxxi) for expressions in terms of THETA FUNCTIONS. The Jacobi zeta functions is implemented in *Mathematica* as `JacobiZeta[`*phi*, *m*`]`.

Jacobi's Curvature Theorem

The principal normal indicatrix of a closed SPACE CURVE with nonvanishing curvature bisects the AREA of the unit sphere if it is embedded.

Jacobi's Determinant Identity

Let

$$\mathsf{A} = \begin{bmatrix} \mathsf{B} & \mathsf{D} \\ \mathsf{E} & \mathsf{C} \end{bmatrix} \qquad (1)$$

$$\mathsf{A}^{-1} = \begin{bmatrix} \mathsf{W} & \mathsf{X} \\ \mathsf{Y} & \mathsf{Z} \end{bmatrix}, \qquad (2)$$

where B and W are $k \times k$ MATRICES. Then

$$(\det \mathsf{Z})(\det \mathsf{A}) = \det \mathsf{B}. \qquad (3)$$

The proof follows from equating determinants on the two sides of the block matrices

$$\begin{bmatrix} \mathsf{B} & \mathsf{D} \\ \mathsf{E} & \mathsf{C} \end{bmatrix}\begin{bmatrix} \mathsf{I} & \mathsf{X} \\ \mathsf{O} & \mathsf{Z} \end{bmatrix} = \begin{bmatrix} \mathsf{B} & \mathsf{O} \\ \mathsf{E} & \mathsf{I} \end{bmatrix}, \qquad (4)$$

where I is the IDENTITY MATRIX and O is the ZERO MATRIX.

Jacobi's Imaginary Transformation

Transformations which relate elliptic functions to other elliptic functions of the same type but having different arguments. In the case of the JACOBI ELLIPTIC FUNCTIONS $\mathrm{sn}\, u$, $\mathrm{cn}\, u$, and $\mathrm{dn}\, u$, the transformations are

$$\mathrm{sn}(iu,k) = i\frac{\mathrm{sn}(u,k')}{\mathrm{cn}(u,k')} \qquad (1)$$

$$\mathrm{cn}(iu,k) = \frac{1}{\mathrm{cn}(u,k')} \qquad (2)$$

$$\mathrm{dn}(iu,k) = \frac{\mathrm{dn}(u,k')}{\mathrm{cn}(u,k')}, \qquad (3)$$

where k is the MODULUS, and $k' = \sqrt{1-k^2}$ is the COMPLEMENTARY MODULUS (Abramowitz and Stegun 1972; Whittaker and Watson 1990, p. 505).

In the case of the JACOBI THETA FUNCTIONS, Jacobi's imaginary transformation gives

$$\vartheta_1(z|\tau) = -i(-i\tau)^{-1/2} e^{i\tau' z^2/\pi} \vartheta_1(z\tau'|\tau') \qquad (4)$$

$$\vartheta_2(z|\tau) = (-i\tau)^{-1/2} e^{i\tau' z^2/\pi} \vartheta_4(z\tau'|\tau') \qquad (5)$$

$$\vartheta_3(z|\tau) = (-i\tau)^{-1/2} e^{i\tau' z^2/\pi} \vartheta_3(z\tau'|\tau') \qquad (6)$$

$$\vartheta_4(z|\tau) = (-i\tau)^{-1/2} e^{i\tau' z^2/\pi} \vartheta_2(z\tau'|\tau), \qquad (7)$$

where

$$\tau' \equiv -\frac{1}{\tau'} \qquad (8)$$

and $(-i\tau)^{-1/2}$ is interpreted as satisfying $|\arg(-i\tau)| < \pi/2$ (Whittaker and Watson 1990, p. 475). These transformations were first obtained by Jacobi (1828), but Poisson (1827) had previously obtained a formula equivalent to one of the four, and from which the other three follow from elementary algebra (Whittaker and Watson 1990, p. 475).

Whittaker, E. T. and Watson, G. N. "Jacobi's Imaginary Transformation." §21.51 in *A Course in Modern Analysis, 4th ed.* Cambridge, England: Cambridge University Press, pp. 474–76 and 505, 1990.

Jacobi's Theorem

Let M_r be an r-rowed MINOR of the nth order DETERMINANT $|\mathsf{A}|$ associated with an $n \times n$ MATRIX $\mathsf{A} = a_{ij}$ in which the rows i_1, i_2, ..., i_r are represented with columns k_1, k_2, ..., k_r. Define the complementary minor to M_r as the $(n-k)$-rowed MINOR obtained from $|\mathsf{A}|$ by deleting all the rows and columns associated with M_r and the signed complementary minor $M^{(r)}$ to M_r to be

$$M^{(r)} = (-1)^{i_1+i_2+\ldots+i_r+k_1+k_2+\ldots+k_r} \times [\text{complementary minor to } M_r].$$

Let the MATRIX of cofactors be given by

$$\Delta = \begin{vmatrix} A_{11} & A_{12} & \cdots & A_{1n} \\ A_{21} & A_{22} & \cdots & A_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ A_{n1} & A_{n2} & \cdots & A_{nn} \end{vmatrix},$$

with M_r and M'_r the corresponding r-rowed minors of $|\mathsf{A}|$ and Δ, then it is true that

$$M'_r = |\mathsf{A}|^{r-1} M^{(r)}.$$

JacobiAmplitude

AMPLITUDE

Jacobian

Given a set $\mathbf{y} = \mathbf{f}(\mathbf{x})$ of n equations in n variables x_1, ..., x_n, written explicitly as

$$\mathbf{y} \equiv \begin{bmatrix} f_1(\mathbf{x}) \\ f_2(\mathbf{x}) \\ \vdots \\ f_n(\mathbf{x}) \end{bmatrix}, \qquad (1)$$

or more explicitly as

$$\begin{cases} y_1 = f_1(x_1, \ldots, x_n) \\ \vdots \\ y_n = f_n(x_1, \ldots, x_n), \end{cases} \qquad (2)$$

the Jacobian matrix, sometimes simply called "the Jacobian" (Simon and Blume 1994) is defined by

$$\mathsf{J}(x_1, \ldots, x_n) = \begin{bmatrix} \frac{\partial y_1}{\partial x_1} & \cdots & \frac{\partial y_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial y_n}{\partial x_1} & \cdots & \frac{\partial y_n}{\partial x_n} \end{bmatrix}. \qquad (3)$$

The Jacobian matrix can be computed using the *Mathematica* command

```
JacobianMatrix[fns_List, vars_List] :=
   Outer[D, fns, vars]
```

The DETERMINANT of J is the Jacobian determinant (confusingly, often called "the Jacobian" as well) and is denoted

$$J = \left| \frac{\partial(y_1, \ldots, y_n)}{\partial(x_1, \ldots, x_n)} \right|. \qquad (4)$$

It can be computed using the *Mathematica* command

```
JacobianDeterminant[fns_List,  vars_List]  :=
Module[
   {
    nf  =  Length[fns],
    nv  =  Length[vars],
    j  =  JacobianMatrix[fns, vars]
   },
   Which[
    nf  >  nv, Sqrt[Det[Transpose[j].j]],
    nf  = =  nv, Det[j],
    nf  <  nv, Sqrt[Det[j.Transpose[j]]]
   ]
 ]
```

Taking the differential

$$d\mathbf{y} = \mathbf{y}_{\mathbf{x}} d\mathbf{x} \qquad (5)$$

shows that J is the DETERMINANT of the MATRIX $\mathbf{y}_{\mathbf{x}}$, and therefore gives the ratios of n-D volumes (CONTENTS) in y and x,

$$dy_1 \cdots dy_n = \left| \frac{\partial(y_1, \ldots, y_n)}{\partial(x_1, \ldots, x_n)} \right| dx_1 \cdots dx_n. \qquad (6)$$

The concept of the Jacobian can also be applied to n functions in more than n variables. For example, considering $f(u, v, w)$ and $g(u, v, w)$, the Jacobians

$$\frac{\partial(f, g)}{\partial(u, v)} = \begin{vmatrix} f_u & f_v \\ g_u & g_v \end{vmatrix} \qquad (7)$$

$$\frac{\partial(f, g)}{\partial(u, w)} = \begin{vmatrix} f_u & f_w \\ g_u & g_w \end{vmatrix} \qquad (8)$$

can be defined (Kaplan 1984, p. 99).

For the case of $n = 3$ variables, the Jacobian takes the special form

$$Jf(x_1, x_2, x_3) \equiv \left| \frac{\partial \mathbf{y}}{\partial x_1} \cdot \frac{\partial \mathbf{y}}{\partial x_2} \times \frac{\partial \mathbf{y}}{\partial x_3} \right|, \qquad (9)$$

where $\mathbf{a}\cdot\mathbf{b}$ is the DOT PRODUCT and $\mathbf{b}\times\mathbf{c}$ is the CROSS PRODUCT, which can be expanded to give

$$\left|\frac{\partial(y_1,y_2,y_3)}{\partial(x_1,x_2,x_3)}\right|=\begin{vmatrix}\frac{\partial y_1}{\partial x_1} & \frac{\partial y_1}{\partial x_2} & \frac{\partial y_1}{\partial x_3}\\ \frac{\partial y_2}{\partial x_1} & \frac{\partial y_2}{\partial x_2} & \frac{\partial y_2}{\partial x_3}\\ \frac{\partial y_3}{\partial x_1} & \frac{\partial y_3}{\partial x_2} & \frac{\partial y_3}{\partial x_3}\end{vmatrix}. \tag{10}$$

Jacobi-Gauss Quadrature

Also called JACOBI QUADRATURE or MEHLER QUADRATURE. A GAUSSIAN QUADRATURE over the interval $[-1,1]$ with WEIGHTING FUNCTION

$$W(x)=(1-x)^\alpha(1+x)^\beta. \tag{1}$$

The ABSCISSAS for quadrature order n is given by the roots of the JACOBI POLYNOMIALS $P_n^{(\alpha,\beta)}(x)$. The weights are

$$\begin{aligned} w_i &= -\frac{A_{n+1}\gamma_n}{A_n P_n^{(\alpha,\beta)\prime}(x_i)P_{n+1}^{(\alpha,\beta)}(x_i)} \\ &= \frac{A_n}{A_{n-1}}\frac{\gamma_{n-1}}{P_{n-1}^{(\alpha,\beta)}(x_i)P_n^{(\alpha,\beta)\prime}(x_i)}, \end{aligned} \tag{2}$$

where A_n is the COEFFICIENT of x^n in $P_n^{(\alpha,\beta)}(x)$. For JACOBI POLYNOMIALS,

$$A_n \frac{\Gamma(2n+\alpha+\beta+1)}{2^n n!\Gamma(n+\alpha+\beta+1)}, \tag{3}$$

where $\Gamma(z)$ is a GAMMA FUNCTION. Additionally,

$$\gamma_n = \frac{1}{2^{2n}(n!)^2} \frac{2^{2n+\alpha+\beta+1}n!}{2n+\alpha+\beta+1} \times \frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}{\Gamma(n+\alpha+\beta+1)}, \tag{4}$$

so

$$w_i = \frac{2n+\alpha+\beta+2}{n+\alpha+\beta+1} \frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}{\Gamma(n+\alpha+\beta+1)} \times \frac{2^{2n+\alpha+\beta+1}n!}{V'_n(x_i)V_{n+1}(x_i)} \tag{5}$$

$$= \frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}{\Gamma(n+\alpha+\beta+1)} \frac{2^{2n+\alpha+\beta+1}n!}{(1-x_i^2)[V'_n(x_i)]^2}, \tag{6}$$

where

$$V_m \equiv P_n^{(\alpha,\beta)}(x) \frac{2^n n!}{(-1)^n}. \tag{7}$$

The error term is

$$E_n = \frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)\Gamma(n+\alpha+\beta+1)}{(2n+\alpha+\beta+1)[\Gamma(2n+\alpha+\beta+1)]^2} \times \frac{2^{2n+\alpha+\beta+1}n!}{(2n)!} f^{(2n)}(\xi) \tag{8}$$

(Hildebrand 1959).

Jacobson Canonical Form

Let A be a matrix with the elementary divisors of its characteristic matrix expressed as powers of its irreducible polynomials in the field $F[\lambda]$, and consider an elementary divisor $[p(\lambda)]^q$. If $q > 1$, then

$$C_q(p) = \begin{bmatrix} C(p) & M & 0 & \cdots & 0 & 0 \\ 0 & C(p) & M & \cdots & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & C(p) & M \\ 0 & 0 & 0 & \cdots & 0 & C(p) \end{bmatrix},$$

where M is a matrix of the same order as $C(p)$ having the element 1 in the lower left-hand corner and zeros everywhere else.

Ayres, F. Jr. *Theory and Problems of Matrices.* New York: Schaum, pp. 205–06, 1962.

Jacobson Radical
A special ideal in a COMMUTATIVE RING R. The Jacobson radical is the intersection of the maximal ideals in R. It could be the zero ideal, as in the case of the integers.

See also ALGEBRAIC GEOMETRY, ALGEBRAIC NUMBER THEORY, IDEAL, NILRADICAL, RADICAL (IDEAL)

Jacobsthal Number
The Jacobsthal numbers are the numbers obtained by the U_ns in the LUCAS SEQUENCE with $P=1$ and $Q=-2$, corresponding to $a=2$ and $b=-1$. They and the Jacobsthal-Lucas numbers (the V_ns) satisfy the RECURRENCE RELATION

$$J_n = J_{n-1} + 2J_{n-2}. \tag{1}$$

The Jacobsthal numbers satisfy $J_0 = 0$ and $J_1 = 1$ and are 0, 1, 1, 3, 5, 11, 21, 43, 85, 171, 341, ... (Sloane's A001045). The Jacobsthal-Lucas numbers satisfy $j_0 = 2$ and $j_1 = 1$ and are 2, 1, 5, 7, 17, 31, 65, 127, 257, 511, 1025, ... (Sloane's A014551). The properties of these numbers are summarized in Horadam (1996). They are given by the closed form expressions

$$J_n = \sum_{r=0}^{[(n-1)/2]} \binom{n-1-r}{r} 2^r \tag{2}$$

$$j_n = \sum_{r=0}^{\lfloor n/2 \rfloor} \frac{n}{n-r} \binom{n-r}{r} 2^r, \tag{3}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The Binet forms are

$$J_n = \tfrac{1}{3}(a^n - b^n) = \tfrac{1}{3}[2^n - (-1)^n] \tag{4}$$

$$j_n = a^n + b^n = 2^n + (-1)^n. \tag{5}$$

The GENERATING FUNCTIONS are

$$\sum_{i=1}^{\infty} J_i x^{i-1} = (1 - x - 2x^2)^{-1} \tag{6}$$

$$\sum_{i=1}^{\infty} j_i x^{i-1} = (1+4x)(1 - x - 2x^2)^{-1}. \tag{7}$$

The Simson FORMULAS are

$$J_{n+1}J_{n-1} - J_n^2 = (-1)^n 2^{n-1} \tag{8}$$

$$j_{n+1}j_{n-1} - j_n^2 = 9(-1)^{n-1}2^{n-1} = -9(J_{n+1}J_{n-1} - J_n^2). \tag{9}$$

Summation FORMULAS include

$$\sum_{i=2}^{n} J_i = \tfrac{1}{2}(J_{n+2} - 3). \tag{10}$$

$$\sum_{i=1}^{n} j_i = \tfrac{1}{2}(j_{n+2} - 5). \tag{11}$$

Interrelationships are

$$j_n J_n = J_{2n} \tag{12}$$

$$j_n = J_{n+1} + 2J_{n-1} \tag{13}$$

$$9J_n = j_{n+1} + 2j_{n-1} \tag{14}$$

$$j_{n+1} + j_n = 3(J_{n+1} + J_n) = 3 \cdot 2^n \tag{15}$$

$$\begin{aligned} j_{n+1} - j_n &= 3(J_{n+1} - J_n) + 4(-1)^{n+1} \\ &= 2^n + 2(-1)^{n+1} \end{aligned} \tag{16}$$

$$j_{n+1} - 2j_n = 3(2J_n - J_{n+1}) = 3(-1)^{n+1} \tag{17}$$

$$2j_{n+1} + j_{n-1} = 3(2J_{n+1} + J_{n-1}) + 6(-1)^{n+1} \tag{18}$$

$$j_{n+r} + j_{n-r} = 3(J_{n+r} + J_{n-r}) + 4(-1)^{n-r} \tag{19}$$

$$= 2^{n-r}(2^{2r} + 1) + 2(-1)^{n-r} \tag{20}$$

$$j_{n+r} - j_{n-r} = 3(J_{n+r} - J_{n-r}) = 2^{n-r}(2^{2r} - 1) \tag{21}$$

$$j_n = 3J_n + 2(-1)^n \tag{22}$$

$$3J_n + j_n = 2^{n+1} \tag{23}$$

$$J_n + j_n = 2J_{n+1} \tag{24}$$

$$j_{n+2}j_{n-2} - j_n^2 = -9(J_{n+2}J_{n-2} - J_n)^2 = 9(-1)^n 2^{n-2} \tag{25}$$

$$J_m j_n + J_n j_m = 2J_{m+n} \tag{26}$$

$$j_m j_n + 9J_m J_n = 2j_{m+n} \tag{27}$$

$$j_n^2 + 9J_n^2 = 2j_{2n} \tag{28}$$

$$J_m j_n - J_n j_m = (-1)^n 2^{n+1} J_{m-n} \tag{29}$$

$$j_m j_n - 9J_m J_n = (-1)^n 2^{n+1} j_{m-n} \tag{30}$$

$$j_n^2 - 9J_n^2 = (-1)^n 2^{n+2} \tag{31}$$

(Horadam 1996).

Jacobsthal Polynomial

The Jacobsthal polynomials are the POLYNOMIALS obtained by setting $p(x) = 1$ and $q(x) = 2x$ in the LUCAS POLYNOMIAL SEQUENCE. The first few Jacobsthal polynomials are

$$J_1(x) = 1$$

$$J_2(x) = 1$$

$$J_3(x) = 1 + 2x$$

$$J_4(x) = 1 + 4x$$

$$J_5(x) = 4x^2 + 6x + 1,$$

and the first few Jacobsthal-Lucas polynomials are

$$j_1(x) = 1$$

$$j_2(x) = 4x + 1$$

$$j_3(x) = 6x + 1$$

$$j_4(x) = 8x^2 + 8x + 1$$

$$j_5(x) = 20x^2 + 10x + 1.$$

Jacobsthal and Jacobsthal-Lucas polynomials satisfy

$$J_n(1) = J_n$$

$$j_n(1) = j_n$$

where J_n is a JACOBSTHAL NUMBER and j_n is a JACOBSTHAL-LUCAS NUMBER.

Japanese Temple Problem

SANGAKU PROBLEM

Japanese Theorem

Let a convex CYCLIC POLYGON be TRIANGULATED in any manner, and draw the INCIRCLE to each TRIANGLE so constructed. Then the sum of the INRADII is a constant independent of the TRIANGULATION chosen. This theorem can be proved using CARNOT'S THEOREM. In the above figures, for example, the INRADII of the left triangulation are 0.142479, 0.156972, 0.232307, 0.498525, and the INRADII of the right triangulation are 0.157243, 0.206644, 0.312037, 0.354359, giving a sum of 1.03028 in each case.

According to an ancient custom of Japanese mathematicians, this theorem was a SANGAKU PROBLEM inscribed on tablets hung in a Japanese temple to honor the gods and the author in 1800 (Johnson 1929).

The converse is also true: if the sum of INRADII does not depend on the TRIANGULATION of a POLYGON, then the POLYGON is CYCLIC.

FREY CURVE

Jeep Problem

Maximize the distance a jeep can penetrate into the desert using a given quantity of fuel. The jeep is allowed to go forward, unload some fuel, and then return to its base using the fuel remaining in its tank. At its base, it may refuel and set out again. When it reaches fuel it has previously stored, it may then use it to partially fill its tank. This problem is also called the EXPLORATION PROBLEM (Ball and Coxeter 1987).

Given $n + f$ (with $0 \leq f < 1$) drums of fuel at the edge of the desert and a jeep capable of holding one drum (and storing fuel in containers along the way), the maximum one-way distance which can be traveled (assuming the jeep travels one unit of distance per drum of fuel expended) is

$$d = \frac{f}{2n+1} + \sum_{i=1}^{n} \frac{1}{2i-1}$$

$$= \frac{f}{2n+1} + \tfrac{1}{2}\left[\gamma + 2\ln 2 + \psi_0\left(\tfrac{1}{2} + n\right)\right],$$

where γ is the EULER-MASCHERONI CONSTANT and $\psi_n(z)$ the POLYGAMMA FUNCTION.

For example, the farthest a jeep with $n = 1$ drum can travel is obviously 1 unit. However, with $n = 2$ drums of gas, the maximum distance is achieved by filling up the jeep's tank with the first drum, traveling 1/3 of a

unit, storing 1/3 of a drum of fuel there, and then returning to base with the remaining 1/3 of a tank. At the base, the tank is filled with the second drum. The jeep then travels 1/3 of a unit (expending 1/3 of a drum of fuel), refills the tank using the 1/3 of a drum of fuel stored there, and continues an additional 1 unit of distance on a full tank, giving a total distance of 4/3. The solutions for $n = 1$, 2, ... drums are 1, 4/3, 23/15, 176/105, 563/315, ..., which can also be written as $a(n)/b(n)$, where

$$a(n) = \left(\frac{1}{1} + \frac{1}{3} + \ldots + \frac{1}{2n-1}\right) \operatorname{LCM}(1, 3, 5, \ldots, 2n-1)$$

$$b(n) = \operatorname{LCM}(1, 3, 5, \ldots, 2n-1)$$

(Sloane's A025550 and A025547).

Jenkins' Theorem

This entry contributed by RONALD M. AARTS

A theorem in the theory of univalent CONFORMAL MAPPINGS of families of domains on a RIEMANN SURFACE, containing an inequality for the coefficients of the mapping functions, as well as conditions to be satisfied by the function so that the inequality becomes an equality. Jenkins' theorem is an exact expression and generalization of TEICHMÜLLER'S PRINCIPLE (Jenkins 1958, Jenkins 1964).

$$f(x) = \sum_{k=0}^{\infty} \gamma_k \frac{x^k}{k!},$$

where the γ_ks are POSITIVE and satisfy TURÁN'S INEQUALITIES

$$\gamma_k^2 - \gamma_{k-1}\gamma_{k+1} \geq 0$$

for $k = 1$, 2, ... The Jensen polynomial $g(t)$ associated with $f(x)$ is then given by

$$g_n(t) = \sum_{k=0}^{n} \binom{n}{k} \gamma_k t^k,$$

where $\binom{a}{b}$ is a BINOMIAL COEFFICIENT.

Jensen's Formula

Portions of this entry contributed by RONALD M. AARTS

A relation connecting the values of a MEROMORPHIC FUNCTION inside a disk with its boundary values on the circumference and with its zeros and poles (Jensen 1899, Levin 1980). Let f be holomorphic on a NEIGHBORHOOD of the CLOSED DISK $\bar{D}(0, r)$ and $f(0) \neq 0$, a_1, ..., a_k be the zeros of f in the OPEN DISK $D(0, r)$ counted according to their multiplicities, and assume that $f \neq 0$ on $\partial D(0, r)$. Then

$$\ln|f(0)|+\sum_{j=1}^{k}\ln\left|\frac{r}{a_j}\right|=\frac{1}{2\pi}\int_0^{2\pi}\ln\left|f\left(re^{i\theta}\right)\right|d\theta$$

(Krantz 1999, p. 118).

Jensen's Inequality

For a REAL CONTINUOUS CONCAVE FUNCTION

$$\frac{\sum f(x_i)}{n}\leq f\left(\frac{\sum x_i}{n}\right) \tag{1}$$

if f is concave down,

$$\frac{\sum f(x_i)}{n}\geq f\left(\frac{\sum x_i}{n}\right) \tag{2}$$

if f is concave up, and

$$\frac{\sum f(x_i)}{n}= f\left(\frac{\sum x_i}{n}\right) \tag{3}$$

IFF $x_1=x_2=\ldots=x_n$. A special case is

$$\sqrt{x_1x_2\cdots x_n}\leq\frac{x_1+x_2+\ldots+x_n}{n}, \tag{4}$$

with equality IFF $x_1=x_2=\ldots=x_n$.

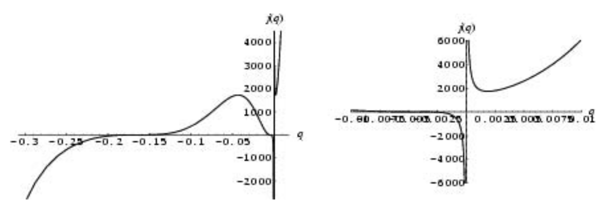
Jessen's Orthogonal Icosahedron

A SHAKY POLYHEDRON constructed by replacing six pairs of adjacent triangles in an ICOSAHEDRON (whose edges form a SKEW QUADRILATERAL) with pairs of ISOSCELES TRIANGLES sharing a common base. The polyhedron can be constructed by dividing the sides of the ICOSAHEDRON in the GOLDEN RATIO (as used in the construction of the ICOSAHEDRON along the edges of the OCTAHEDRON), but reversing the long and short segments.



The centers of the eight EQUILATERAL TRIANGLES which remain are then the vertices of a CUBE. The polyhedron can be deformed infinitesimally by pinching the angles between the isosceles triangles whose bases act as hinges. If the polyhedron is constructed using paper and tape instead of entirely rigid faces, it is possible to collapse the isosceles triangles onto one another, resulting in an OCTAHEDRON.

j-Function

The j-function is defined as

$$j(q) \equiv 1728 J(\sqrt{q}), \tag{1}$$

where

$$J(q) \equiv \frac{4}{27} \frac{[1 - \lambda(q) + \lambda^2(q)]^3}{\lambda^2(q)[1 - \lambda(q)]^2} \tag{2}$$

is KLEIN'S ABSOLUTE INVARIANT, $\lambda(q)$ the ELLIPTIC LAMBDA FUNCTION

$$\lambda(q) \equiv k^2(q) = \left[\frac{\vartheta_2(q)}{\vartheta_3(q)}\right]^4, \tag{3}$$

ϑ_i a JACOBI THETA FUNCTION, and $1728 = 12^3$. This function can also be specified in terms of the WEBER FUNCTIONS f, f_1, f_2, γ_2, and γ_3 as

$$j(z) = \frac{[f^{24}(z) - 16]^3}{f^{24}(z)} \tag{4}$$

$$= \frac{[f_1^{24}(z) + 16]^3}{f_1^{24}(z)} \tag{5}$$

$$= \frac{[f_2^{24}(z) + 16]^3}{f_2^{24}(z)} \tag{6}$$

$$= \gamma_2^3(z) \tag{7}$$

$$= \gamma_3^2(z) + 1728 \tag{8}$$

(Weber 1902, p. 179; Atkin and Morain 1993).

The j-function is a MEROMORPHIC FUNCTION on the UPPER HALF-PLANE which is invariant with respect to

the SPECIAL LINEAR GROUP $SL(2, Z)$. It has a FOURIER SERIES

$$j(q) = \sum_{n=-\infty}^{\infty} c_n q^n, \tag{9}$$

for the NOME

$$q \equiv e^{2\pi i \tau} \tag{10}$$

with $\Im[\tau] > 0$. The coefficients in the expansion of the j-function satisfy:

1. $c_n = 0$ for $n < -1$ and $c_{-1} = 1$,
2. all c_ns are INTEGERS with fairly limited growth with respect to n, and
3. $j(q)$ is an ALGEBRAIC NUMBER, sometimes a RATIONAL NUMBER, and sometimes even an INTEGER at certain very special values of q (or τ).

The latter result is the end result of the massive and beautiful theory of COMPLEX multiplication and the first step of Kronecker's so-called "JUGENDTRAUM."

Then all of the COEFFICIENTS in the LAURENT SERIES

$$j(q) = \frac{1}{q} + 744 + 196884q + 21493760q^2 + 864299970q^3 + 20245856256q^4 + 333202640600q^5 + \ldots \tag{11}$$

(Sloane's A000521) are POSITIVE INTEGERS (Rankin 1977, Apostol 1997). Berwick calculated the first seven $c(n)$ in 1916, Zuckerman found the first 24 in 1939, and van Wijngaarden gave the first 100 in 1963.

Some remarkable sum formulas involving $j(q)$ for $\tau \in H$, where H is the UPPER HALF-PLANE, and $c(n)$ include

$$\left[504 \sum_{n=0}^{\infty} \sigma_5(n) q^n\right]^2 = \left[j(q) - 12^3\right] \sum_{n=1}^{\infty} \tau(n) x^n, \tag{12}$$

where $\sigma_k(n)$ is the DIVISOR FUNCTION and $\sigma_5(0) = -1/504$. In addition,

$$(504)^2 \sum_{k=0}^{n} \sigma_5(k)\sigma_5(n-k) = \tau(n+1) - 984\tau(n) + \sum_{k=1}^{n-1} c(k)\tau(n-k) \tag{13}$$

$$\frac{65520}{691}[\sigma_{11}(n) - \tau(n)] = \tau(n+1) + 24\tau(n) + \sum_{k=1}^{n-1} c(k)\tau(n-k), \tag{14}$$

where $\tau(n)$ is the TAU FUNCTION (Lehmer 1942; Apostol 1997, p. 92). The latter leads immediately to the remarkable congruence

$$\tau(n) \equiv \sigma_{11}(n) \pmod{691}. \tag{15}$$

Lehmer (1942) showed that

$$(n+1)c(n) \equiv 0 \pmod{24} \tag{16}$$

for all $n \geq 1$, and Lehner (1949) and Apostol (1997, pp. 22, 74, and 90–1) demonstrated that

$$c(2n) \equiv 0 \pmod{2^{11}} \tag{17}$$

$$c(3n) \equiv 0 \pmod{3^5} \tag{18}$$

$$c(5n) \equiv 0 \pmod{5^2} \tag{19}$$

$$c(7n) \equiv 0 \pmod{7} \tag{20}$$

$$c(11n) \equiv 0 \pmod{11}. \tag{21}$$

More generally,

$$c(2^\alpha n) \equiv 0 \pmod{2^{3\alpha+8}} \tag{22}$$

$$c(3^\alpha n) \equiv 0 \pmod{3^{2\alpha+3}} \tag{23}$$

$$c(5^\alpha n) \equiv 0 \pmod{5^{\alpha+1}} \tag{24}$$

$$c(7^\alpha n) \equiv 0 \pmod{7^\alpha} \tag{25}$$

(Lehner 1949; Apostol 1997, p. 91). Congruences of this type cannot exist for 13, but Newman (1958) showed

$$c(13np) + c(13n)c(13p) + p^{-1}c\left(\frac{13n}{p}\right) \equiv 0 \pmod{13}, \tag{26}$$

where $p^{-1}p \equiv 1 \pmod{13}$ and $c(x) = 0$ if x is not an integer (Apostol 1997, p. 91). Congruences for $c(kn)$ have been generalized by Atkin and O'Brien (1967).

An asymptotic formula for $c(n)$ was discovered by Petersson (1932), and subsequently independently rediscovered by Rademacher (1938):

$$c(n) \sim \frac{e^{4\pi\sqrt{n}}}{\sqrt{2}n^{3/4}}. \tag{27}$$

Let d be a POSITIVE SQUAREFREE INTEGER, and define

$$t \equiv \begin{cases} i\sqrt{d} & \text{for } d \equiv 1 \text{ or } 2 \pmod{4} \\ \frac{1}{2}\left(1 + i\sqrt{d}\right) & \text{for } d \equiv 3 \pmod{4}. \end{cases} \tag{28}$$

Then the NOME is

$$q \equiv e^{i\pi r} = \begin{cases} e^{2\pi i\left(i\sqrt{d}\right)} & \text{for } d \equiv 1 \text{ or } 2 \pmod{4} \\ e^{2\pi i\left(1+i\sqrt{d}\right)/2} & \text{for } d \equiv 3 \pmod{4} \end{cases}$$

$$= \begin{cases} e^{-2\pi\sqrt{d}} & \text{for } d \equiv 1 \text{ or } 2 \pmod{4} \\ -e^{-\pi\sqrt{d}} & \text{for } d \equiv 3 \pmod{4}. \end{cases} \tag{29}$$

It then turns out that $j(q)$ is an ALGEBRAIC INTEGER of degree $h(-d)$, where $h(-d)$ is the CLASS NUMBER of the DISCRIMINANT $-d$ of the QUADRATIC FIELD $\mathbb{Q}(\sqrt{n})$ (Silverman 1986). The first term in the LAURENT

SERIES is then $q^{-1}=e^{-2\pi\sqrt{n}}$ or $-e^{-\pi\sqrt{n}}$, and all the later terms are POWERS of q^{-1}, which are small numbers. The larger n, the faster the series converges. If $h(-d)=1$, then $j(q)$ is a ALGEBRAIC INTEGER of degree 1, i.e., just a plain INTEGER. Furthermore, the INTEGER is a perfect CUBE.

The numbers whose LAURENT SERIES give INTEGERS are those with CLASS NUMBER 1. But these are precisely the HEEGNER NUMBERS -1, -2, -3, -7, -11, -19, -43, -67, -163. The greater (in ABSOLUTE VALUE) the HEEGNER NUMBER d, the closer to an INTEGER is the expression $e^{\pi\sqrt{-n}}$, since the initial term in $j(q)$ is the largest and subsequent terms are the smallest. The best approximations with $h(-d)=1$ are therefore

$$e^{\pi\sqrt{43}}\approx 960^3+744-2.2\times 10^{-4} \tag{30}$$

$$e^{\pi\sqrt{67}}\approx 5280^3+744-1.3\times 10^{-6} \tag{31}$$

$$e^{\pi\sqrt{163}}\approx 640320^3+744-7.5\times 10^{-13}. \tag{32}$$

The exact values of $j(q)$ corresponding to the HEEGNER NUMBERS are

$$j(-e^{-\pi})=12^3 \tag{33}$$

$$j\left(e^{-2\pi\sqrt{2}}\right)=20^3 \tag{34}$$

$$j\left(-e^{-\pi\sqrt{3}}\right)=0^3 \tag{35}$$

$$j\left(-e^{-\pi\sqrt{7}}\right)=-15^3 \tag{36}$$

$$j\left(-e^{-\pi\sqrt{11}}\right)=-32^3 \tag{37}$$

$$j\left(-e^{-\pi\sqrt{19}}\right)=-96^3 \tag{38}$$

$$j\left(-e^{-\pi\sqrt{43}}\right)=-960^3 \tag{39}$$

$$j\left(-e^{-\pi\sqrt{67}}\right)=-5280^3 \tag{40}$$

$$j\left(-e^{-\pi\sqrt{163}}\right)=-640320^3. \tag{41}$$

(The number 5280 is particularly interesting since it is also the number of feet in a mile.) The ALMOST INTEGER generated by the last of these, $e^{\pi\sqrt{163}}$ (corresponding to the field $\mathbb{Q}(\sqrt{-163})$ and the IMAGINARY QUADRATIC FIELD of maximal discriminant), is sometimes known as the RAMANUJAN CONSTANT. However, this attribution is historically fallacious since this amazing property of $e^{\pi\sqrt{163}}$ was first noted by Hermite (1859) and does not seem to appear in any of the works of Ramanujan.

$e^{\pi\sqrt{22}}$, $e^{\pi\sqrt{37}}$, and $e^{\pi\sqrt{58}}$ are also ALMOST INTEGERS. These correspond to binary quadratic forms with discriminants -88, -148, and -232, all of which have CLASS NUMBER two and were noted by Ramanujan (Berndt 1994).

It turns out that the j-function also is important in the CLASSIFICATION THEOREM for finite simple groups, and that the factors of the orders of the SPORADIC GROUPS, including the celebrated MONSTER GROUP, are also related.

Jinc Function

The jinc function is defined as

$$\operatorname{jinc}(x) \equiv \frac{J_1(x)}{x},$$

where $J_1(x)$ is a BESSEL FUNCTION OF THE FIRST KIND, and satisfies $\lim_{x\to 0} \operatorname{jinc}(x) = 1/2$. The DERIVATIVE of the jinc function is given by

$$\operatorname{jinc}'(x) = -\frac{J_2(x)}{x}.$$

The function is sometimes normalized by multiplying by a factor of 2 so that $\operatorname{jinc}(0) = 1$ (Siegman 1986, p. 729).

j-Invariant

An invariant of an ELLIPTIC CURVE given in the form

$$y^2 = x^3 + ax + b$$

which is closely related to the DISCRIMINANT and defined by

$$j(E) \equiv \frac{2^8 3^3 a^3}{4a^3 + 27b^2}.$$

The determination of j as an ALGEBRAIC INTEGER in the QUADRATIC FIELD $\mathbb{Q}(j)$ is discussed by Greenhill (1891), Weber (1902), Berwick (1928), Watson (1938), Gross and Zaiger (1985), and Dorman (1988). The norm of j in $\mathbb{Q}(j)$ is the CUBE of an INTEGER in $\mathbb{Z}$.

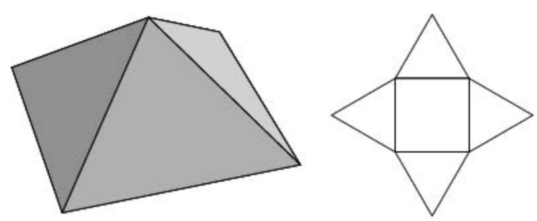
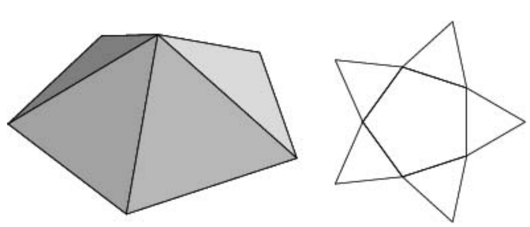
Johnson Solid



The Johnson solids are the CONVEX POLYHEDRA having regular faces and equal edge lengths (with the exception of the completely regular PLATONIC SOLIDS, the "SEMIREGULAR" ARCHIMEDEAN SOLIDS, and the two infinite families of PRISMS and ANTIPRISMS). There are 28 simple (i.e., cannot be dissected

into two other regular-faced polyhedra by a plane) regular-faced polyhedra in addition to the PRISMS and ANTIPRISMS (Zalgaller 1969), and Johnson (1966) proposed and Zalgaller (1969) proved that there exist exactly 92 Johnson solids in all.



There is a near-Johnson solid which can be constructed by inscribing regular nonagons inside the eight triangular faces of a regular octahedron, then joining the free edges to the 24 triangles and finally the remaining edges of the triangles to six squares, with one square for each octahedral vertex. It turns out that the triangles are not quite equilateral, making the edges that bound the squares a slightly different length from that of the enneagonal edge. However, because the differences in edge lengths are so small, the flexing of an average model allows the solid to be constructed with all edges equal (Olshevsky).

A database of solids and VERTEX NETS of these solids is maintained on the Bell Laboratories Netlib server, but a few errors exist in several entries. A concatenated and corrected version of the files is given by Weisstein, together with *Mathematica* code to display the solids and nets. The following table summarizes the names of the Johnson solids and gives their images and nets.

Joint Distribution Function

A joint distribution function is a DISTRIBUTION FUNCTION $D(x,y)$ in two variables defined by

$$D(x,y) \equiv P(X \leq x, Y \leq y) \quad (1)$$

$$D_x(x) \equiv \lim_{y \to \infty} D(x,y) \quad (2)$$

$$D_y(y) \equiv \lim_{x \to \infty} D(x,y) \quad (3)$$

so that the joint probability function satisfies

$$D[(x,y) \in C] = \iint_{(X,Y) \in C} P(X,Y)\,dX\,dY \quad (4)$$

$$D(x \in A, y \in B) = \int_{Y \in B} \int_{X \in A} P(X,Y)\,dX\,dY \quad (5)$$

$$D(x,y) = P\{X \in (-\infty, x], Y \in (-\infty, y]\}$$

$$= \int_{-\infty}^{z} \int_{-\infty}^{y} P(X,Y)\,dX\,dY \quad (6)$$

$$D(a \leq x \leq a + da, b \leq y \leq b + db)$$

$$= \int_{b}^{b+db} \int_{a}^{a+da} P(X,Y)\,dX\,dY \approx P(a,b)\,da\,db. \quad (7)$$

Two random variables X and Y are independent IFF

$$D(x,y) = D_x(x) D_y(y) \quad (8)$$

for all x and y and

$$P(x,y) = \frac{\partial^2 D(x,y)}{\partial x \partial y}. \quad (9)$$

A multiple distribution function is OF THE FORM

$$D(x_1, \ldots, x_n) \equiv P(X_1 \leq x_1, \ldots, X_n \leq x_n). \quad (10)$$

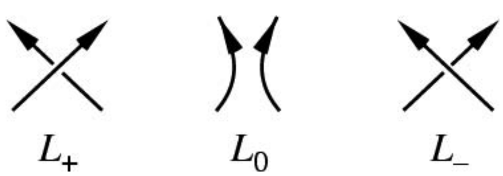
Jones Polynomial

The second KNOT POLYNOMIAL discovered. Unlike the first-discovered ALEXANDER POLYNOMIAL, the Jones polynomial can sometimes distinguish handedness (as can its more powerful generalization, the HOMFLY POLYNOMIAL). Jones polynomials are LAURENT POLYNOMIALS in t assigned to an $\mathbb{R}^3$ KNOT. The Jones polynomials are denoted $V_L(t)$ for LINKS, $V_K(t)$ for KNOTS, and normalized so that



$$V_{\text{unknot}}(t) = 1. \tag{1}$$

For example, the Jones polynomial of the TREFOIL KNOT is given by

$$V_{\text{trefoil}}(t) = t + t^3 - t^4. \tag{2}$$

If a LINK has an ODD number of components, then V_L is a LAURENT POLYNOMIAL over the INTEGERS; if the number of components is EVEN, $V_L(t)$ is $t^{1/2}$ times a LAURENT POLYNOMIAL. The Jones polynomial of a KNOT SUM $L_1 \# L_2$ satisfies

$$V_{L_1 \# L_2} = \left(V_{L_1}\right)\left(V_{L_2}\right). \tag{3}$$

The SKEIN RELATIONSHIP for under- and overcrossings is

$$t^{-1} V_{L_+} - t V_{L_-} = \left(t^{1/2} - t^{-1/2}\right) V_{L_0}. \tag{4}$$

Combined with the link sum relationship, this allows Jones polynomials to be built up from simple knots and links to more complicated ones.

Some interesting identities from Jones (1985) follow. For any LINK L,

$$V_L(-1) = \Delta_L(-1), \tag{5}$$

where Δ_L is the ALEXANDER POLYNOMIAL, and

$$V_L(1) = (-2)^{p-1}, \tag{6}$$

where p is the number of components of L. For any KNOT K,

$$V_K\left(e^{2\pi i/3}\right) = 1 \tag{7}$$

and

$$\frac{d}{dt} V_K(1) = 0 \tag{8}$$

Let K^* denote the MIRROR IMAGE of a KNOT K. Then

$$V_{K^*}(t) = V_K\left(t^{-1}\right). \tag{9}$$

For example, the right-hand and left-hand TREFOIL KNOTS have polynomials

$$V_{\text{trefoil}}(t) = t + t^3 - t^4 \tag{10}$$

$$V_{\text{trefoil}^*}(t) = t^{-1} + t^{-3} - t^{-4}. \tag{11}$$

Jones defined a simplified trace invariant for knots by

$$W_K(t) = \frac{1 - V_K(t)}{(1 - t^3)(1 - t)}. \tag{12}$$

The ARF INVARIANT of W_K is given by

$$\text{Arf}(K) = W_K(i) \tag{13}$$

(Jones 1985), where I is $\sqrt{-1}$. A table of the W polynomials is given by Jones (1985) for knots of up to eight crossings, and by Jones (1987) for knots of up to 10 crossings. (Note that in these papers, an additional polynomial which Jones calls V is also tabulated, but it is not the conventionally defined Jones polynomial.)

Jones polynomials were subsequently generalized to the two-variable HOMFLY POLYNOMIALS, the relationship being

$$V(t) = P\left(a = t, x = t^{1/2} - t^{-1/2}\right) \tag{14}$$

$$V(t) = P\left(\ell = it, m = i\left(t^{-1/2} - t^{1/2}\right)\right). \tag{15}$$

They are related to the KAUFFMAN POLYNOMIAL F by

$$V(t) = F\left(-t^{-3/4}, t^{-1/4} + t^{1/4}\right). \tag{16}$$

Jones (1987) gives a table of BRAID WORDS and W polynomials for knots up to 10 crossings. Jones polynomials for KNOTS up to nine crossings are given in Adams (1994) and for oriented links up to nine crossings by Doll and Hoste (1991). All PRIME KNOTS with 10 or fewer crossings have distinct Jones polynomials. It is not known if there is a nontrivial knot with Jones polynomial 1. The Jones polynomial of an (m, n)-TORUS KNOT is

$$\frac{t(m-1)(n-1)/2(1 - t^{m+1} - t^{n+1} + t^{m+n})}{1 - t^2} \tag{17}$$

Let k be one component of an oriented LINK L. Now form a new oriented LINK L^* by reversing the orientation of k. Then

$$V_{L^*} = t^{-3\lambda} V(L), \tag{18}$$

where V is the Jones polynomial and λ is the LINKING NUMBER of k and $L - k$. No such result is known for HOMFLY POLYNOMIALS (Lickorish and Millett 1988).

Birman and Lin (1993) showed that substituting the POWER SERIES for e^x as the variable in the Jones polynomial yields a POWER SERIES whose COEFFICIENTS are VASSILIEV INVARIANTS.

Let L be an oriented connected LINK projection of n crossings, then

$$n \geq \text{span}\, V(L), \tag{19}$$

with equality if L is ALTERNATING and has no REMOVABLE CROSSING (Lickorish and Millett 1988).

There exist distinct KNOTS with the same Jones polynomial. Examples include (05-01, 10-32), (08-08, 10-29), (08-16, 10-56), (10-25, 10-56), (10-22, 10-35), (10-41, 10-94), (10-43, 10-91), (10-59, 10-06), (10-60, 10-83), (10-71, 10-04), (10-73, 10-86), (10-81, 10-09), and (10-37, 10-55) (Jones 1987). Incidentally, the first four of these also have the same HOMFLY POLYNOMIAL.

Witten (1989) gave a heuristic definition in terms of a topological quantum field theory, and Sawin (1996) showed that the "quantum group" $U_q(sl_2)$ gives rise to the Jones polynomial.

Jonquière's Function

POLYGAMMA FUNCTION

Jordan Algebra

A NONASSOCIATIVE ALGEBRA named after physicist Pascual Jordan which satisfies

$$xy = yx \tag{1}$$

and

$$(xx)(xy) = x((xx)y)). \tag{2}$$

The latter is equivalent to the so-called JORDAN IDENTITY

$$(xy)x^2 = x(yx^2) \tag{3}$$

(Schafer 1996, p. 4). An ASSOCIATIVE ALGEBRA A with associative product xy can be made into a Jordan algebra A^+ by the JORDAN PRODUCT

$$x \cdot y = \tfrac{1}{2}(xy + yx). \tag{4}$$

Division by 2 gives the nice identity $x \cdot x = xx$, but it must be omitted in characteristic $p = 2$.

Unlike the case of a LIE ALGEBRA, not every Jordan algebra is isomorphic to a SUBALGEBRA of some A^+. Jordan algebras which are isomorphic to a subalgebra are called SPECIAL JORDAN ALGEBRAS, while those that are not are called EXCEPTIONAL JORDAN ALGEBRAS.

See also ANTICOMMUTATOR, NONASSOCIATIVE ALGEBRA

Jordan Basis

Given a matrix A, a Jordan basis satisfies

$$\mathsf{A}b_{i,1} = \lambda_i b_{i,1}$$

and

$$\mathsf{A}b_{i,j} = \lambda_i b_{i,j} + b_{i,j-1},$$

and provides the means by which any COMPLEX MATRIX A can be written in JORDAN CANONICAL FORM.

See also JORDAN BLOCK, JORDAN CANONICAL FORM

Jordan Block

A matrix, also called a canonical box matrix, having zeros everywhere except along the DIAGONAL and SUPERDIAGONAL, with each element of the DIAGONAL consisting of a single number λ, and each element of the SUPERDIAGONAL consisting of a 1. For example,

$$\begin{bmatrix} \lambda & 1 & 0 & \cdots & 0 & 0 \\ 0 & \lambda & 1 & \ddots & 0 & 0 \\ 0 & 0 & \lambda & \ddots & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & 1 \\ 0 & 0 & 0 & \cdots & 0 & \lambda \end{bmatrix}$$

(Ayres 1962, p. 206). A JORDAN CANONICAL FORM consists of one or more Jordan blocks.

The convention that 1s be along the SUBDIAGONAL instead of the SUPERDIAGONAL is sometimes adopted instead (Faddeeva 1958, p. 50).

See also DIAGONAL MATRIX, JORDAN CANONICAL FORM, SUBDIAGONAL

References

Ayres, F. Jr. *Theory and Problems of Matrices.* New York: Schaum, p. 206, 1962.

Golub, G. H. and van Loan, C. F. *Matrix Computations, 3rd ed.* Baltimore, MD: Johns Hopkins University Press, p. 317, 1996.

Jordan Canonical Form

A BLOCK MATRIX in which the blocks consist of CANONICAL BOX MATRICES with possibly differing constants λ_i, also called classical canonical form. For example,

$$\begin{bmatrix} \lambda_1 & 1 & 0 & \cdots & 0 & & & & & & \\ 0 & \lambda_1 & 1 & \ddots & 0 & & & & & & \\ 0 & 0 & \lambda_1 & \ddots & 0 & & & & & & \\ \vdots & \ddots & \ddots & \ddots & 1 & & & & & & \\ 0 & 0 & 0 & \cdots & \lambda_1 & & & & & & \\ & & & & & \ddots & & & & & \\ & & & & & & \lambda_k & 1 & 0 & \cdots & 0 \\ & & & & & & 0 & \lambda_k & 1 & \ddots & 0 \\ & & & & & & 0 & 0 & \lambda_k & \ddots & 0 \\ & & & & & & \vdots & \ddots & \ddots & \ddots & 1 \\ & & & & & & 0 & 0 & 0 & \cdots & \lambda_k \end{bmatrix}$$

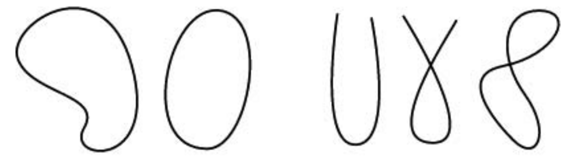
(Ayres 1962, p. 206). A specific example is given by

$$\begin{bmatrix} 5 & 1 & 0 & 0 & 0 & 0 \\ 0 & 5 & 0 & 0 & 0 & 0 \\ 0 & 0 & 5 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1-2i & 1 & 0 \\ 0 & 0 & 0 & 0 & 1-2i & 1 \\ 0 & 0 & 0 & 0 & 0 & 1-2i \end{bmatrix},$$

which has three JORDAN BLOCKS.

Any COMPLEX MATRIX A can be written in Jordan canonical form by finding a JORDAN BASIS b_{ij} for each JORDAN BLOCK. In fact, any matrix with coefficients in an algebraically closed FIELD can be put into Jordan canonical form. The dimensions of the blocks corresponding to the EIGENVALUE λ can be recovered by the sequence

$$a_i = \dim \text{Null}(\mathsf{A} - \lambda)^i.$$



The convention that the submatrices have 1s on the SUBDIAGONAL instead of the SUPERDIAGONAL is also used sometimes (Faddeeva 1958, p. 50).

Jordan Curve

Jordan curves *non-Jordan curves*

A Jordan curve is a plane curve which is topologically equivalent to (a HOMEOMORPHIC image of) the UNIT CIRCLE, i.e., it is SIMPLE and CLOSED.
It is not known if every Jordan curve contains all four VERTICES of some SQUARE, but it has been proven true for "sufficiently smooth" curves and closed convex curves (Schnirelman 1944; Steinhaus 1990, p. 104). For every TRIANGLE T and Jordan curve J, J has an INSCRIBED TRIANGLE similar to T.

Jordan Matrix Decomposition

The Jordan matrix decomposition is the decomposition of a square matrix M into the form

$$\mathsf{M} = \mathsf{SJS}^{-1}, \tag{1}$$

where M and J are SIMILAR MATRICES, J is a matrix of JORDAN CANONICAL FORM, and S^{-1} is the MATRIX INVERSE of S. In other words, M is a SIMILARITY TRANSFORMATION of a matrix J in JORDAN CANONICAL FORM. The proof that any square matrix can be brought into JORDAN CANONICAL FORM is rather complicated (Turnbull and Aitken 1932; Faddeeva 1958, p. 49; Halmos 1958, p. 112).

Jordan decomposition is also associated with the MATRIX EQUATION $\mathsf{AX} = \mathsf{XB}$ and the special case $\mathsf{A} = \mathsf{B}$.

The Jordan matrix decomposition is implemented in *Mathematica* as `JordanDecomposition[m]`, and returns a list $\{s, j\}$. Note that *Mathematica* takes the CANONICAL BOX MATRICES in the JORDAN CANONICAL FORM to have 1s along the SUPERDIAGONAL instead of the SUBDIAGONAL. For example, a Jordan decomposition of

$$\mathsf{M} = \begin{bmatrix} 2 & 4 & -6 & 0 \\ 4 & 6 & -3 & -4 \\ 0 & 0 & 4 & 0 \\ 0 & 4 & -6 & 2 \end{bmatrix} \tag{2}$$

is given by

$$\mathsf{S} = \begin{bmatrix} 1 & -\frac{1}{4} & 0 & 1 \\ 0 & \frac{1}{4} & 3 & 1 \\ 0 & 0 & 2 & 0 \\ 1 & 0 & 0 & 1 \end{bmatrix} \tag{3}$$

$$\mathsf{J} = \begin{bmatrix} 2 & 1 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 6 \end{bmatrix}, \tag{4}$$

Jordan Measure

Let the set M correspond to a bounded, NONNEGATIVE function f on an interval $0 \leq f(x) \leq c$ for $x \in [a, b]$. The Jordan measure, when it exists, is the common value of the outer and inner Jordan measures of M.

The outer Jordan measure is the greatest lower bound of the areas of the covering of M, consisting of finite unions of RECTANGLES. The inner Jordan measure of M is the difference between the AREA $c(a-b)$ of the RECTANGLE S with base $[a, b]$ and height c, and the outer measure of the complement of M in S.

Jordan Measure Decomposition

If μ is a REAL MEASURE (i.e., a MEASURE that takes on real values), then one can decompose it according to where it is positive and negative. The positive variation is defined by

$$\mu^+ = \tfrac{1}{2}(|\mu| + \mu), \tag{1}$$

where $|\mu|$ is the TOTAL VARIATION MEASURE. Similarly, the negative variation is

$$\mu^- = \tfrac{1}{2}(|\mu| - \mu). \tag{2}$$

Then the Jordan decomposition of μ is defined as

$$\mu = \mu^+ - \mu^-. \tag{3}$$

When μ already is a positive measure then $\mu = \mu^+$.

More generally, if μ is ABSOLUTELY CONTINUOUS, i.e.,

$$\mu(E) = \int_E f dx, \tag{4}$$

then so are μ^+ and μ^-. The positive and negative variations can also be written as

$$\mu^+(E) = \int_E f^+ dx \tag{5}$$

and

$$\mu^-(E) = \int_E f^- dx, \tag{6}$$

where $f = f^+ - f^-$ is the decomposition of f into its positive and negative parts.

The Jordan decomposition has a so-called minimum property. In particular, given any positive measure λ, the measure μ has another decomposition

$$\mu = (\mu^+ + \lambda) - (\mu^- + \lambda). \tag{7}$$

The Jordan decomposition is minimal with respect to these changes. One way to say this is that any decomposition $\mu = \lambda_1 - \lambda_2$ must have $\lambda_1 \geq \mu^+$ and $\lambda_2 \geq \mu^-$.

Jordan's Inequality

For $0 \leq x \leq \pi/2$

$$\frac{2}{\pi} x \leq \sin x \leq x.$$

References

Yuefeng, F. "Jordan's Inequality." *Math. Mag.* **69**, 126, 1996.

Jordan's Lemma

Jordan's lemma shows the value of the INTEGRAL

$$I \equiv \int_{-\infty}^{\infty} f(x) e^{iax} dx \tag{1}$$

along the REAL AXIS is 0 for "nice" functions which satisfy $\lim_{R\to\infty} |f(Re^{i\theta})| = 0$. This is established using a CONTOUR INTEGRAL I_R which satisfies

$$\lim_{R\to\infty} |I_R| \leq \frac{\pi}{a} \lim_{R\to\infty} \epsilon = 0. \tag{2}$$

To derive the lemma, write

$$x \equiv Re^{i\theta} = R(\cos\theta + i\sin\theta) \tag{3}$$

$$dx = iRe^{i\theta} d\theta \tag{4}$$

and define the CONTOUR INTEGRAL

$$I_R = \int_0^\pi f(Re^{i\theta}) e^{iaR\cos\theta - aR\sin\theta} iRe^{i\theta} d\theta \tag{5}$$

Then

$$|I_R| = R\int_0^\pi |f(Re^{i\theta})| |e^{iaR\cos\theta}| |e^{-aR\sin\theta}| |i| |e^{i\theta}| d\theta$$

$$= R\int_0^\pi |f(Re^{i\theta})| e^{-aR\sin\theta} d\theta.$$

$$= 2R\int_0^{\pi/2} |f(Re^{i\theta})| e^{-aR\sin\theta} d\theta. \tag{6}$$

Now, if $\lim_{R\to\infty} |f(Re^{i\theta})| = 0$, choose an ϵ such that $|f(Re^{i\theta})| \leq \epsilon$, so

$$|I_R| \leq 2R\epsilon \int_0^{\pi/2} e^{-aR\sin\theta} d\theta. \tag{7}$$

But, for $\theta \in [0, \pi/2]$,

$$\frac{2}{\pi}\theta \leq \sin\theta, \tag{8}$$

so

$$|I_R| \leq 2R\epsilon \int_0^{\pi/2} e^{-2aR\theta/\pi} d\theta$$

$$= 2\epsilon R \frac{1 - e^{-aR}}{\frac{2aR}{\pi}} = \frac{\pi\epsilon}{a}\left(1 - e^{-aR}\right). \quad (9)$$

As long as $\lim_{R\to\infty} |f(z)| = 0$, Jordan's lemma

$$\lim_{R\to\infty} |I_R| \leq \frac{\pi}{a} \lim_{R\to\infty} \epsilon = 0 \quad (10)$$

then follows.

Jordan-Hölder Theorem

The composition QUOTIENT GROUPS belonging to two COMPOSITION SERIES of a FINITE GROUP G are, apart from their sequence, ISOMORPHIC in pairs. In other words, if

$$I \subset H_s \subset \ldots \subset H_2 \subset H_1 \subset G$$

is one COMPOSITION SERIES and

$$I \subset K_t \subset \ldots \subset K_2 \subset K_1 \subset G$$

is another, then $t = s$, and corresponding to any composition quotient group K_j/K_{j+1}, there is a composition QUOTIENT GROUP H_i/H_{i+1} such that

$$\frac{K_j}{K_{j+1}} \cong \frac{H_i}{H_{i+1}}.$$

This theorem was proven in 1869–889.

Josephus Problem

Given a group of n men arranged in a CIRCLE under the edict that every mth man will be executed going around the CIRCLE until only one remains, find the position $L(n, m)$ in which you should stand in order to be the last survivor (Ball and Coxeter 1987). The list giving the place in the execution sequence of the first, second, etc. man can be given by `Josephus[m, n]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``). To obtain the ordered list of men who are consecutively slaughtered, `InversePermutation` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``) can be applied to the output of `Josephus`.

The following array gives the original position of the last survivor out of a group of $n = 1, 2, \ldots$, if every mth man is killed:

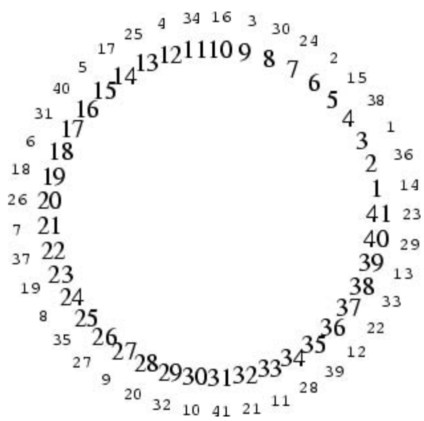
1									
2	1								
3	3	2							
4	1	1	2						
5	3	4	1	2					
6	5	1	5	1	4				
7	7	4	2	6	3	5			
8	1	7	6	3	1	4	4		
9	3	1	1	8	7	2	3	8	
10	5	4	5	3	3	9	1	7	8

(Sloane's A032434). The survivor for $m = 2$ can be given analytically by

$$L(n, 2) = 1 + 2n - 2^{1 + \lfloor \lg n \rfloor},$$

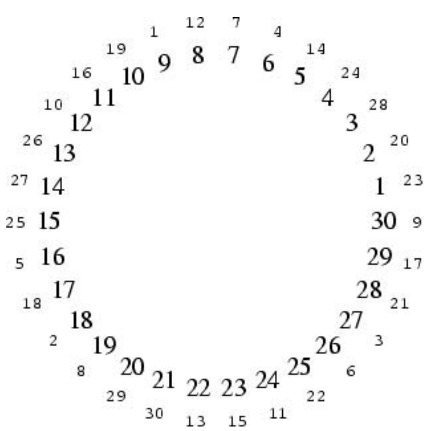
where $\lfloor n \rfloor$ is the FLOOR FUNCTION and LG is the LOGARITHM to base 2. The first few solutions are therefore 1, 1, 3, 1, 3, 5, 7, 1, 3, 5, 7, 9, 11, 13, 15, 1, ... (Sloane's A006257).

The original position of the second-to-last survivor is given in the following table for $n = 2, 3, \ldots$:>



1	1								
2	1	1							
3	1	1	2						
4	3	2	1	2					
5	1	1	5	1	4				
6	3	1	2	1	3	4			
7	1	4	6	3	1	3	4		
8	3	1	1	2	7	1	3	7	
9	5	4	5	3	3	8	1	6	4

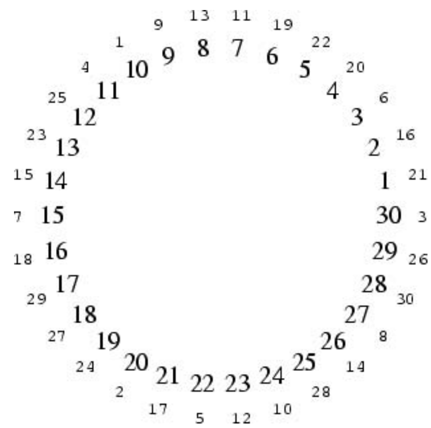
(Sloane's A032435).



The original position of the second-to-last survivor is given in the following table for $n = 2, 3, \ldots$:>

1	1	1							
2	1	1	1						
3	1	2	1	2					
4	1	1	3	1	2				
5	3	1	2	1	1	2			
6	1	4	3	3	1	1	2		
7	3	1	1	2	4	1	1	2	
8	1	4	1	3	3	5	1	1	4

(Sloane's A032436).



The original Josephus problem consisted of a CIRCLE of 41 men with every third man killed ($n = 41$, $m = 3$). In order for the lives of the last two men to be spared, they must be placed at positions 31 (last) and 16 (second-to-last). The complete list in order of execution is 3, 6, 9, 12, 15, 18, 21, 24, 27, 30, 33, 36, 39, 1, 5, 10, 14, 19, 23, 28, 32, 37, 41, 7, 13, 20, 26, 34, 40, 8, 17, 29, 38, 11, 25, 2, 22, 4, 35, 16, 31.

Another version of the problem considers a CIRCLE of two groups (say, "A" and "B") of 15 men each (giving a total of 30 men), with every ninth man cast overboard. To save all the members of the "A" group, the men must be placed at positions 1, 2, 3, 4, 10, 11, 13, 14, 15, 17, 20, 21, 25, 28, 29. Written out explicitly, the order is

AAAABBBBBAABAAABABBAABBBABBAAB.

This sequence of letters can be remembered with the aid of the MNEMONIC "From numbers' aid and art, never will fame depart." Consider the vowels only, assign $a = 1$, $e = 2$, $i = 3$, $o = 4$, $u = 5$, and alternately add a number of letters corresponding to a vowel value, so 4A (o), 5B (u), 2A (e), etc. (Mott-Smith 1954, §149, pp. 94 and 209–10; Ball and Coxeter 1987).

If instead every *tenth* man is thrown overboard, the men from the "A" group must be placed in positions 1, 2, 4, 5, 6, 12, 13, 16, 17, 18, 19, 21, 25, 28, 29. Written out explicitly,

AABAAABBBBBAABBAAAABABBBABBAAB

which can be constructed using the Latin MNEMONIC "Rex paphi cum gente bona dat signa serena" (Ball and Coxeter 1987).

Mott-Smith (1954, §153, pp. 96 and 212) discusses a card game called "Out and Under" in which cards at the top of a deck are alternately discarded and placed at the bottom. This is a Josephus problem with parameter $m = 2$, and Mott-Smith hints at the above closed-form solution.

Joyce Sequence

The sequence of numbers giving the number of digits in n^{n^n}. The sequence n^{n^n} for $n = 1, 2, ...$ is 1, 16, 7625597484987, ... (Sloane's A002488; Rossier 1948), so the Joyce sequence is 1, 2, 13, 155, 2185, 36306, ... (Sloane's A054382). Laisant (1906) found the term $j(9)$, and Uhler (1947) published the logarithm of this number to 250 decimal places (Wells 1986, p. 208).

The sequence is named in honor of the following excerpt from the "Ithaca" chapter of James Joyce's *Ulysses*: "Because some years previously in 1886 when occupied with the problem of the quadrature of the circle he had learned of the existence of a number computed to a relative degree of accuracy to be of such magnitude and of so many places, e.g., the 9th power of the 9th power of 9, that, the result having been obtained, 33 closely printed volumes of 1000 pages each of innumerable quires and reams of India paper would have to be requisitioned in order to contain the complete tale of its printed integers of units, tens, hundreds, thousands, tens of thousands, hundreds of thousands, millions, tens of millions, hundreds of millions, billions, the nucleus of the nebula of every digit of every series containing succinctly the potentiality of being raised to the utmost kinetic elaboration of any power of any of its powers."

Jug

THREE JUG PROBLEM

Jugendtraum

The German mathematician Kronecker proved that all the Galois extensions of the RATIONALS Q with ABELIAN Galois groups are SUBFIELDS of cyclotomic fields $Q(\mu_n)$, where μ_n is the group of nth ROOTS OF UNITY. He then sought to find a similar function whose division values would generate the Abelian extensions of an arbitrary NUMBER FIELD. He discovered that the j-FUNCTION works for IMAGINARY QUADRATIC FIELDS K, but the completion of this problem, known as Kronecker's Jugendtraum ("dream of youth"), for more general FIELDS remains one of the great unsolved problems in NUMBER THEORY.

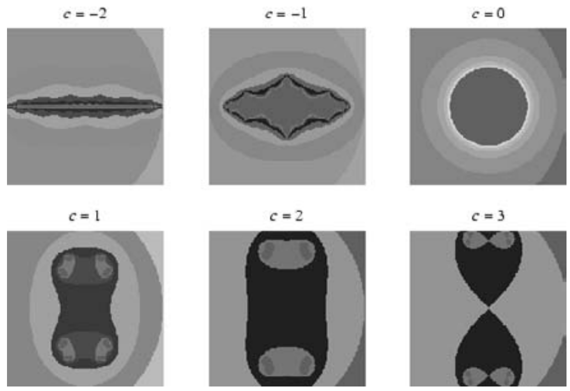
Julia Fractal

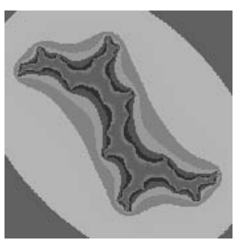


JULIA SET

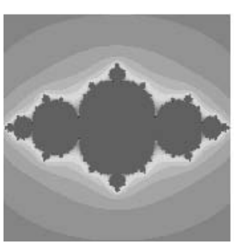
Julia Set

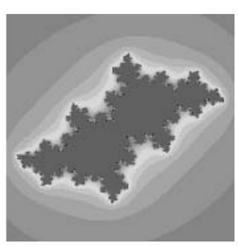
Let $R(z)$ be a RATIONAL FUNCTION

$$R(z) \equiv \frac{P(z)}{Q(z)}, \qquad (1)$$



where $z \in \mathbb{C}^*$, $z \in \mathbb{C}^*$ is the RIEMANN SPHERE $\mathbb{C} \cup \{\infty\}$, and P and Q are POLYNOMIALS without common divisors. The "filled-in" Julia set J_R is the set of points z which do not approach infinity after $R(z)$ is repeatedly applied (corresponding to a STRANGE ATTRACTOR). The true Julia set J is the boundary of the filled-in set (the set of "exceptional points"). There are two types of Julia sets: connected sets (FATOU SET) and CANTOR SETS (FATOU DUST).





Quadratic Julia sets are generated by the quadratic mapping

$$z_{n+1} = z_n^2 + c \tag{2}$$

for fixed c. For almost every c, this transformation generates a FRACTAL. Examples are shown above for various values of c. The resulting object is *not* a fractal for $c = -2$ (Dufner *et al.* 1998, pp. 224–26) and $c = 0$ (Dufner *et al.* 1998, pp. 125–26), although it does not seem to be known if these two are the *only* such exceptional values.

The special case of c on the boundary of the MANDELBROT SET is called a DENDRITE FRACTAL (top left figure, computed using $c = i$), $c = -0.123 + 0.745i$ is called DOUADY'S RABBIT FRACTAL (left figure), $c = -0.75$ is called the SAN MARCO FRACTAL (middle figure), and $c = -0.391 - 0.587i$ is the SIEGEL DISK FRACTAL (right figure). Julia sets can be rendered in *Mathematica* using the following code.

```
JuliaSet[n_:50,c_,rmax_:3.,{{x1_,x2_},{y1_,-
y2_}},opts___]:=
   DensityPlot[-Length[
      FixedPointList[#^2+c&,x+I  y,n,SameTest-
>(Abs[#2]>rmax&)]],
         {x,x1,x2},{y,y1,y2},opts,PlotPoints-
>200,Mesh->False,
    Frame->False,AspectRatio->Automatic
   ]
```

The equation for the quadratic Julia set is a CONFORMAL MAPPING, so angles are preserved. Let J be the JULIA SET, then $x' \mapsto x$ leaves J invariant. If a point P is on J, then all its iterations are on J. The transformation has a two-valued inverse. If $b = 0$ and y is started at 0, then the map is equivalent to the LOGISTIC MAP. The set of all points for which J is connected is known as the MANDELBROT SET.

For a Julia set J_c with $c \ll 1$, the CAPACITY DIMENSION is

$$d_{\text{capacity}} = 1 + \frac{|c|^2}{4 \ln 2} + \mathcal{O}(|c|^3). \tag{3}$$

For small c, J_c is also a JORDAN CURVE, although its points are not COMPUTABLE.

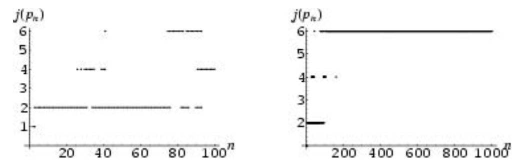
Jump

A point of DISCONTINUITY, also called a LEAP.

See also DISCONTINUITY, JUMP ANGLE, JUMPING CHAMPION

References

Jeffreys, H. and Jeffreys, B. S. "Leap at a Discontinuity." §1.094 in *Methods of Mathematical Physics, 3rd ed.*



Cambridge, England: Cambridge University Press, p. 26, 1988.

Jump Angle

A GEODESIC TRIANGLE with oriented boundary yields a curve which is piecewise DIFFERENTIABLE. Furthermore, the TANGENT VECTOR varies continuously at all but the three corner points, where it changes suddenly. The angular difference of the tangent vectors at these corner points are called the jump angles.

See also ANGULAR DEFECT, GAUSS-BONNET FORMULA

Jumping Champion

An integer $j(n)$ is called a JUMPING CHAMPION if $j(n)$ is the most frequently occurring difference between consecutive PRIMES $\leq n$ (Odlyzko *et al.*). This term was coined by J. H. Conway in 1993. There are occasionally several jumping champions in a range. The scatter plots above show the jumping champions for small n, and the ranges of number having given jumping champion sets are summarized in the following table.

$j(n)$	n
1	3
1, 2	5
2	7–00, 103–06, 109–12, ...
2, 4	101–02, 107–08, 113–30, ...
4	131–38, ...
2, 4, 6	179–80, 467–90, ...
2, 6	379–88, 421–32, ...
6	389–20, ...

Odlyzko *et al.* give a table of jumping champions for $n \leq 1000$, consisting mainly of 2, 4, and 6. 6 is the jumping champion up to about $n \approx 1.74 \times 10^{35}$, at which point 30 dominates. At $n \approx 10^{425}$, 210 becomes champion, and subsequent PRIMORIALS are conjectured to take over at larger and larger n. Erdos and Straus (1980) proved that the jumping champions tend to infinity under the assumption of a quantitative form of the k-tuples conjecture.

Wolf gives a table of approximate values $\tilde{n}$ at which the PRIMORIAL (p_n) will become a champion. An estimate for $\tilde{n}$ is given by

$$\tilde{n} = n^{n+o(n)}.$$

Jung's Theorem

Every finite set of points with SPAN d has an enclosing CIRCLE with RADIUS no greater than $\sqrt{3}d/3$.

In 3-D, a generalization of the theorem states that every set of points with SPAN d has an enclosing SPHERE with RADIUS no greater than $\sqrt{6}d/4$ (Smarandache 1992, 1996).

Just If

IFF

Just One

EXACTLY ONE

Just Rigid

A FRAMEWORK is called "just rigid" if it is RIGID, but ceases to be so when any single bar is removed. Lamb (1928, pp. 93–4) proved that a NECESSARY (but not SUFFICIENT) condition that a graph be just rigid is that

$$E = 2V - 3,$$

where E is the number of edges (bars) and V is the node of vertices (i.e., pivots; Coxeter and Greitzer 1967, p. 56).

Kac Formula

The expected number of REAL zeros E_n of a RANDOM POLYNOMIAL of degree n if the coefficients are independent and distributed normally is given by

$$E_n = \frac{1}{\pi}\int_{-\infty}^{\infty}\sqrt{\frac{1}{(t^2-1)^2}-\frac{(n+1)^2 t^{2n}}{(t^{2n+2}-1)^2}}\,dt \qquad (1)$$

$$= \frac{4}{\pi}\int_0^1\sqrt{\frac{1}{(1-t^2)^2}-\frac{(n+1)^2 t^{2n}}{(1-t^{2n+2})^2}}\,dt. \qquad (2)$$

(Kac 1943, Edelman and Kostlan 1995). Another form of the equation is given by

$$E_n = \frac{1}{\pi}\int_{-\infty}^{\infty}\sqrt{\left[\frac{\partial^2}{\partial x\,\partial y}\ln\frac{1-(xy)^{n+1}}{1-xy}\right]_{x=y=t}}\,dt \qquad (3)$$

(Kostlan 1993, Edelman and Kostlan 1995). As $n \to \infty$,

$$E_n = \frac{2}{\pi}\ln n + C_1 + \frac{2}{\pi n} + \mathcal{O}(n^{-2}), \qquad (4)$$

where

$$C_1 = \frac{2}{\pi}\left\{\ln 2 + \int_0^\infty\left[\sqrt{\frac{1}{x^2}-\frac{4e^{-2x}}{(1-e^{-2x})^2}}-\frac{1}{x+1}\right]dx\right\}$$
$$= 0.6257358072\ldots. \qquad (5)$$

The initial term was derived by Kac (1943).

Kac Matrix

The $(n+1)\times(n+1)$ TRIDIAGONAL MATRIX (also called the CLEMENT MATRIX) defined by

$$S_n = \begin{bmatrix} 0 & n & 0 & 0 & \cdots & 0\\ 1 & 0 & n-1 & 0 & \cdots & 0\\ 0 & 2 & 0 & n-2 & \cdots & 0\\ \vdots & \vdots & \ddots & \ddots & \ddots & \vdots\\ 0 & 0 & 0 & n-1 & 0 & 1\\ 0 & 0 & 0 & 0 & n & 0\end{bmatrix}.$$

The EIGENVALUES are $2k-n$ for $k = 0, 1, \ldots, n$.

Kadomtsev-Petviashvili Equation

The PARTIAL DIFFERENTIAL EQUATION

$$\tfrac{3}{4}\mathcal{U}_y + \mathcal{W}_x = 0, \qquad (1)$$

where

$$\mathcal{W}_y + \mathcal{U}_t - \tfrac{1}{4}\mathcal{U}_{xxx} + \tfrac{3}{2}\mathcal{U}\mathcal{U}_x = 0 \qquad (2)$$

(Krichever and Novikov 1980; Novikov 1999). Zwillinger (1997, p. 131) and Calogero and Degasperis (1982, p. 54) give the equation as

$$\frac{\partial}{\partial x}(u_t + u_{xxx} - 6uu_x) \pm u_{yy} = 0. \qquad (3)$$

The modified Kadomtsev-Petviashvili equation is given by

$$u_{xt} = u_{xxx} + 3u_{yy} - 6u_x^2 u_{xx} - 6u_y u_{xx} \qquad (4)$$

(Clarkson 1986; Zwillinger 1997, p. 133).

Kähler Form

A CLOSED TWO-FORM ω on a COMPLEX MANIFOLD M which is also the negative IMAGINARY PART of a HERMITIAN METRIC $h = g - i\omega$ is called a Kähler form. In this case, M is called a KÄHLER MANIFOLD and g, the REAL PART of the HERMITIAN METRIC, is called a KÄHLER METRIC. The Kähler form combines the metric and the COMPLEX STRUCTURE, indeed

$$g(X, Y) = \omega(X, JY), \tag{1}$$

where J is the ALMOST COMPLEX STRUCTURE induced by multiplication by i. Since the Kähler form comes from a HERMITIAN METRIC, it is preserved by J, i.e., since $h(X, Y) = h(JX, JY)$. The equation $d\omega = 0$ implies that the metric and the complex structure are related. It gives M a KÄHLER STRUCTURE, and has many implications.

On $\mathbb{C}^2$, the Kähler form can be written as

$$\omega = -\tfrac{1}{2} i(dz_1 \wedge \overline{dz_1} + dz_2 \wedge \overline{dz_2}) = dx_1 \wedge dy_1 + dx_2 \wedge dy_2, \tag{2}$$

where $z_n = x_n + iy_n$. In general, the Kähler form can be written in coordinates

$$\omega = \sum g_{i\bar{k}}\, dz_i \wedge d\bar{z}_k, \tag{3}$$

where $g_{i\bar{k}}$ is a HERMITIAN METRIC, the REAL PART of which is the KÄHLER METRIC. Locally, a Kähler form can be written as $\partial\bar{\partial} f$, where f is a function called a KÄHLER POTENTIAL. The Kähler form is a real (1, 1)-COMPLEX FORM.

Since the Kähler form ω is closed, it represents a COHOMOLOGY CLASS in DE RHAM COHOMOLOGY. On a COMPACT MANIFOLD, it cannot be EXACT because $\omega^n/n! \neq 0$ is the volume form determined by the metric. In the special case of a PROJECTIVE VARIETY, the Kähler form represents an INTEGRAL COHOMOLOGY CLASS. That is, it integrates to an integer on any one-dimensional submanifold, i.e., an ALGEBRAIC CURVE. The KODAIRA EMBEDDING THEOREM says that if the Kähler form represents an INTEGRAL COHOMOLOGY CLASS on a compact manifold, then it must be a PROJECTIVE VARIETY. There exist Kähler forms which are not projective algebraic, but it is an open question whether or not any KÄHLER MANIFOLD can be deformed to a PROJECTIVE VARIETY (in the compact case).

A Kähler form satisfies WIRTINGER'S INEQUALITY,

$$|\omega(X, Y)| \leq |X \wedge Y|, \tag{4}$$

where the right-hand side is the volume of the parallelogram formed by the tangent vectors X and Y. Corresponding inequalities hold for the EXTERIOR POWERS of ω. Equality holds IFF X and Y form a complex subspace. Therefore, ω is a CALIBRATION FORM, and the complex submanifolds of a Kähler manifold are CALIBRATED SUBMANIFOLDS. In particular, the complex submanifolds are locally volume minimizing in a Kähler manifold. For example, the graph of a holomorphic function is a locally area-minimizing surface in $\mathbb{C}^2 \simeq \mathbb{R}^4$.

Kähler Identities

A collection of identities which hold on a KÄHLER MANIFOLD, also called the Hodge identities. Let ω be a KÄHLER FORM, $d = \partial + \bar{\partial}$ be the EXTERIOR DERIVATIVE, where $\bar{\partial}$ is the DEL BAR OPERATOR, $[A, B] = AB - BA$ be the COMMUTATOR of two differential operators, and A^* denote the FORMAL ADJOINT of A. The following operators also act on DIFFERENTIAL FORMS on a KÄHLER MANIFOLD:

$$L(\alpha) = \alpha \wedge \omega \tag{1}$$

$$\Lambda(\alpha) = L^*(\alpha) = \alpha \lrcorner \omega \tag{2}$$

$$d_c = -JdJ, \tag{3}$$

where J is the ALMOST COMPLEX STRUCTURE, $J^2 = -I$,

and ⌟ denotes the INTERIOR PRODUCT. Then

$$[L, \bar{\partial}] = [L, \partial] = 0 \tag{4}$$

$$[\Lambda, \bar{\partial}^*] = [\Lambda, \partial^*] = 0 \tag{5}$$

$$[L, \bar{\partial}^*] = -i\partial \tag{6}$$

$$[L, \partial^*] = i\bar{\partial} \tag{7}$$

$$[\Lambda, \bar{\partial}] = -i\partial^* \tag{8}$$

$$[\Lambda, \partial] = i\bar{\partial}. \tag{9}$$

In addition,

$$d^* d_c = -d_c d^* = d^* L d^* = -d_c \Lambda d_c \tag{10}$$

$$d d_c{}^* = -d_c{}^* d = d_c{}^* L d_c{}^* = -d \Lambda d \tag{11}$$

$$\partial\bar{\partial}^* = -\bar{\partial}^*\partial = -i\bar{\partial}^* L \bar{\partial}^* = -i\partial\Lambda\partial \tag{12}$$

$$\bar{\partial}\partial^* = -\partial^*\bar{\partial} = i\partial^* L \partial^* = i\bar{\partial}\Lambda\bar{\partial}. \tag{13}$$

These identities have many implications. For instance, the two operators

$$\Delta_d = dd^* + d^* d \tag{14}$$

and

$$\Delta_{\bar{\partial}} = \bar{\partial}\bar{\partial}^* + \bar{\partial}^*\bar{\partial} \tag{15}$$

(called Laplacians because they are elliptic operators) satisfy $\Delta_d = 2\Delta_{\bar{\partial}}$. At this point, assume that M is also a COMPACT MANIFOLD. Along with HODGE'S THEOREM, this equality of Laplacians proves the HODGE DECOMPOSITION. The operators L and Λ commute with these Laplacians. By HODGE'S THEOREM, they act on cohomology, which is represented by HARMONIC FORMS. Moreover, defining

$$H = [L, \Lambda] = \sum (p + q - n)\Pi^{p,\,q}, \tag{16}$$

where $\Pi^{p,\,q}$ is projection onto the $(p,\,q)$-DOLBEAULT COHOMOLOGY, they satisfy

$$[L, \Lambda] = H \tag{17}$$

$$[H, L] = -2L \tag{18}$$

$$[H, \Lambda] = 2\Lambda. \tag{19}$$

In other words, these operators provide a REPRESENTATION of the SPECIAL LINEAR LIE ALGEBRA $\mathfrak{sl}_2(\mathbb{C})$ on the complex cohomology of a compact Kähler manifold. In effect, this is the content of the HARD LEFSCHETZ THEOREM.

Kähler Manifold

A COMPLEX MANIFOLD for which the EXTERIOR DERIVATIVE of the fundamental form Ω associated with the given HERMITIAN METRIC vanishes, so $d\Omega = 0$. In other words, it is a complex manifold with a KÄHLER STRUCTURE. It has a KÄHLER FORM, so it is also a SYMPLECTIC MANIFOLD. It has a KÄHLER METRIC, so it is also a RIEMANNIAN MANIFOLD.

The simplest example of a Kähler manifold is a RIEMANN SURFACE, which is a COMPLEX MANIFOLD of dimension 1. In this case, the IMAGINARY PART of any HERMITIAN METRIC must be a CLOSED FORM since all 2-forms are CLOSED on a two real dimensional MANIFOLD.

Kähler Metric

A Kähler metric is a RIEMANNIAN METRIC g on a COMPLEX MANIFOLD which gives M a KÄHLER STRUCTURE, i.e., it is a KÄHLER MANIFOLD with a KÄHLER FORM. However, the term "Kähler metric" can also refer to the corresponding HERMITIAN METRIC $h = g - i\omega$, where ω is the KÄHLER FORM, defined by $\omega(X, Y) = g(JX, Y)$. Here, the operator J is the ALMOST COMPLEX STRUCTURE, a linear map on tangent vectors satisfying $J^2 = -I$, induced by multiplication by i. In coordinates $z_k = x_k + iy_k$, the

operator J satisfies $J(\partial/\partial x_k) = \partial/\partial y_k$ and $J(\partial/\partial y_k) = -\partial/\partial x_k$.

The operator J depends on the COMPLEX STRUCTURE, and on a KÄHLER MANIFOLD, it must preserve the Kähler metric. For a metric to be Kähler, one additional condition must also be satisfied, namely that it can be expressed in terms of the metric and the complex structure. Near any point p, there exists holomorphic coordinates $z_k = x_k + iy_k$ such that the metric has the form

$$g = \sum dx_k \otimes dx_k + dy_k \otimes dy_k + \mathcal{O}(|z|^2),$$

where $\otimes$ denotes the TENSOR PRODUCT; that is, it vanishes up to order two at p. Hence, any geometric equation in $\mathbb{C}^n$ involving only the first derivatives can be defined on a Kähler manifold. Note that a generic metric can be written to vanish up to order two, but not necessarily in holomorphic coordinates, using a GAUSSIAN COORDINATE SYSTEM.

Kähler Potential

The Kähler potential is a real-valued function f on a KÄHLER MANIFOLD for which the KÄHLER FORM ω can be written as $\omega = i\partial\bar{\partial}f$. Here, the operators

$$\partial = \sum \frac{\partial}{\partial z_k}\, dz_k \qquad (1)$$

and

$$\bar{\partial} = \sum \frac{\partial}{\partial \bar{z}_k}\, d\bar{z}_k \qquad (2)$$

are called the del and DEL BAR OPERATOR, respectively.

For example, in $\mathbb{C}^n$, the function $f = |z|^2/2$ is a Kähler potential for the standard Kähler form, because

$$i\partial\bar{\partial}(\tfrac{1}{2}|z|^2) = \tfrac{1}{2}\, i\partial\bar{\partial} \sum z_k \bar{z}_k$$
$$= \tfrac{1}{2}\, i\partial \sum z_k\, d\bar{z}_k$$
$$= \tfrac{1}{2}\, i \sum dz_k \wedge d\bar{z}_k = \omega.$$

Kähler Structure

A Kähler structure on a COMPLEX MANIFOLD M combines a RIEMANNIAN METRIC on the underlying REAL MANIFOLD with the COMPLEX STRUCTURE. Such a structure brings together geometry and complex analysis, and the main examples come from ALGEBRAIC GEOMETRY. When M has n complex dimensions, then it has $2n$ real dimensions. A Kähler structure is related to the UNITARY GROUP $U(n)$, which embeds in $SO(2n)$ as the orthogonal matrices that preserve the ALMOST COMPLEX STRUCTURE (multiplication by 'i'). In a COORDINATE CHART, the COMPLEX STRUCTURE of M defines a multiplication by i and the metric defines orthogonality for tangent vectors. On a Kähler manifold, these two notions (and their derivatives) are related.

The following are elements of a Kähler structure, with each condition SUFFICIENT for a Kähler structure to exist.

1. A KÄHLER METRIC. Near any point p, there exists holomorphic coordinates $z_k = x_k + iy_k$ such that the metric has the form

$$g = \sum dx_k \otimes dx_k + dy_k \otimes dy_k + \mathcal{O}(|z|^2), \qquad (1)$$

where $\otimes$ denotes the TENSOR PRODUCT; that is, it vanishes up to order two at p. Hence any geometric equation in $\mathbb{C}^n$ involving only the first derivatives can be defined on a KÄHLER MANIFOLD. Note that a generic metric can be written to vanish up to order two, but not necessarily in holomorphic coordinates, using a GAUSSIAN COORDINATE SYSTEM.

2. A KÄHLER FORM ω is a real CLOSED nondegenerate TWO-FORM, i.e., a SYMPLECTIC FORM, for which $\omega(X, JX) > 0$ for nonzero tangent vectors X. Moreover, it must also satisfy $\omega(JX, JY) = \omega(X, Y)$, where J is the ALMOST COMPLEX STRUCTURE

induced by multiplication by i. That is,

$$J\left(\frac{\partial}{\partial x_k}\right) = \frac{\partial}{\partial y_k} \quad (2)$$

and

$$J\left(\frac{\partial}{\partial y_k}\right) = -\frac{\partial}{\partial x_k}. \quad (3)$$

Locally, a Kähler form can be written as $\partial\bar{\partial}f$, where f is a function called a KÄHLER POTENTIAL. The Kähler form is a real (1, 1)-FORM.

3. A HERMITIAN METRIC $h = g - i\omega$ where the REAL PART is a KÄHLER METRIC, as in item (1) above, and where the IMAGINARY PART is a KÄHLER FORM, as in item (2).

4. A metric for which the ALMOST COMPLEX STRUCTURE J is PARALLEL. Since PARALLEL TRANSPORT is always an isometry, a HERMITIAN METRIC is well-defined by PARALLEL TRANSPORT along paths from a base point. The HOLONOMY GROUP is contained in the UNITARY GROUP.

It is easy to see that a complex SUBMANIFOLD of a KÄHLER MANIFOLD inherits its Kähler structure, and so must also be Kähler. The main source of examples are PROJECTIVE VARIETIES, complex submanifolds of COMPLEX PROJECTIVE SPACE which are solutions to algebraic equations.

There are several deep consequences of the Kähler condition. For example, the KÄHLER IDENTITIES, the HODGE DECOMPOSITION of COHOMOLOGY, and the LEFSCHETZ THEOREMS depend on the Kähler condition for compact manifolds.

Kakeya Needle Problem

What is the plane figure of least AREA in which a line segment of width 1 can be freely rotated (where translation of the segment is also allowed)? When the figure is restricted to be convex, Cunningham and Schoenberg (1965) found there is still *no* minimum AREA, although Wells (1991) states that Kakeya discovered that the smallest convex region is an EQUILATERAL TRIANGLE of unit height. The smallest *simple convex* domain in which one can put a segment of length 1 which will coincide with itself when rotated by 180° is

$$\tfrac{1}{24}(5 - 2\sqrt{2})\pi = 0.284258\ldots$$

(Le Lionnais 1983).

For a general convex shape, Besicovitch (1928) proved that there is *no* MINIMUM AREA. This can be seen by rotating a line segment inside a DELTOID, star-shaped 5-oid, star-shaped 7-oid, etc. Another iterative construction which tends to as small an area as desired is called a PERRON TREE (Falconer 1990, Wells 1991).

KAM Theorem

KOLMOGOROV-ARNOLD-MOSER THEOREM

Kampé de Fériet Function

A SPECIAL FUNCTION generalizes the GENERALIZED HYPERGEOMETRIC FUNCTION to two variables and includes the APPELL HYPERGEOMETRIC FUNCTION $F_1(\alpha;\ \beta,\ \beta';\ \gamma;\ x,\ y)$ as a special case. The Kampe de Feriet function can represent derivatives of GENERALIZED HYPERGEOMETRIC FUNCTIONS with respect to their parameters, as well as indefinite integrals of two and three MEIJER'S G-FUNCTIONS. Exton and Krupnikov (1998) have derived a large collection of formulas involving this function.

Kampé de Fériet functions are written in the notation

$$\mathrm{F}_{q,\ s,\ u}^{p,\ r,\ t}\left(\begin{matrix} c_p \\ d_q \end{matrix}\middle|\begin{matrix} a_r \\ b_s \end{matrix}\middle|\begin{matrix} \alpha_t \\ \beta_u \end{matrix}\middle| x,\ y\right). \tag{1}$$

Special cases include

$$\mathrm{F}_{1,\ 0,\ 0}^{1,\ 1,\ 1}\left(\begin{matrix} 1/2 \\ 3/2 \end{matrix}\middle|\begin{matrix} 1/2 \\ - \end{matrix}\middle|\begin{matrix} -1/2 \\ - \end{matrix}\middle| x,\ y\right) = \frac{1}{\sqrt{x}} E\left(\sin^{-1}(\sqrt{x}),\ \sqrt{y/x}\right) \tag{2}$$

$$\mathrm{F}_{1,\ 0,\ 0}^{1,\ 1,\ 1}\left(\begin{matrix} 1/2 \\ 3/2 \end{matrix}\middle|\begin{matrix} 1/2 \\ - \end{matrix}\middle|\begin{matrix} -1/2 \\ - \end{matrix}\middle| x,\ y\right) = \frac{1}{\sqrt{x}} F\left(\sin^{-1}(\sqrt{x}),\ \sqrt{y/x}\right) \tag{3}$$

for $x \neq 0$ and $|x|,\ |y| \leq 1$, where $E(x,\ k)$ is the incomplete ELLIPTIC INTEGRAL OF THE SECOND KIND and $F(x,\ k)$ is the incomplete ELLIPTIC INTEGRAL OF THE FIRST KIND, as well as

$$\mathrm{F}_{1,\ 0,\ 0}^{1,\ 1,\ 1}\left(\begin{matrix} 1/2 \\ 1 \end{matrix}\middle|\begin{matrix} 1 \\ - \end{matrix}\middle|\begin{matrix} 1/2 \\ - \end{matrix}\middle| x,\ y\right) = \frac{2}{\pi}\,\Pi(1;\ x,\ \sqrt{y}) \tag{4}$$

for $|x|,\ |y| < 1$, where $\Pi(n;\ x,\ k)$ is the incomplete ELLIPTIC INTEGRAL OF THE THIRD KIND (Exton and Krupnikov 1998, p. 1). Additional identities are given by

$$\mathrm{F}_{q,\ s,\ u}^{1+p,\ r,\ t}\left(\begin{matrix} 0, c_p \\ d_q \end{matrix}\middle|\begin{matrix} a_r \\ b_s \end{matrix}\middle|\begin{matrix} \alpha_t \\ \beta_u \end{matrix}\middle| x,\ y\right) = 1 \tag{5}$$

$$\mathrm{F}_{q,\ s,\ u}^{p,\ r,\ t}\left(\begin{matrix} c_p \\ d_q \end{matrix}\middle|\begin{matrix} a_r \\ b_s \end{matrix}\middle|\begin{matrix} \alpha_t \\ \beta_u \end{matrix}\middle| x,\ 0\right) = \mathrm{F}_{q+s}^{p+r}\left(\begin{matrix} c_p,\ a_r \\ d_q,\ d_s \end{matrix}\middle| x\right) \tag{6}$$

$$\mathrm{F}_{q,\ s,\ u}^{p,\ r,1+\ t}\left(\begin{matrix} c_p \\ d_q \end{matrix}\middle|\begin{matrix} a_r \\ b_s \end{matrix}\middle|\begin{matrix} 0,\ \alpha_t \\ \beta_u \end{matrix}\middle| x,\ y\right) = \mathrm{F}_{q+s}^{p+r}\left(\begin{matrix} c_p,\ a_r \\ d_q,\ d_s \end{matrix}\middle| x\right) \tag{7}$$

(Exton and Krupnikov 1998, p. 3).

Kantorovich Inequality

Suppose $x_1 < x_2 < \ldots < x_n$ are given POSITIVE numbers. Let $\lambda_1, \ldots, \lambda_n \geq 0$ and $\Sigma_{j=1}^{n} \lambda_j = 1$. Then

$$\left(\sum_{j=1}^{n} \lambda_j x_j\right)\left(\sum_{j=1}^{n} \lambda_j x_j^{-1}\right) \leq A^2 G^{-2}, \quad (1)$$

where

$$A = \tfrac{1}{2}(x_1 + x_n) \quad (2)$$

$$G = \sqrt{x_1 x_n} \quad (3)$$

are the ARITHMETIC and GEOMETRIC MEAN, respectively, of the first and last numbers. The Kantorovich inequality is central to the study of convergence properties of descent methods in optimization (Luenberger 1984).

Kaplan-Yorke Conjecture

There are several versions of the Kaplan-Yorke conjecture, with many of the higher dimensional ones remaining unsettled. The original Kaplan-Yorke conjecture (Kaplan and Yorke 1979) proposed that, for a two-dimensional mapping, the CAPACITY DIMENSION D equals the KAPLAN-YORKE DIMENSION D_{KY},

$$D = D_{KY} = d_{\text{Lya}} = 1 + \frac{\sigma_1}{\sigma_2},$$

where σ_1 and σ_2 are the LYAPUNOV CHARACTERISTIC EXPONENTS. This was subsequently proven to be true in 1982. A later conjecture held that the KAPLAN-YORKE DIMENSION is generically equal to a probabilistic dimension which appears to be identical to the INFORMATION DIMENSION (Frederickson *et al.* 1983). This conjecture is partially verified by Ledrappier (1981). For invertible 2-D maps, $\nu = \sigma = D$, where ν is the CORRELATION EXPONENT, σ is the INFORMATION DIMENSION, and D is the CAPACITY DIMENSION (Young 1984).

Kaplan-Yorke Dimension

$$D_{\mathrm{KY}} \equiv j + \frac{\sigma_1 + \ldots + \sigma_j}{|\sigma_{j+1}|},$$

where $\sigma_1 \le \sigma_n$ are LYAPUNOV CHARACTERISTIC EXPONENTS and j is the largest INTEGER for which

$$\lambda_1 + \ldots + \lambda_j \ge 0.$$

If $\nu = \sigma = D$, where ν is the CORRELATION EXPONENT, σ the INFORMATION DIMENSION, and D the HAUSDORFF DIMENSION, then

$$D \le D_{\mathrm{KY}}$$

(Grassberger and Procaccia 1983).

Kappa Curve

A curve also known as GUTSCHOVEN'S CURVE which was first studied by G. van Gutschoven around 1662 (MacTutor Archive). It was also studied by Newton and, some years later, by Johann Bernoulli. It is given by the Cartesian equation

$$(x^2 + y^2)y^2 = a^2x^2, \quad (1)$$

by the polar equation

$$r = a \cot \theta, \quad (2)$$

and the PARAMETRIC EQUATIONS

$$x = a \cos t \cot t \quad (3)$$

$$y = a \cos t. \quad (4)$$

Kaprekar Number

Consider an n-digit number k. Square it and add the right n digits to the left n or $n-1$ digits. If the resultant sum is k, then k is called a Kaprekar number. The first few are 1, 9, 45, 55, 99, 297, 703, ... (Sloane's A006886).

$$9^2 = 81 \quad 8 + 1 = 9$$

$$297^2 = 88,209 \quad 88 + 209 = 297.$$

Kaprekar Routine

A routine discovered in 1949 by D. R. Kaprekar for 4-digit numbers, but which can be generalized to k-digit numbers. To apply the Kaprekar routine to a number n, arrange the digits in descending (n') and ascending (n'') order. Now compute $K(n) \equiv n' - n''$ and iterate. The algorithm reaches 0 (a degenerate case), a constant, or a cycle, depending on the number of digits in k and the value of n.

For a 3-digit number n in base 10, the Kaprekar routine reaches the number 495 in at most six

iterations. In base r, there is a unique number $((r-2)/2,\ r-1,\ r/2)_r$ to which n converges in at most $(r+2)/2$ iterations IFF r is EVEN. For any 4-digit number n in base-10, the routine terminates on the number 6174 after seven or fewer steps (where it enters the 1-cycle $K(6174)=6174$).

Karatsuba Multiplication

It is possible to perform MULTIPLICATION of LARGE NUMBERS in (many) fewer operations than the usual brute-force technique of "long multiplication." As discovered by Karatsuba and Ofman (1962), MULTIPLICATION of two n-DIGIT numbers can be done with a BIT COMPLEXITY of less than n^2 using identities OF THE FORM

$$\begin{aligned}(a+b\cdot 10^n)(c+d\cdot 10^n)\\ = ac + [(a+b)(c+d)-ac-bd]10^n + bd\cdot 10^{2n}.\end{aligned} \quad (1)$$

Proceeding recursively then gives BIT COMPLEXITY $\mathcal{O}(n^{\lg 3})$, where $\lg 3 = 1.58\ldots < 2$ (Borwein *et al.* 1989). The best known bound is $\mathcal{O}(n \lg n \lg n)$ steps for $n \gg 1$ (Schönhage and Strassen 1971, Knuth 1981). However, this ALGORITHM is difficult to implement, but a procedure based on the FAST FOURIER TRANSFORM is straightforward to implement and gives BIT COMPLEXITY $\mathcal{O}((\lg n)^{2+\epsilon} n)$ (Brigham 1974, Borodin and Munro 1975, Knuth 1981, Borwein *et al.* 1989).

As a concrete example, consider MULTIPLICATION of two numbers each just two "digits" long in base w,

$$N_1 = a_0 + a_1 w \quad (2)$$

$$N_2 = b_0 + b_1 w, \quad (3)$$

then their PRODUCT is

$$P \equiv N_1 N_2 = a_0 b_0 + (a_0 b_1 + a_1 b_0) w + a_1 b_1 w^2 = p_0 + p_1 w + p_2 w^2. \quad (4)$$

Instead of evaluating products of individual digits, now write

$$q_0 = a_0 b_0 \quad (5)$$

$$q_1 = (a_0 + a_1)(b_0 + b_1) \quad (6)$$

$$q_2 = a_1 b_1. \quad (7)$$

The key term is q_1, which can be expanded, regrouped, and written in terms of the p_j as

$$q_1 = p_1 + p_0 + p_2. \quad (8)$$

However, since $p_0 = q_0$, and $p_2 = q_2$, it immediately follows that

$$p_0 = q_0 \quad (9)$$

$$p_1 = q_1 - q_0 - q_2 \quad (10)$$

$$p_2 = q_2, \quad (11)$$

so the three "digits" of p have been evaluated using three multiplications rather than four. The technique can be generalized to multidigit numbers, with the trade-off being that more additions and subtractions are required.

Now consider four-"digit" numbers

$$N_1 = a_0 + a_1 w + a_2 w^2 + a_3 w^3, \quad (12)$$

which can be written as a two-"digit" number represented in the base w^2,

$$N_1 = (a_0 + a_1 w) + (a_2 + a_3 w) * w^2. \quad (13)$$

The "digits" in the new base are now

$$a'_0 = a_0 + a_1 w \quad (14)$$

$$a'_1 = a_2 + a_3 w, \quad (15)$$

and the Karatsuba algorithm can be applied to N_1 and N_2 in this form. Therefore, the Karatsuba algorithm is not restricted to multiplying two-digit numbers, but more generally expresses the multiplication of two numbers in terms of multiplications of numbers of half the size. The asymptotic speed the algorithm obtains by recursive application to the smaller required subproducts is $\mathcal{O}(n^{\lg 3})$ (Knuth 1981).

When this technique is recursively applied to multidigit numbers, a point is reached in the recursion when the overhead of additions and subtractions makes it more efficient to use the usual $\mathcal{O}(n^2)$ MULTIPLICATION algorithm to evaluate the partial products. The most efficient overall method therefore relies on a combination of Karatsuba and conventional multiplication.

Karnaugh Map

In combinatorial logic minimization, a device known as a Karnaugh map is frequently used. It is similar to a TRUTH TABLE, but the various variables are represented along two axes, and are arranged in such a way that only one input bit changes in going from one square to an adjacent square.

See also TRUTH TABLE

k-ary Divisor

Let a DIVISOR d of n be called a 1-ary divisor if $d \perp nd$ (i.e., d is RELATIVELY PRIME to n/d). Then d is called a k-ary divisor of n, written $d|_k n$, if the GREATEST COMMON $(k-1)$-ary divisor of d and (n/d) is 1.

In this notation, $d\|n$ is written $d|_0 n$, and $d\|n$ is written $d|_1 n$. p^x is an INFINARY DIVISOR of p^y (with $y > 0$) if $p^x|_{y-1} p^y$.

Katadrome

A katadrome is a number whose HEXADECIMAL digits are in strict descending order. The first few are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 32, 33, 48, 49, ... (Sloane's A023797), corresponding to 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F, 10, 20, 21, 30, 31, ...

See also DIGIT, HEXADECIMAL, METADROME, NIALPDROME, PLAINDROME

Katona's Problem

Find the minimum number $f(n)$ of SUBSETS in a SEPARATING FAMILY for a SET of n elements, where a SEPARATING FAMILY is a SET of SUBSETS in which each pair of adjacent elements is found separated, each in one of two DISJOINT SUBSETS. For example, the 26 letters of the alphabet can be separated by a family of nine:

$$\begin{matrix} (abcdefghi) & (jklmnopqr) & (stuvwxyz) \\ (abcjklstu) & (defmnovwx) & (ghipqryz) \\ (adgjmpsvy) & (behknqtwz) & (cfilorux) \end{matrix}.$$

The problem was posed by Katona (1973) and solved by C. Mao-Cheng in 1982,

$$f(n) = \min\left\{2p + 3\left\lceil \log_3\left(\frac{n}{2^p}\right)\right\rceil : p = 0,\ 1,\ 2\right\},$$

where $\lceil x \rceil$ is the CEILING FUNCTION. $f(n)$ is nondecreasing, and the values for $n = 1, 2, ...$ are 0, 2, 3, 4, 5, 5, 6, 6, 6, 7, ... (Sloane's A007600). The values at which $f(n)$ increases are 1, 2, 3, 4, 5, 7, 10, 13, 19, 28, 37, ... (Sloane's A007601), so $f(26) = 9$, as illustrated in the preceding example.

Kauffman Polynomial F

A semi-oriented 2-variable KNOT POLYNOMIAL defined by

$$F_L(a,\ z) = a^{-w(L)}\langle |L| \rangle, \tag{1}$$

where L is an oriented LINK DIAGRAM, $w(L)$ is the WRITHE of L, $|L|$ is the unoriented diagram corresponding to L, and $\langle L \rangle$ is the BRACKET POLYNOMIAL. It was developed by Kauffman by extending the BLM/HO POLYNOMIAL Q to two variables, and satisfies

$$F(1,\ x) = Q(x). \tag{2}$$

The Kauffman POLYNOMIAL is a generalization of the JONES POLYNOMIAL $V(t)$ since it satisfies

$$V(t) = F(-t^{-3/4},\ t^{-1/4} + t^{1/4}), \tag{3}$$

but its relationship to the HOMFLY POLYNOMIAL is not well understood. In general, it has more terms than the HOMFLY POLYNOMIAL, and is therefore more powerful for discriminating KNOTS. It is a semi-oriented POLYNOMIAL because changing the orientation only changes F by a POWER of a. In particular, suppose L^* is obtained from L by reversing the orientation of component k, then

$$F_{L^*} = a^{4\lambda} F_L, \tag{4}$$

where λ is the LINKING NUMBER of k with $L - k$ (Lickorish and Millett 1988). F is unchanged by MUTATION.

$$F_{L_1 + F_{L_2}} = F(L_1)F(L_2) \tag{5}$$

$$F_{L_1 \cup L_2} = [(a^{-1} + a)x^{-1} - 1]F_{L_1}F_{L_2}. \tag{6}$$

M. B. Thistlethwaite has tabulated the Kauffman 2-variable POLYNOMIAL for KNOTS up to 13 crossings.

Kauffman Polynomial X

A 1-variable KNOT POLYNOMIAL denoted X or $\mathscr{L}$.

$$\mathscr{L}_L(A) \equiv (-A^3)^{-w(L)}\langle L \rangle, \tag{1}$$

where $\langle L \rangle$ is the BRACKET POLYNOMIAL and $w(L)$ is the WRITHE of L. This POLYNOMIAL is invariant under AMBIENT ISOTOPY, and relates MIRROR IMAGES by

$$\mathscr{L}_{L^*} = \mathscr{L}_L(A^{-1}). \quad (2)$$

It is identical to the JONES POLYNOMIAL with the change of variable

$$\mathscr{L}(t^{-1/4}) = V(t). \quad (3)$$

The X POLYNOMIAL of the MIRROR IMAGE K^* is the same as for K but with A replaced by A^{-1}.

k-Connected Graph

A graph G is said to be k-connected if there does not exist a set of $k-1$ vertices whose removal disconnects the graph, i.e., the VERTEX CONNECTIVITY of G is $\geq k$ (Skiena 1990, p. 177). Therefore, a CONNECTED GRAPH is 1-connected, and a BICONNECTED GRAPH is 2-connected (Skiena 1990, p. 177).

The following table gives the numbers of k-connected graphs for n-node graphs. Note that there is a unique n-connected n-node graph, namely, the COMPLETE GRAPH K_n. The WHEEL GRAPH is the basic 3-connected graph (Tutte 1961; Skiena 1990, p. 179).

k	k-connected graphs on 1, 2, ... nodes
1	1, 1, 2, 6, 21, 112, 853, ...
2	0, 1, 1, 3, 10, 56, 468, ...
3	0, 0, 1, 1, 3, 17, 136, ...
4	0, 0, 0, 1, 1, 4, 25, ...
5	0, 0, 0, 0, 1, 1, 4, ...
6	0, 0, 0, 0, 0, 1, 1, ...
7	0, 0, 0, 0, 0, 0, 1, ...
8	0, 0, 0, 0, 0, 0, 0, ...

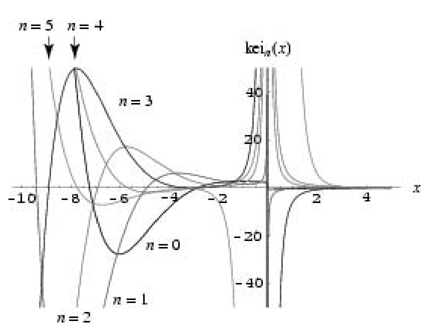
k-Edge-Connected Graph

A graph is k-edge-connected if there does not exist a set of k edges whose removal disconnects the graph (Skiena 1990, p. 177). The maximum edge connectivity of a given graph is the smallest degree of any node, since deleting these edges disconnects the graph. Complete bipartite graphs have maximum edge connectivity. The following table gives the numbers of k-edge-connected graphs for n-node graphs.



k	Sloane	$n = 1, 2, ...$
0	A000719	0, 1, 2, 5, 13, 44, 191, ...
1	A052446	0, 1, 1, 3, 10, 52, 351, ...
2	A052447	0, 0, 1, 2, 8, 41, 352, ...
3	A052448	0, 0, 0, 1, 2, 15, 121, ...
4		0, 0, 0, 0, 1, 3, 25, ...
5		0, 0, 0, 0, 0, 1, 3, ...
6		0, 0, 0, 0, 0, 0, 1, ...

Keith Number

A Keith number is an n-digit INTEGER N such that if a Fibonacci-like sequence (in which each term in the sequence is the sum of the n previous terms) is formed with the first n terms taken as the decimal digits of the number N, then N itself occurs as a term in the sequence. For example, 197 is a Keith number since it generates the sequence 1, 9, 7, 17, 33, 57, 107, 197, ... (Keith). Keith numbers are also called REPFIGIT NUMBERS.

There is no known general technique for finding Keith numbers except by exhaustive search. Keith numbers are much rarer than the PRIMES, with only 52 Keith numbers with < 15 digits: 14, 19, 28, 47, 61, 75, 197, 742, 1104, 1537, 2208, 2580, 3684, 4788, 7385, 7647, 7909, ... (Sloane's A007629). The number of Keith numbers having $n = 1, 2, ...$ digits are 0, 6, 2, 9, 7, 10, 2, 3, 2, 0, 2, 4, 2, 3, 3, 3, 5, 3, 5, ... (Sloane's A050235; Keith), so there are only 71 less than 10^{19}. It is not known if there are an INFINITE number of Keith numbers.

The known prime Keith numbers are 19, 47, 61, 197, 1084051, 74596893730427, ... (Sloane's A048970).

Kelvin Functions

Kelvin defined the Kelvin functions BEI and BER according to

$$\operatorname{ber}_\nu(x) + i \operatorname{bei}_\nu(x) = J_\nu(xe^{3\pi i/4}) \tag{1}$$

$$= e^{\nu\pi i} J_\nu(xe^{-\pi i/4}), \tag{2}$$

$$= e^{\nu\pi i/2} I_\nu(xe^{\pi i/4}) \tag{3}$$

$$= e^{3\nu\pi i/2} I_\nu(xe^{-3\pi i/4}), \tag{4}$$

where $J_\nu(x)$ is a BESSEL FUNCTION OF THE FIRST KIND and $I_\nu(x)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND. These functions satisfy the KELVIN DIFFERENTIAL EQUATION.

Similarly, the functions KEI and KER by

$$\operatorname{ker}_\nu(x) + i \operatorname{kei}_\nu(x) = e^{-\nu\pi i/2} K_\nu(xe^{\pi i/4}), \tag{5}$$

where $K_\nu(x)$ is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND. For the special case $\nu = 0$,

$$J_0\left(i\sqrt{i}x\right) = J_0\left(\tfrac{1}{2}\sqrt{2}(i-1)x\right) \equiv \operatorname{ber}(x) + i \operatorname{bei}(x). \tag{6}$$

Kelvin Problem

KELVIN'S CONJECTURE

Kelvin Transformation

Let D be a DOMAIN in $\mathbb{R}^n$ for $n \geq 3$. Then the transformation

$$v(x'_1, \ldots, x'_n) = \left(\frac{a}{r'}\right)^{n-2} u\left(\frac{a^2 x'_1}{r'^2}, \ldots, \frac{a^2 x'_n}{r'^2}\right)$$

onto a domain D', where

$$r'^2 = x_1'^2 + \ldots + x_n'^2$$

is called a Kelvin transformation. If $u(x_1, \ldots, x_n)$ is a HARMONIC FUNCTION on D, then $v(x'_1, \ldots, x'_n)$ is also HARMONIC on D'.

See also HARMONIC FUNCTION

References

Itô, K. (Ed.). "Harmonic Functions and Subharmonic Functions: Invariance of Harmonicity." §193B in *Encyclopedic Dictionary of Mathematics, 2nd ed.* Cambridge, MA: MIT Press, p. 725, 1980.

Kelvin's Conjecture

What space-filling arrangement of similar polyhedral cells of equal volume has minimal SURFACE AREA? Kelvin (Thomson 1887) proposed that the solution was the 14-sided TRUNCATED OCTAHEDRON. The isoperimetric quotient for the TRUNCATED OCTAHEDRON is given by

$$Q = \frac{36\pi V^3}{S^2} = \frac{36\pi(8\sqrt{2})^2}{(6 + 12\sqrt{3})^3}$$

$$= \frac{64\pi}{3(1 + 2\sqrt{3})^3} \approx 0.753367.$$

Despite one hundred years of failed attempts and Weyl's (1952) opinion that the TRUNCATED OCTAHEDRON could not be improved upon, Weaire and Phelan (1994) discovered a space-filling unit cell consisting of six 14-sided polyhedra and two 12-sided polyhedra that has 0.3% less SURFACE AREA.

Kepler Conjecture

In 1611, Kepler proposed that close packing (cubic or hexagonal) is the densest possible SPHERE PACKING (has the greatest η), and this assertion is known as the Kepler conjecture. Finding the densest (not necessarily periodic) packing of spheres is known as the KEPLER PROBLEM.

Buckminster Fuller (1975) claimed to have a proof, but it was really a description of face-centered cubic packing, not a proof of its optimality (Sloane 1998). A second putative proof of the Kepler conjecture was put forward by W.-Y. Hsiang (Cipra 1991, Hsiang 1992, Hsiang 1993, Cipra 1993), but was subsequently determined to be flawed (Conway *et al.* 1994, Hales 1994, Sloane 1998). According to J. H. Conway, nobody who has read Hsiang's proof has any doubts about its validity: it is nonsense.

Soon thereafter, Hales (1997a) published a detailed plan describing how the Kepler conjecture might be proved using a significantly different approach from earlier attempts and making extensive use of computer calculations. Hales subsequently completed a full proof, which appears in a series of papers totaling more than 250 pages (Cipra 1998) The proof relies extensively on methods from the theory of global optimization, linear programming, and interval arithmetic. The computer files containing the computer code and data files for combinatorics, interval arithmetic, and linear programs require over 3 gigabytes of space for storage.
